A

DICTIONARY

OF

ARTS AND SCIENCES.

BY G. GREGORY, D.D.

DOCTOR IN PHILOSOPHY AND THE ARTS, AND HONORARY MEMBER OF THE IMPERIAL UNIVERSITY OF WILNA; MEMBER OF THE MANCHESTER AND NEWCASTLE LITERARY AND PHILOSOPHICAL SOCIETIES; HONORARY MEMBER OF THE BOARD OF AGRICULTURE; DOMESTIC CHAPLAIN TO THE LORD BISHOP OF LLANDAFF; AUTHOR OF ESSAYS HISTORICAL AND MORAL, THE ECONOMY OF NATURE,

&c. &c.

IN TWO VOLUMES.

VOL. II.

LONDON:

PRINTED FOR RICHARD PHILLIPS,

NO. 6, BRIDGE-STREET, BLACKFRIARS.

1807.

T. Gillet, Printer, Wild-Court.

TO THE RIGHT HONOURABLE

THOMAS, LORD ERSKINE,

BARON ERSKINE OF RESTORMEL CASTLE, IN THE COUNTY OF CORNWALL,

LORD HIGH CHANCELLOR OF GREAT BRITAIN,

&c. &c. &c.

MY LORD,

THOUGH a Dedication is in general an expression of gratitude from an Author to his Patron, or of friendship from one literary character to another, yet I cannot but be of opinion, that there should be some accord between the character of the Work and that of the Patron to whom it is presented.

In this point of view the world will see the propriety of a Work which professes to treat of the Sciences and the Arts in general, being inscribed to a Nobleman who unites in himself more various, as well as more splendid talents, more general knowledge, and more diversified taste, than any other public character of the present age; who, deservedly filling the chair of Bacon, possesses the same excursive and expanded genius; but whose public duties, being more onerous than they were in the time of that great man, alone preclude him from gratifying and enlightening the Public by researches out of the line of his profession.

If a private sentiment might be indulged on such an occasion, the Editor would add, that your Lordship's unremitted zeal for true Religion, and your tried and disinterested Patriotism, must for ever endear the name of ERSKINE toevery friend of liberty, piety, and active virtue.

That your Lordship may long continue to serve your country, and promote the best interests of humanity, in the arduous situation to which the Divine Providence has been pleased to call you, is the fervent prayer of,

My Lord,

Your Lordship's

Ever faithful humble servant,

G. GREGORY.

West Ham, Jan. 20, 1807.

PREFACE.

FROM the time of Chambers, Dictionaries of Arts and Sciences have been increasing in magnitude, without (it is to be feared) a proportionable increase of utility. The authors appear to have regarded it as a kind of sacrilege to retrench, while they have equally thought it their duty to add every thing that came within their reach. Hence not only obsolete terms, but obsolete sciences, as magic, alchemy, and astrology, have been retained even in works of high character, and otherwise of distinguished merit. Hence, that which was new even in the living sciences, has been combined with what had been long since exploded: a practice calculated not only to confuse but to mislead.

It was upon this view of the subject it occurred to the editor of this work, that in framing a new Dictionary, selection was a more urgent duty than accumulation; that perspicuity, not less than convenience, would be consulted by reducing the size; and that whatever is practically useful in science and in art might be compressed within a smaller compass than had been commonly imagined. However deficient he may have been in the execution of his plan, he has the satisfaction to say, that in this idea he was not deceived or disappointed.

A dictionary of this kind is intended for two purposes: first, as a book of reference, to lie on the table of a man of letters, for occasional consultation where recollection has failed, or where a subject occurs in reading or conversation which had not previously come within the course of his studies. The second is, to serve as an introductory or elementary work for students, or for those who may not have leisure to bestow on the great works of science, or to travel through the many volumes which at this time almost every branch of knowledge includes.

The first of these ends it is humbly presumed will be sufficiently answered by the present publication. Most of the technical terms in science and the arts, are inserted with a proper definition or explanation, in the alphabetical order; or should there be a casual omission, the word will still be found under the head of the science to which it belongs, and probably in the index to the treatises at the end of each volume. To some sciences it was found necessary to attach a glossary. The technical phrases, however, in anatomy, surgery, &c. are generally referred to those branches of science expressly treating of them, that nothing may appear, on casually opening the book, to offend the most modest or delicate reader. Terms also which now constitute a part of common colloquial language, and which, therefore, every person must understand, have been omitted.

With respect to the second object, no pains have been spared in preparing those articles which treat of the respective sciences. In a work of this nature it cannot be expected that the whole should be original, nor could it in that case answer so well the ends for which it is designed. An Encyclopedia is in its nature a compilation; and its best commendation is, that it amasses together the best information from the best sources. Yet in this work there is much original composition; and such is the progress of science, that it contains scarcely any articles of importance which are to be found in any similar publication.

In order also to facilitate as much as possible the study of the sciences, every attention, consistent with the nature of the work, has been paid to method; and the student will not be much at a loss to distinguish the order in which the several parts of each science are to be read. Thus, under Natural History, he will find a synopsis of the several branches, the classes and orders, and under these the names of the genera; under Zoology, again, he will not only meet the classes and orders, but also an immediate reference to the genera. Under Chemistry, he will find the outlines of the science, and references to the different branches, which are treated more at large in other parts of the work. Thus under Furnace and Laboratory, is included the whole of the apparatus; and he will then turn to Air, and the simple substances as they stand enumerated there, or under the word Elements. Astronomy and Mineralogy, he will see, have similar references. Electricity, Hydrostatics, Hydraulics, Magnetism, Mechanics, Meteorology, Optics, Pneumatics, and the Medical Branches, are complete in themselves. Those articles which relate to the Arts are also complete. Those which treat of the different subjects of Trade and Commerce are also complete, and contain all the new information which could be obtained on those important topics.

The Editor cannot conclude this address without frankly stating, that whatever may be thought of the merits of the new Dictionary of Arts and Sciences, they are more to be attributed to the very able assistance with which he has been favoured from different quarters, than to his own exertions. He wishes he could make his acknowledgments in terms equal to his sense of the obligation. To his industrious and truly able coadjutor, the Rev. Mr. Joyce, he is indebted for much general assistance, and for the exclusive superintendance of all the mathematical and astronomical articles. A similar acknowledgment is due to his friend and neighbour, Luke Howard, Esq. particularly for his attention to all those articles connected with the almost new, and important science, Meteorology.

The public will estimate better than he can point out the extent of his and their obligations to Mr. Grellier, of the Royal Exchange Assurance-Office, when he mentions, that all the articles relative to Trade, Commerce, Political Economy, Finance, and Revenue, were drawn up by that gentleman.

The Medical and Physiological articles were written by Dr. Uwins, of Somers Town; Husbandry and Surveying by Mr. Crocker, of Froome; Rhetoric by Dr. Thomson, well known as the Continuator of Watson's History; Architecture by Mr. Henderson, the plates by Mr. Moore; Exchanges by Mr. P. Hamsbrow; Farriery by Mr. Lawrence; and Anatomy by Mr. A. Walker.

Those articles which are connected with History and Antiquities, have been furnished by a distinguished scholar, as will be easily perceived; those relative to the Fine Arts, by a gentleman well known in the literary world; Poetry by a lady, who, like Vida, has asserted her title to the character of a critic, by having excelled in the art itself; the Military articles are the production of a literary gentleman who was educated in that profession; and some of the principal Law articles are by a member of one of the inns of court. Besides these, the editor has been favoured with single communications from Dr. Mavor, Mr. M. Smart, and several correspondents who desire their names to be concealed.

A

DICTIONARY

OF

ARTS AND SCIENCES.

I, the ninth letter of the alphabet, used as a numeral, signifies no more than one, and stands for so many units as it is repeated times: thus, I, one; II, two; III, three, &c. and when put before a higher numeral, it subtracts itself, as IV, four; IX, nine, &c. but when set after it, so many are added to the higher numeral, as there are I's added; thus VI is 5 + 1, or six; VII, 5 + 2, or seven; VIII, 5 + 3, or eight. The antient Romans likewise used IↃ for 500, CIↃ for 1000, IↃↃ for 5000, CCIↃↃ for 10,000, IↃↃↃ for 50,000, and CCCIↃↃↃ for 100,000. Farther than this, as Pliny observes, they did not go in their notation; but when necessary, repeated the last number, as CCCIↃↃↃ, CCCIↃↃↃ for 200,000; CCCIↃↃↃ, CCCIↃↃↃ, CCCIↃↃↃ for 300,000; and so on.

JACK, in mechanics, an instrument in common use for raising heavy timber, or very great weights of any kind, being a powerful combination of teeth and pinions, and the whole inclosed in a strong wooden stock or frame BC, and moved by a winch or handle HP; the outside appearing as in Plate Miscel. fig. 131. In fig. 132, the wheel or rack work is shewn, being the view of the inside when the stock is removed. Though it is not drawn in the just proportions and dimensions, for the rack AB must be supposed at least four times as long in proportion to the wheel Q, as the figure represents it; and the teeth, which will be then four times more in number, to have about three in the inch. Now if the handle HP is seven inches long, the circumference of this radius will be 44 inches, which is the distance or space the power moves through in one revolution of the handle; but as the pinion of the handle has but four leaves, and the wheel Q suppose 20 teeth, or five times the number, therefore to make one revolution of the wheel Q, it requires five turns of the handle, in which case it passes through 5 times 44 or 220 inches; but the wheel having a pinion R of three leaves, these will raise the rack three teeth, or one inch, in the same space. Hence, then, the handle or power moving 220 times as fast as the weight, will raise or balance a weight of 220 times its own energy. And if this is the hand of a man who can sustain 50 pounds weight, he will, by the help of this jack, be able to raise or sustain a weight or force of 11000 pounds, or about five tons weight.

This machine is sometimes open behind from the bottom almost up to the wheel Q, to let the lower claw, which in that case is turned up as at B, draw up any weight. When the weight is drawn or pushed sufficiently high, it is kept from going back by hanging the end of the hook S, fixed to a staple, over the curved part of the handle at h.

The Society of Arts rewarded Mr. Mocock of Southwark, with a premium of 20 guineas, for his contrivance to prevent a jack from taking a retrograde course whenever the weight by any accidental circumstance overbalances the power. The improved jack only differs from those in common use in this respect, that it has a pall or clock, and ratchet, applied in such manner as to stop the motion of the machine as soon as it begins to run back again. As the difference in the mechanism is very trifling, the improvement may be easily applied to any common jacks already made.

Jack is also the name of a well-known engine in the kitchen, used for turning a spit. Here the weight is the power applied, acting by a set of pulleys; the friction of the parts, and the weight with which the spit is charged, are the forces to be overcome; and a steady uniform motion is maintained by means of a fly.

The common worm-jack is represented at Plate Miscel. fig. 130. ABC is the barrel round which the cord QR is wound; KL the main wheel, commonly containing 60 teeth; N the worm-wheel of about thirty teeth, cut obliquely; LM the pinion, of about 15; O the worm or endless screw, consisting of two spiral threads, making an angle of sixty or seventy degrees with its axis; X the stud, and Z the loop of the worm-spindle; P a heavy wheel or fly, connected with the spindle of the endless screw to make the motion uniform; DG the struck wheel fixed to the axis FD; S,S,S, are holes in the frame, by which it may be nailed to a board, and thence to any wall, the end D being permitted to pass through it; HI the handle going upon the axis ET, to wind up the weight when it has run down. R is a box of fixed pulleys, and V a corresponding one of moveable pulleys carrying the weight. The axis ET is fixed in the barrel AC, which axis being hollow, both it and the barrel turn round upon the axis FD, which is fixed to the wheel KL, when it turns in the order BTA; but cannot turn the contrary way, by reason of a catch nailed to the end AB, which lays hold of the cross-bars in the wheel LK.

The weight by means of the cord QR, in consequence of its descent, carries about the barrel AB, which by the action of the catch carries the wheel KL, and this moves the pinion LM and wheel N, the latter moving the worm O and the fly P. Also the wheel LM carries the axis FD with the wheel DG, which carries the cord or chain that goes about the wheel or pulley at the head of the spit. But when the handle H gives motion to the axis in a contrary order to that given by the weight, the catch is depressed; so that although the barrel BC moves and winds the cord upon it, the wheel DG continues at rest. The time which the jack will continue in motion depends upon the number of pulleys at R and V: and as these increase or decrease, so must the weight which communicates the motion, in order to perform the same work in the same time.

Jack, *smoke*, is an engine used for the same purpose as the common jack; and is so called from its being moved by means of the smoke, or rarefied air, ascending the chimney, and striking against the sails of the horizontal wheel AB (Plate Miscel. fig. 129), which being inclined to the horizon, is moved about the axis of the wheel, together with the pinion C, which carries the wheels D and E; and E carries the chain F, which turns the spit. The wheel AB should be placed in the narrow part of the chimney, where the motion of the smoke is swiftest, and where also the greatest part of it must strike upon the sails. The force of this machine depends upon the draught of the chimney, and the strength of the fire.

Smoke-jacks are sometimes moved by means of spiral flyers coiling about a vertical axle; and at other times by a vertical wheel with sails like the float-boards of a mill; but the above is the more customary construction.

JACK-FLAG, in a ship, that hoisted up at the sprit-sail top-mast head.

JACKALL. See CANIS.

JACOB'S STAFF, a mathematical instrument otherwise called cross-staff. See CROSS.

JACOBITES, in church history, a sect of christians in Syria and Mesopotamia; so called either from Jacob, a Syrian, who lived in the reign of the emperor Mauricius; or from one Jacob, a monk, who flourished in the year 550.

JACOBUS, an antient gold coin worth twenty-five shillings.

JACQUINIA, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is decemfid; the stamina inserted into the receptacle; the berry monospermous. There are four species, shrubs of South America.

JADE-STONE, lapis nephriticus, or Jaspachates, a genus of siliceous earths. It gives fire with steel, and is semitransparent like flint. It does not harden in the fire, but melts in the focus of a burning-glass into a transparent green glass with some bubbles. A kind brought from the river of the Amazons in America, and called circoncision stone, melts more easily in the focus into a brown opaque glass, far less hard than the stone itself. The jade-stone is unctuous to the touch; whence Mr. Kirwan seems to suspect, that it contains a portion of argillaceous earth, or rather magnesia. The specific gravity is from 2.970 to 3.389; the texture granular, with a greasy look, but exceedingly hard, being superior in this respect even to quartz itself. It is infusible in the fire, nor can it be dissolved in acids without a particular management; though M. Saussure seems to have extracted iron from it. Sometimes it is met with of a whitish milky colour from China; but mostly of a deep or pale green from America. The common lapis nephriticus is of a grey, yellowish, or olive colour. It has its name from a supposition of its being capable of giving ease in nephritic pains, by being applied externally to the loins. It may be distinguished from all other stones by its hardness, semipellucidity, and specific gravity.

According to Hoepfner it is composed of,

47	silica
38	carbonat of magnesia
9	iron
4	alumina
2	carbonat of lime
100.	

JALAP, *jalapa*, in botany, a plant of the pentandria monogynia class. See CONVOLVULUS, and MATERIA MEDICA.

IAMBIC, in ancient poetry, a sort of verse, so called from its consisting, either wholly or in great part, of iambuses.

IAMBUS, in antient poetry, a simple foot consisting of a short and a long syllable.

JAMES, or *knights of St James*, a military order in Spain, first instituted about the year 1170, by Ferdinand II. king of Leon and Galicia.

JANIZARIES, an order of the Turkish infantry, reputed the grand signior's guards, and the main strength of the Ottoman army.

JANSENISTS, in church-history, a sect of the Roman catholics in France, who follow the opinions of Jansenius, bishop of Ypres, and doctor of divinity of the universities of Louvain and Douay, nearly those of Calvin, in relation to grace and predestination.

JAPANNING is properly the art of varnishing and painting ornaments on wood, in the same manner as is done by the natives of Japan in the East Indies.

The substances which admit of being japanned are almost every kind that are dry and rigid, or not too flexible; as wood, metals, leather, and paper, prepared for the purpose.

Wood and metals do not require any other preparation, but to have their surfaces perfectly even and clean; but leather should be securely strained, either on frames or on boards; as its bending, or forming folds, would otherwise crack and force off the coats of varnish. Paper should be treated in the same manner, and have a previous strong coat of some kind of size; but it is rarely made the subject of japanning till it is converted into papier maché, or wrought by other means into such form, that its original state, particularly with respect to flexibility, is changed.

One principal variation from the method formerly used in japanning is, the omitting any priming, or undercoat, on the work to be japanned. In the older practice, such a priming was always used; the use of which was to save in the quantity of varnish, by filling up the inequalities in the surface of the substance to be varnished. But there is a great inconvenience arising from the use of it, that the Japan coats are constantly liable to be cracked, and peeled off, by any violence, and will not endure near so long as the articles which are japanned without any such priming.

Of the nature of Japan grounds.—When a priming is used, the work should first be prepared by being well smoothed with fish-skin or glass-paper, and being made thoroughly clean, should be brushed over once or twice with hot size, diluted with two-thirds water, if it is of the common strength. The priming should then be laid on as even as possible, and should be formed of a size, of a consistency between the common kind and glue, mixed with as much whiting as will give it a sufficient body of colour to hide the surface of whatever it is laid upon, but not more. This must be repeated till the inequalities are completely filled up, and then the work must be cleaned off with Dutch rushes, and polished with a wet rag.

When wood or leather is to be japanned, and no priming is used, the best preparation is to lay two or three coats of coarse varnish, composed in the following manner.

Take of rectified spirit of wine one pint, and of coarse seed-lac and resin each two ounces; dissolve the seed-lac and resin in the spirit, and then strain off the varnish.

This varnish, as well as all others formed of spirit of wine, must be laid on in a warm place; and if it can be conveniently managed, the piece of work to be varnished should be made warm likewise; and for the same reason, all dampness should be avoided; for either cold or moisture chills this kind of varnish, and prevents its taking proper hold of the substance on which it is laid.

When the work is so prepared, or by the priming with the composition of size and whiting above described, the proper japan ground must be laid on, which is much the best formed of shell-lac varnish, and the colour desired, except white, which requires a peculiar treatment; and if brightness is wanted, then also other means must be pursued.

The colours used with the shell-lac varnish may be any pigments whatever, which give the tint of the ground desired.

As metals never require to be under-coated with whiting, they may be treated in the same manner as wood or leather.

Method of painting Japan work.—Japan work ought properly to be painted with colours in varnish; though, for the greater dispatch, and in some very nice work in small, for the freer use of the pencil, the colours are sometimes tempered in oil; which should previously have a fourth part of its weight of gum animi dissolved in it; or in default of that, gum sandarach, or gum mastich. When the oil is thus used, it should be well diluted with oil of turpentine, that the colours may lie more evenly and thin; by which means fewer of the polishing or upper coats of varnish become necessary.

In some instances, water-colours are laid on grounds of gold, in the manner of other paintings; and are best, when so used in their proper appearance, without any varnish over them; and they are also sometimes so managed as to have the effect of embossed work. The colours employed in this way, for painting, are best prepared by means of isinglass size, corrected by honey or sugar-candy. The body, of which the embossed work is raised, need not, however, be tinged with the exterior colour, but may be best formed of very strong gum-water, thickened to a proper consistence by bole armenian and whiting in equal parts; which being laid on the proper figure, and repaired when dry, may be then painted with the proper colours, tempered with the isinglass size, or, in the usual manner, with shell-lac varnish.

Manner of varnishing japan work.—The finishing of japan-work depends on the laying on, and polishing, the outer coats of varnish which are necessary, as well in the pieces that have only one simple ground of colour, as with those that are painted. This is in general done best with common seed-lac varnish, except in the instances, and on those occasions, where particular methods are deemed to be more expedient; and the same reasons which decide as to the fitness or impropriety of the varnishes, with respect to the colours of the ground, hold equally with regard to those of the painting. For where brightness is the most material point, and a tinge of yellow will injure it, seed-lac must give way to the whiter gums; but where hardness and a greater tenacity are most essential, it must be adhered to; and where both are so necessary, that it is proper one should give way to the other in a certain degree reciprocally, a mixed varnish must be adopted.

This mixed varnish, as we have already observed, should be made of the picked seed-lac. The common seed-lac varnish, which is the most useful preparation of the kind hitherto invented, may be thus made.

Take of seed-lac three ounces, and put it into water, to free it from the sticks and filth that are frequently intermixed with it; and which must be done by stirring it about, and then pouring off the water, and adding fresh quantities, in order to repeat the operation, till it is freed from all impurities, as is very effectually done by this means. Dry it then, and powder it grossly, and put it, with a pint of rectified spirit of wine, into a bottle, of which it will not fill above two-thirds. Shake the mixture well together, and place the bottle in a gentle heat, till the seed-lac appears to be dissolved; the shaking being in the mean time repeated as often as may be convenient; and then pour off all that can be obtained clear by this method, and strain the remainder through a coarse cloth. The varnish thus prepared, must be kept for use in a bottle well stopped.

When the spirit of wine is very strong, it will dissolve a greater proportion of the seed-lac; but this quantity will saturate the common, which is seldom of a strength sufficient to make varnishes in perfection. As the chilling, which is the most inconvenient accident attending varnishes of this kind, is prevented or produced more frequently, according to the strength of the spirit; we shall therefore take this opportunity of shewing a method by which weaker rectified spirits may with great ease at any time be freed from the phlegm, and rendered of the first degree of strength.

Take a pint of the common rectified spirit of wine, and put it into a bottle, of which it will not fill above three parts; add to it half an ounce of pearl-ashes, salt of tartar, or any other alkaline salt, heated red-hot, and powdered as well as it can be without much loss of its heat. Shake the mixture frequently for the space of half an hour; before which time, a great part of the phlegm will be separated from the spirit, and will appear, together with the undissolved part of the salts, in the bottom of the bottle. Let the spirit be poured off, or freed from the phlegm and the salts, by means of a tritorium, or separating funnel; and let half an ounce of the pearl-ashes, heated and powdered as before, be added to it, and the same treatment repeated. This may be done a third time, if the quantity of phlegm separated by the addition of the pearl-ashes appears considerable. An ounce of alum reduced to powder, and made hot, but not burnt, must then be put into the spirit, and suffered to remain some hours, the bottle being frequently shaken; after which the spirit, being poured off from it, will be fit for use.

The addition of the alum is necessary to neutralize the remains of the alkaline salt, which would otherwise greatly deprave the spirit, with respect to varnishes and lacquer where vegetable colours are concerned, and must consequently render another distillation necessary.

The manner of using the seed-lac, or white varnish, is the same, except with regard to the substance used in polishing: which, where a pure white of a great clearness of other colours is in question, should be itself white; whereas the browner sorts of polishing-dust, as being cheaper, and doing their business with greater dispatch, may be used in other cases. The pieces of work to be varnished, should be placed near a fire, or in a room where there is a stove, and made perfectly dry; and then the varnish may be rubbed over them by the proper brushes made for that purpose, beginning in the middle, and passing the brush to one end, and then with another stroke from the middle, passing it to the other. But no part should be crossed, or twice passed over, in forming one coat, where it can be possibly avoided. When one coat is dry, another must be laid over it; and this must be continued at least five or six times, or more, if on trial, there is not sufficient thickness of varnish to bear the polish, without laying bare the painting or ground-colour underneath.

When a sufficient number of coats is thus laid on, the work is fit to be polished; which must be done, in common cases, by rubbing it with a rag dipped in tripoli, or rottenstone, finely powdered; but, towards the end of the rubbing, a little oil of any kind should be used along with the powder; and when the work appears sufficiently bright and glossy, it should be well rubbed with the oil alone, to clean it from the powder, and give it a still brighter lustre.

JARGON. See ZIRCON.

JASIONE, a genus of the monogamia order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, campanaceæ. The common calyx is ten-leaved; and the corolla has five regular petals; the capsule beneath, two-celled. There are four species, shrubs of the West Indies.

JASMINUM, JASMINE, or JESSAMINE-TREE, a genus of the monogynia order, in the diandria class of plants, and in the natural method ranking under the 44th order, sepiariæ. The corolla is salver-shaped, the berry dicoccous; the seeds arillated, the antheræ within the tube. There are 17 species. The most remarkable are: 1. The officinalis, or common white jasmine, with shrubby long slender stalks and branches, rising upon supports 15 or 20 feet high, with numerous white flowers from the joints and ends, of a very fragrant odour. There is a variety with white-striped, and another with yellow-striped leaves. 2. The fruticans, or shrubby yellow jasmine, has shrubby, angular, trailing stalks and branches, rising upon support eight or ten feet high; trifoliate and simple alternate leaves; with yellow flowers from the sides and ends of the branches, appearing in June; frequently producing berries of a black colour. This species is remarkable for sending up many suckers from its roots, often so plentifully as to overspread the ground, if not taken up annually. 3. The humilis, or dwarf yellow jasmine, has shrubby firm stalks, and angular branches, of low, somewhat robust and bushy growth; broad, trifoliate, and pinnated leaves; and large yellow flowers in July, sometimes succeeded by berries. 4. The grandiflorum, or great-flowered Catalonian jasmine, has a shrubby, firm, upright stem, branching out into a spreading head from about three to six or eight feet high, with large flowers of a blueish-red colour without, and white within, appearing from July to November. Of this there is a variety with semidouble flowers, having two series of petals. 5. The azoricum, or azorian white jasmine, has shrubby, long, slender stalks and branches, rising upon supports 15 or 20 feet high, with pretty large flowers of a pure white colour, coming out in loose bunches from the ends of the branches, and appearing most part of the summer and autumn. 6. The odoratissimum, or most sweet-scented yellow Indian jasmine, has a shrubby upright stalk branching erect, without support, six or eight feet high, with bright yellow flowers in bunches, from the ends of the branches; flowering from July till October, and emitting a most fragrant odour.

The first three species are sufficiently hardy to thrive in this climate without any shelter. The other three species, which are tender, may be increased by layers or seeds, or by grafting and budding them upon the common white and shrubby yellow jasmine. They require shelter in a greenhouse in winter, and therefore must always be kept in pots to move them out and in occasionally.

JASPER. This stone is an ingredient in the composition of many mountains. It occurs usually in large amorphous masses, sometimes in rounded or angular pieces. Its fracture is conchoidal. Specific gravity from 2.3 to 2.7. Its colours are various. When heated, it does not decrepitate. It is usually divided into 4 subspecies.

1. *Egyptian pebble.* This variety is found chiefly in Egypt. It usually has a spheroidal or flat-rounded figure, and is enveloped in a coarse rough crust. Specific gravity 2.564 to 2.6. It is chiefly distinguished by the variety of colours which always exist in the same specimen, in concentric stripes or layers. These colours are different browns and yellows, greens, &c.

2. *Striped jasper.* This variety is also distinguished by concentric stripes or layers of different colours: these colours are yellow, brownish-red, and green. It is distinguished from the last variety by its occurring in large amorphous masses, and by the disposition of its stripes.

3. *Porcelain jasper.* So called because its fracture presents the appearance of porcelain. Its colours are various shades of grey, yellow, red, brown, green, mixed together. Found in mass, and in rounded pieces. Greasy. Fracture imperfectly conchoidal: opaque: brittle. According to Rose it is composed of

60.75	silica
27.25	alumina
3.00	magnesia
2.50	oxide of iron
3.60	potass
97.10	

Found in the neighbourhood of pseudo volcanoes, supposed to have been altered by the action of fire.

4. *Common jasper.* Specific gravity from 2.53 to 2.7. Its colours are different shades of white, yellow, red, brown, and green; often variegated, spotted, or veined, with several colours.

JATROPHA, the *cassada plant*, a genus of the monadelphia order, in the monœcia class of plants, and in the natural method ranking under the 38th order, tricocca. There is no male calyx; the corolla is monopetalous, and funnel-shaped; there are ten stamina, one alternately longer than the other. There is no female calyx; the corolla is pentapetalous and patent; there are three bifid styles; the capsule is trilocular, with one seed in each cell. There are nine species, of which the most remarkable are: 1. The curcas, or English physic-nut, with leaves cordate and angular, is a knotty shrub growing about 10 or 12 feet high. The extremities of the branches are covered with leaves; and the flowers, which are of a green herbaceous kind, are set on in an umbel fashion round the extremities of the branches, but especially the main stalks. These are succeeded by as many nuts, whose outward tegument is green and husky, which being peeled off discovers the nut, whose shell is black, and easily cracked; this contains an almond-like kernel, divided into two parts, betweed which separation lie two milk-white thin membranaceous leaves, easily separable from each other. These have not only a bare resemblance of perfect leaves, but have in particular every part, the stalk, the middle rib, and transverse ones, as visible as any leaf whatsoever. 2. The gossypifolia, cotton-leaved jatropha, or belly-ache bush, the leaves of which are quinquepartite, with lobes ovate and entire, and glandular branchy bristles. The stem, which is covered with a light-greyish bark, grows to about three or four feet high, soon dividing into several wide-extended branches. From among these rise several small deep-red pentapetalous flowers, the pistil of each being thick-set at the top with yellow farinaceous dust, which blows off when ripe. These flowers are succeeded by hexagonal husky blackish berries, which, when ripe, open by the heat of the sun, emitting a great many small dark-coloured seeds, which serve as food for ground doves. 3. The multifida, or French physic-nut, with leaves many-parted and polished. The flowers of this grow in bunches, umbel fashion, upon the extremities of each large stalk, very much resembling, at their first appearance, a bunch of red coral: these afterwards open into small five-leaved purple flowers, and are succeeded by nuts, which resemble those of the first species. 4. The manihot, or bitter cassada, has palmated leaves; the lobes lanceolate, very entire, and polished. 5. The janipha, or sweet cassada, has palmated leaves, with lobes very entire; the intermediate leaves lobed with a sinus on both sides. 6. The elastica, with ternate leaves, elliptic, very entire, hoary underneath, and longly petioled. See figures of the two last in plate 22, which renders a more particular description unnecessary.

The root of bitter cassada has no fibrous or woody filaments in the heart, and neither boils nor roasts soft. The sweet cassada has all the opposite qualities. The bitter, however, may be deprived of its noxious qualities (which reside in the juice) by heat. Cassada bread, therefore, is made of both the bitter and sweet, thus: the roots are washed and scraped clean, then grated into a tub or trough; after this they are put into a hair bag, and strongly pressed with a view to squeeze out the juice, and the meal or farina is dried in a hot stone bason over the fire; it is then made into cakes. It also makes excellent puddings, equal to millet. The scrapings of fresh bitter cassada are successfully applied to ill-disposed ulcers. Cassada roots yield a great quantity of starch, which the Brasilians export in little lumps under the name of tapioca. According to father Labat, the smallest bits of manioc which have escaped the grater, and the clods which have not passed the sieve, are not useless. They are dried in the stove after the flour is roasted, and then pounded in a mortar to a fine white powder, with which they make soup. It is likewise used for making a kind of thick coarse cassada, which is roasted till almost burnt; of this, fermented with melasses and West India potatoes, they prepare a much esteemed drink or beverage called ouycou. This liquor, the favourite drink of the natives, is sometimes made extremely strong, especially on any great occasion, as a feast: with this they get intoxicated, and remembering their old quarrels, massacre and murder each other. Such of the inhabitants and workmen as have not wine, drink ouycou. It is of a red colour, strong, nourishing, refreshing, and easily inebriates the inhabitants, who soon accustom themselves to it as easily as beer.

The 6th species is the hevea guianensis of Aublet, or tree which yields the elastic resin called caoutchouc, or India rubber: for a particular account of which see CAOUTCHOUC. The figure we have given is copied from Aublet's tab. 335, and not from the erroneous plate given in the Acta Parisiana.

JAU-RAIA. See RAJANIA.

JAUNDICE. See MEDICINE.

JAW. See ANATOMY.

IBERIS, *sciatica cresses*, or *candy-tuft*, a genus of the siliquosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The corolla is regular; the two exterior petals larger than the interior ones; the silicula polyspermous, emarginated. There are 14 species. The most remarkable are: 1. The umbellata, or common candy-tuft, a well-known annual. 2. The amara, or bitter candy-tuft. 3. The sempervirens, commonly called tree candy-tuft. 4. The semperflorens, with white flowers in umbels at the ends of the branches, appearing at all times of the year.

IBEX, in zoology. See CAPRA.

IBIS. See TANTALUS.

ICE. See WATER, and COLD.

ICE-HOUSE, a building contrived to preserve ice for the use of a family in the summer season. It is generally sunk some feet in the ground in a very shady situation, and covered with thatch.

ICELAND-AGATE, a precious stone met with in the islands of Iceland and Ascension, employed by the jewellers as an agate, though too soft for the purpose. It is supposed to be a volcanic product; being solid, black, and of a glassy texture. When held between the eye and the light, it is semitransparent, and greenish, like the glass bottles which contain much iron. In the islands which produce it, such large pieces are met with that they cannot be equalled in any glass-house.

ICHNEUMON *fly*, the name of a genus of flies of the hymenoptera order. The generic character is, mouth with jaws, without tongue; antennæ with more than thirty joints; abdomen in most species footstalked; piercer exserted, with a cylindric bivalve sheath. The animals of this genus provide for the support of their offspring in a manner highly extraordinary, depositing their eggs in the bodies of other living insects, and generally in those of caterpillars. These eggs in a few days hatch, and the young larvæ, which resemble minute white maggots, nourish themselves with the juices of the unfortunate animal, which however continues to move about and feed till near the time of its change to a chrysalis, when the young brood of ichneumon-larvæ creep out by perforating the skin in various places, and each spinning itself up in a small oval silken case, changes into a chrysalis, the whole number forming a groupe on the shrivelled body of the caterpillar which had afforded them nourishment; and after a certain period emerge in the state of complete ichneumons.

It was the want of an exact knowledge of the genus ichneumon that proved so considerable an embarrassment to the older entomologists, who having seen a brood of ichneumons proceed from the chrysalis of a butterfly, could not but conclude that the production of insects was rather a variable and uncertain operation of nature than a regular continuation of the same species. The observations however of Swammerdam, Malphigi, Roesel, and others, have long since removed the difficulties which formerly obscured the history of the insect tribe. See Plate Nat. Hist. figs. 232, 233. It is said there are no less than 415 species of this insect.

ICHNOGRAPHY, in perspective, the view of any thing cut off by a plane parallel to the horizon, just at the base of it. Among painters it signifies a description of images, or of antient statues of marble and copper, of busts and semi-busts, of paintings in fresco, mosaic works, and antient pieces of miniature.

ICHNOGRAPHY. See ARCHITECTURE.

ICHTHYOCOLLA. See ACCIPENSER, and GELATINA.

ICHTHYOLITHUS, in natural history, the body or parts of a fish changed into a fossil substance. Four species are enumerated. The niger is found in a black slate in the island of Sheppey, and various parts of Wales, in the mountains of Switzerland, Silesia, Germany, &c. impregnated with bitumen, pyritaceous matter, or oxide of copper. The fishes resemble the eel, swordfish, cod, flat fish, perch, roach, dace, mackrel, mullet, carp, &c. The albidus is found in various parts of England, on mount Libanus in Palestine, in the ecclesiastical territories of Italy, in Switzerland, Bavaria, &c. The fishes are rarely of the sea kind, but usually those that inhabit the fresh water. They are seldom found whole, but in different parts, as the head, gill-covers, and other bones, fins, tails, tendrils, or scales, in a grey slaty swinestone, or impressed on shistose marble, and sometimes penetrated with bitumen.

ICHTHYOLOGY, ιχθυολογια, the science of fishes, or that branch of zoology which treats of fishes. See FISH, and COMPARATIVE ANATOMY.

ICONOCLASTS, in church history, an appellation given to those persons who in the eighth century opposed image-worship, and still given by the church of Rome to all christians who reject the use of images in religious matters.

ICOSAHEDRON, in geometry, a regular solid, consisting of 20 triangular pyramids, whose vertices meet in the centre of a sphere, supposed to circumscribe it, and therefore have their height and bases equal; wherefore the solidity of one of those pyramids multiplied by 20, the number of bases, gives the solid content of the icosahedron.

If fig. 127, Plate Miscel. be nicely drawn on pasteboard, cut half through, and then folded up neatly together, it will represent an icosahedron. See fig. 128.

To form an icosahedron, describe upon card paper 20 equilateral triangles; cut it out by the extreme edges, and cut all the other lines half-through; then fold up by these edges, and the solid will be formed. The linear edge of the icosahedron being A, then the surface will be $5A^2\sqrt{3} = 8.660\ A^2$, and the solidity $\frac{5}{6}\ A^3\ \sqrt{\frac{7+3\sqrt{5}}{2}} = 2.1817\ A^3$.

ICOSANDRIA, from εικοσι "twenty," and ανηρ, "a man or husband;" the name of the 12th class in Linnæus's sexual method, consisting of plants with hermaphrodite flowers, which are furnished with 20 or more stamina, that are inserted into the inner side of the calyx or petals. See Botany.

IDES, *idus*, in the antient Roman calendar, were eight days in each month, the first of which fell on the 15th of March, May, July, and October, and on the 13th day of other months. They were reckoned backwards: thus they called the 14th day of March, May, July, and October, and the 12th of the other months, the pridie idus, or the day before the ides; the next preceding day, they called the tertio idus; and so on, reckoning always backwards, till they came to the nones. This method of reckoning time is still retained in the chancery of Rome, and in the calendar of the breviary.

IDIOT, is a fool or madman from his nativity. By the old common law there is a writ de idiota inquirendo, directed to the sheriff, to inquire by a jury whether the party is an idiot or not; and if they find him a perfect idiot, the profits of his lands and the custody of his person belong to the king, according to the stat. 17 Ed. II. c. 9. by which it is enacted, that the king shall have the custody of the lands of natural fools, taking the profits of them without waste or destruction, and shall find them necessaries, of whose fee soever the land shall be holden. And after the death of such idiots, he shall render it to the right heir, so that such idiots shall not alien, nor their heirs be disinherited. But it seldom happens that a jury finds a man an idiot from his nativity, but only non compos mentis from some particular time, which has an operation very different in point of law; for in this case he comes under the denomination of a lunatic, in which respect the king shall not have the profits of his lands, but is accountable for the same to the lunatic when he comes to his right mind, or otherwise to his executors or administrators. 1 Black. 303.

JEER, or Jeer-rope, in a ship, is a large rope reeved through double or treble blocks, lashed at the mast-head, and on the yard, in order to hoist or lower the yards.

JEJUNUM. See Anatomy.

JELLY, in chemistry. If we press out the juice of ripe blackberries, currants, and many other fruits, and allow it to remain for some time in a state of rest, it partly coagulates into a tremulous soft substance, well known by the name of jelly. If we pour off the uncoagulated parts, and wash the coagulum with a small quantity of water, we obtain jelly approaching to a state of purity.

In this state it is nearly colourless, unless tinged by the peculiar colouring matter of the fruit; it has a pleasant taste, and a tremulous consistency. It is scarcely soluble in cold water, but very soluble in hot water; and when the solution cools, it again coagulates into the form of a jelly. When long boiled, it loses the property of gelatinizing by cooling, and becomes analogous to mucilage. This is the reason that in making currant-jelly, or any other jelly, when the quantity of sugar added is not sufficient to absorb all the watery parts of the fruit, and consequently it is necessary to concentrate the liquid by long boiling, the mixture often loses the property of coagulating, and the jelly, of course, is spoiled.

Jelly combines readily with alkalies. Nitric acid converts it into oxalic acid, without separating any azotic gas. When dried it becomes transparent. When distilled it affords a great deal of pyromucous acid, a small quantity of oil, and scarcely any ammonia.

Jelly exists in all acid fruits, as oranges, lemons, gooseberries, &c. If the juice of these fruits is allowed to gelatinize, and then poured upon a searce, the acid gradually filtres through, and leaves the other; which may be washed with a little cold water, and allowed to dry. Its bulk gradually diminishes, and it concretes into a hard transparent brittle mass, which possesses most of the properties of gum. Perhaps, then, jelly is merely gum combined with vegetable acid.

Jelly, *animal*. See Gelatine.

JESUITS, or the society of Jesus, a most famous religious order in the Romish church, founded by Ignatius Loyola, a native of Guipuscoa in Spain, who in the year 1738 assembled ten of his companions at Rome, principally chosen out of the university of Paris, and made a proposal to them to form a new order; when, after many deliberations, it was agreed to add to the three ordinary vows of chastity, poverty, and obedience, a fourth, which was, to go into all countries whither the pope should please to send them, in order to make converts to the Romish church. Two years after, pope Paul III. gave them a bull, by which he approved this new order, giving them a power to make such statutes as they should judge convenient; on which, Ignatius was created general of the order, which in a short time spread over all the countries of the world, to which Ignatius sent his companions, while he staid at Rome, whence he governed the whole society. The order was abolished by pope Clement XIV. (Ganganelli) in 1773. See Gregory's Church History, vol. ii.

Jesuit's-*bark*. See Cinchona, and Pharmacy.

JET. See Coal.

Jet d'eau. See Hydraulics.

JETSON, Jetsen, or Jetsam, in law, is used for any thing thrown out of a ship or vessel that is in danger of being a wreck, and which is driven by the waves on shore.

JEWS. In England in former times, the Jews and all their goods belonged to the chief lord where they lived. By stat. Ed. I. the Jews, to the number of 15,000, were banished out of England, and never returned till Oliver Cromwell readmitted them.

Whenever any Jew shall present himself to take the oath of abjuration, in pursuance of the 10 Geo. III. c. 10. the words, upon the true faith of a christian, shall be omitted out of the said oath in administering it to such persons; and the taking the said oath by persons professing the Jewish religion, without the said words, in like manner as Jews are admitted to give evidence in courts of justice, shall be deemed a sufficient taking of it.

IGNATIA, a genus of the monogynia order, in the pentandria class of plants. The calyx is five-toothed; the corolla is long; the fruit an unilocular plum, with many seeds. There are two species, the principal of which is the amara, a native of India. The fruit of this tree contains the seeds called St. Ignatius's beans. According to some, it is from this plant that the columbo root is obtained.

IGNIS Fatuus, a common meteor, chiefly seen in dark nights about meadows, marshes, and other moist places, as also in burying-grounds, and near dung-hills. It is known among the people by the appellations, Will with a wisp, and Jack with a lantern. See Meteors.

IGNITION. See Caloric, and Chemistry.

IGNORAMUS, was formerly indorsed by the grand jury on the back of a bill, for which they did not find sufficient evidence; but now, since the proceedings were in English, they indorse "no bill," or "not a true bill," or which is the better way, "not found." 4 305.

IGUANA. See Lacerta.

JIB, the foremost sail of a ship, being a large stay-sail extended from the outer end of the bowsprit prolonged by the jib-boom, towards the fore-top-mast-head. See Sail.

Jib-*boom*, a boom run out from the extremity of the bowsprit, parallel to its length, and serving to extend the bottom of the jib, and the stay of the fore-top-gallant-mast.

ILEX, *the holm or holly tree*, a genus of the tetragynia order, in the tetrandria class of plants, and in the natural method ranking under the 43d order, dumosæ. The calyx is quadridentated; the corolla rotaceous; there is no style; the berry is monospermous. There are 16 species of this genus; but the most remarkable is the aquifolium, or common holly. Of this there are a great number of varieties with variegated leaves, which are propagated by the nursery gardeners for sale. The best of these varieties are the painted-lady holly, British holly, Bradley's best holly, phyllis or cream holly, milkmaid holly, Pritchet's best holly, gold-edged hedgehog holly, Chyney's holly, glory-of-the-west holly, Broaderick's holly, Partridge's holly, Herefordshire white holly, Blind's cream holly, Longstaff's holly, Eales's holly, silver-edged hedgehog holly. All these varieties are propagated by budding or grafting them upon stocks of the common green holly.

Sheep in the winter are fed with croppings of holly. Birds eat the berries. The bark fermented, and afterwards washed from the woody fibres, makes the common birdlime. The plant makes an impenetrable fence, and bears cropping; however, it is not found in all respects to answer for this purpose equally well with the hawthorn. The wood is used in fineering, and is sometimes stained black to imitate ebony. Handles for knives, and cogs for mill-wheels, are made of it. Mr. Miller says, he has seen the floor of a room laid with compartments of holly and mahogany, which had a very pretty effect.

ILIAC PASSION. See MEDICINE.

ILLECEBRUM, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. The calyx is pentaphyllous, and cartilaginous; there is no corolla; the stigma is simple; the capsule quinquevalved, and monospermous. There are 21 species, of which the most remarkable are the paronychia and the capitatum. Both these have trailing stalks near two feet long, which spread on the ground, furnished with small leaves like those of knot-grass. The heads of the flowers come out from the joints of the stalks, having neat silvery bracteæ surrounding them, which make a pretty appearance. Their flowers appear in June, and there is generally a succession of them for at least two months; and when the autumn proves warm, they will ripen their seeds in October.

ILLICIUM, a genus of the pentagynia order, in the dodecandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is tetraphyllous, and deciduous; there are eight petals, and eight petaloid subulated nectaria. There are 16 stamina with bifid antheræ; the capsules are ovate, compressed, and monospermous. There are two species, viz. 1. The floridanum, with red flowers, and very odorous fruit. It is a native of China. 2. The anisatum, a native of the woods of China and Japan. The first is a very ornamental plant, and now common in our greenhouses.

ILLUMINATING, a kind of miniature-painting, antiently much practised for illustrating and adorning books. Besides the writers of books, there were artists whose profession was to ornament and paint manuscripts, who were called illuminators: the writers of books first finished their part, and the illuminators embellished them with ornamented letters and paintings. We frequently find blanks left in manuscripts for the illuminators, which were never filled up. Some of the antient manuscripts are gilt and burnished in a style superior to later times. Their colours were excellent, and their skill in preparing them must have been very great.

IMAM, a name applied by the Mahometans to him who is head of the congregation in their mosques; and by way of eminence to him who has the supreme authority both in respect to spirituals and temporals.

IMBEZLE, signifies to steal, pilfer, or purloin, and also to waste or diminish goods, &c. entrusted to a person's charge and care. Imbezlers of wool forfeit double damages, and may be committed to the house of correction till paid; and servants imbezling their masters' goods to the value of 40*s*. are deemed guilty of felony without benefit of clergy.

IMBRICATED, among botanists, an appellation given to such leaves of plants, as are placed over one another like the tiles of a house. The term is likewise applied to some of the heart-shells, from their being ridged transversely in the same manner.

IMMEMORIAL, in a legal sense, a thing is said to be of time immemorial, or time out of mind, that was before the reign of king Edward II.

IMMERSION, in astronomy, is when a star or planet is so near the sun with regard to our observations, that we cannot see it; being enveloped and hid in the rays of that luminary. It also denotes the beginning of an eclipse of the moon, or that moment when the moon begins to be darkened, and to enter into the shadow of the earth; and the same term is also used with regard to an eclipse of the sun, when the disk of the moon begins to cover it. In this sense emersion stands opposed to immersion, and signifies the moment wherein the moon begins to come out of the shadow of the earth, or the sun begins to shew the parts of his disk which were hid before. Immersion is frequently applied to the satellites of Jupiter, and especially to the first satellite; the observation of which is of so much use for discovering the longitude. The immersion of that satellite is the moment in which it appears to enter within the disk of Jupiter, and its emersion the moment when it appears to come out. The immersions are observed from the time of the conjunction of Jupiter with the sun, to the time of his opposition; and the emersions from the time of his opposition to his conjunction.

IMPALED, in heraldry: when the coats of a man and his wife who is not an heiress are borne in the same escutcheon, they must be marshalled in pale; the husband's on the right side, and the wife's on the left: and this the heralds call baron and feme, two coats impaled. See HERALDRY.

IMPARLANCE, in law, a petition in court for a day to consider or advise what answer the defendant shall make to the plaintiff's action, and is the continuance of the cause till another day, or a longer time given by the court.

An imparlance is general or special; general is when it is entered in general terms, without any special clause therein; special is where the defendant desires a further day to answer. And this last imparlance is of use to plead some matters, which cannot be pleaded after a general imparlance.

It is said that imparlance was formerly from day to day, but now it is from one term to another. In case the plaintiff amends his declaration after the same is delivered or filed, the defendant may in course impارl to the next term afterwards, unless the plaintiff pays costs; but if he does, and they are accepted, the defendant may not have an imparlance. Likewise the not delivering a declaration in time is sometimes the cause of imparlance; and when the plaintiff declares, yet does not proceed in three terms after, in such case the defendant may imparl to the next succeeding term. But there are divers cases wherein imparlances are not to be given: as where a person is sued by an attorney or any other privileged person of the court, in an assize, one may not imparl, except good cause be given; nor shall there be imparlance in action of special clausum fregit, &c.

IMPATIENS, the common balsam, or noli me tangere, a genus of the class and order syngenesia monogamia. The calyx is two-leaved; corolla five-petalled, irregular, with a cowled nectarium; capsule superior, five-valved. There are 12 species, all annuals. The noli me tangere is indigenous to Britain, and has its specific name from the capsule shooting forth its seeds to a great distance when touched.

IMPEACHMENT, is the accusation and prosecution of a person in parliament, for treason or other crime and misdemeanor. An impeachment before the lords by the commons of Great Britain, is a presentment to the most high and supreme court of criminal jurisdiction, by the most solemn, grand inquest of the whole kingdom. A commoner cannot be impeached before the lords for any capital offence, but only for high misdemeanors; but a peer may be impeached for any crime. The articles of impeachment are a kind of bill of indictment, found by the house of commons, and afterwards tried by the lords, who are in cases of misdemeanors considered not only as their own peers, but as the peers of the whole nation. By stat. 12 and 13 W. c. 2. no pardon under the great seal shall be pleadable to an impeachment by the commons in parliament. 4 Black. 259.

In the case of Warren Hastings, in the year 1791, it was solemnly determined that impeachments do not abate by a dissolution of parliament.

IMPEACHMENT *of waste*, signifies a restraint from committing of waste upon lands and tenements; and therefore he that has a lease without impeachment of waste, has by that a property or interest given him in the houses and trees, and may make waste in them without being impeached for it, that is, without being questioned or demanded any recompence for the waste done. 11 Rep. 82.

IMPEDIMENTS IN LAW. Persons under impediments are those within age, under coverture, non compos mentis, in prison, or beyond seas, who, by a saving in our laws, have time to claim and prosecute the right, after the impediments removed, in case of fines levied, &c.

IMPERATIVE, one of the moods of a verb, used when we would command, entreat, or advise.

IMPERATORIA, *masterwort*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The fruit is roundish, compressed in the middle, gibbous, and surrounded with a border; the petals are inflexo-emarginated. There is but one species, viz. the ostruthium, a native of the Austrian and Stythian Alps, and other mountainous places of Italy. The plant is cultivated in gardens for the sake of its roots, which are used in medicine. The root has a flavour similar to that of angelica, and is esteemed a good sudorific. There are instances of its having cured the ague when the bark had failed. It should be dug up in winter, and a strong infusion made in wine.

IMPERFECT, something that is defective, or that wants some of the properties found in other beings of the same kind: thus mosses are called imperfect plants, because almost all the parts of fructification are wanting in them; and for the like reason is the appellation imperfect given to the fungi and submarine plants. See MOSS, FUNGI, and SUBMARINE.

Imperfect flowers, those otherwise called stamineous.

Imperfect numbers, such whose aliquot parts, taken together, do either exceed or fall short of that whole number of which they are parts: they are either abundant or deficient.

IMPERSONAL verb, in grammar, a verb to which the nominative of any certain person cannot be prefixed; or, as others define it, a verb destitute of the two first and primary persons.

IMPETUS, in mechanics, the force with which one body impels or strikes another.

IMPLICATION, is where the law implies something that is not declared by parties in their deeds and agreements; and when our law gives any thing to a man, it gives implicitly whatsoever is necessary for enjoying the same. 4 Black. 200.

An implied contract is such, where the terms of agreement are not expressly set forth in words, but are such as reason and justice dictate, and which therefore the law presumes that every man undertakes to perform. Id.

An implication cannot be intended by deed, unless there are apt words, but otherwise in a will. Brownl. 153.

IMPORTATION, the act of bringing goods into a country from foreign parts. It has generally been considered, that for any country to carry on a profitable trade, it is necessary that the value of the goods sent out of it should be greater than that of the articles imported: this, however, is a very erroneous axiom, unless it is understood with great limitations. All articles of merchandize, imported merely for re-exportation, and also such as are used or worked up in our own manufactures, are far from being hurtful to our commerce; and may even, in many respects, be deemed of equal profit with our own native commodities. It is therefore an excess of such importations alone as are either for mere luxury or mere necessity, or for both together, which is disadvantageous to the country, and not such importations as, like many of ours, consist of raw silk, Spanish wool, cotton wool and yarn, mohair, flax and hemp, oils, potasses, dyeing stuffs, naval stores, &c. either used in our ship-building, or worked up in our manufactures, a principal part of which are for exportation: neither can our importations of East India goods and colonial produce, which are chiefly designed to be afterwards exported, be deemed unprofitable, but are, on the contrary, some of the most lucrative branches of our foreign trade.

The following statement of the total value of the imports of England, in the year 1354, furnishes a curious comparison with their present magnitude.

	£.	s.	d.
1831 fine cloths, at 6*l*. per cloth, which, with the customs, come to - -	11,083	12	0
397¾ hundred weight of wax, at 40*s*. per hundred weight, which, with the customs, come to - -	815	7	5
1829½ tons of wine, at 40*s*. per ton, which, with the customs, come to - -	3,841	19	0
Linen-cloth, mercery, grocery, and all other wares -	22,943	6	10
On which the customs were	285	18	3
Total -	38,970	3	6

At this period, and for a long time after, foreigners were the principal importers of goods in this country; and as it was thought that many of them, after disposing of their merchandise here, returned with the value in money to their own country, which was deemed a serious injury, many laws were made against carrying out of the realm any gold or silver, either in coin, plate, or bullion; and merchant strangers were compelled to give security that they would lay out all the money they received for the wares they imported, in English merchandize to be exported. These injudicious restrictions have been long since done away; and excepting the prohibition of some foreign manufactures, the import trade of this country is probably as free as the regulations necessary to secure the payment of heavy duties on almost every article of trade will admit.

Total official value of the imports of Great Britain in the year 1800.

Port of London -	£18,843,172	2	10
The outports -	9,514,642	11	10
England - -	28,357,814	14	8
Scotland - -	2,212,790	11	8
	30,570,605	6	4

	East Indies and China.	All other parts.
In 1801	£5,424,441	£27,371,115
1802	5,794,906	25,647,412
1803	6,348,887	21,643,577
1804	5,214,621	23,986,869
1805		24,273,451

The official value of the imports of Ireland in the year 1805, was 5,982,194*l*. 19*s*. 9*d*.

IMPOSSIBLE roots, in algebra. To discover how many impossible roots are contained in any proposed equation, sir I. Newton gave this rule, in his Algebra, viz.: Constitute a series of fractions, whose denominators are the series of natural numbers 1, 2, 3, 4, 5, &c. continued to the number shewing the index or exponent of the highest term of the equations, and their numerators the same series of numbers in the contrary order; and divide each of these fractions by that next before it, and place the resulting quotients over the intermediate terms of the equation; then under each of the intermediate terms, if its square multiplied by the fraction over it, be greater than the product of the terms on each side of it, place the sign +; but if not, the sign —; and under the first and last term place the sign +. Then will the equation have as many imaginary roots as there are changes of the underwritten signs from + to —, and from — to +. So for the equation $x^3 - 4x^2 + 4x - 6 = 0$, the series of fractions is $\frac{3}{1}, \frac{2}{2}, \frac{1}{3}$; then the second divided by the first gives $\frac{2}{6}$ or $\frac{1}{3}$, and the third divided by the second gives $\frac{1}{3}$ also; hence these quotients placed over the intermediate terms, the whole will stand thus,

$$\begin{array}{cccc} & \frac{1}{3} & \frac{1}{3} & \\ x^3 & - 4x^2 & + 4x & - 6. \\ + & + & - & + \end{array}$$

Now because the square of the second term multiplied by its superscribed fraction, is $\frac{16}{3}x^4$, which is greater than $4x^4$, the product of the two adjacent terms, therefore the sign + is set below the second term; and because the square of the third term multiplied by its overwritten fraction, is $\frac{16}{3}x^2$, which is less than $24x^2$, the product of the terms on each side of it, therefore the sign — is placed under that term; also the sign + is set under the first and last terms. Hence the two changes of the underwritten signs + + — +, the one from + to —, and the other from — to +, shew that the given equation has two impossible roots.

When two or more terms are wanting together, under the place of the first of the deficient terms write the sign —, under the second the sign +, under the third —, and so on, always varying the signs, except that under the last of the deficient terms must always be set the sign +, when the adjacent terms on both sides of the deficient terms have contrary signs. As in the equation,

$$\begin{array}{ccccccc} x^5 & + ax^4 & * & * & * & + a^5 = 0, \\ + & + & - & + & - & + \end{array}$$

which has four imaginary roots.

The author remarks, that this rule will sometimes fail of discovering all the impossible roots of an equation, for some equations may have more of such roots than can be found by this rule, though this seldom happens.

Mr. Maclaurin has given a demonstration of this rule of Newton's, together with one of his own, that will never fail. And the same has also been done by Mr. Campbell. See Phil. Trans. vols. 34 and 35.

The real and imaginary roots of equations may be found from the method of fluxions, applied to the doctrine of maxima and minima; that is, to find such a value of x in an equation, expressing the nature of a curve, made equal to y, an abscissa which corresponds to the greatest and least ordinate. But when the equation is above three dimensions, the computation is very laborious. See Stirling's Treatise on the Lines of the Third Order.

IMPOSTHUME, the same with abscess. See Surgery.

IMPRESSING men. The power of impressing seamen for the sea service, by the king's commission, has been a matter of some dispute, and submitted to with great reluctance, though it has very learnedly been argued by sir Michael Forster, that the practice of impressing, and granting power to the admiralty for that purpose, is of very antient date, and has been continued by a regular series of precedents to the present time, whence he concludes it to be part of the common law. The difficulty arises hence, that no statute has expressly declared this power to be in the crown, though many of them very strongly imply it. The stat. 2 R. II. c. 4. speaks of mariners being arrested and retained for the king's service, as of a thing well known and practised without dispute, and provides a remedy against the running away.

By stat 2 and 3 P. and M. c. 16, if any waterman who uses the river Thames, shall hide himself during the execution of any commission for pressing for his majesty's service, he is liable to heavy penalties. By stat. 5 Eliz. c. 6. no fisherman shall be taken by the queen's commission to serve as a mariner; but the commission shall be first brought to two justices of the peace, inhabiting near the sea-coast where the mariners are to be taken, to the intent that the justices may choose out and return such a number of able-bodied men as in the commission are contained to serve her majesty. And by stat. 7 and 8 W. c. 21.; 2 Anne, c. 6.; 4 and 5 Anne, c. 19.; 13 Geo. II. c. 17.; especial protections are allowed to seamen in particular circumstances, to prevent them from being impressed. All which certainly imply a power of impressing to reside somewhere; and if any where, it must, from the spirit of our constitution, as well as from the frequent mention of the king's commission, reside in the crown alone. 1 Black. 419.

IMPRISONMENT, is the restraint of a man's liberty under the custody of another, and extends not only to a gaol, but a house, stocks, or where a man is held in the street, or any other place; for, in all these cases, the party so restrained is said to be a prisoner so long as he has not his liberty freely to go about his business as at other times.

None shall be imprisoned but by the lawful judgment of his peers, or by the law of the land. Magna Charta.

IMPRISONMENT, *false*. To constitute the injury of false imprisonment, two points are necessary: the detention of the person, and the unlawfulness of such detention. Every confinement of the person is imprisonment, whether it is in a common prison, or in a private house, or in the stocks, or even by forcibly detaining one in the streets. 2 Inst. 589.

By Magna Charta, no freeman shall be taken and imprisoned, but by the lawful judgment of his equals, or by the law of the land: and by the petition of right, 3 C. I. no freeman shall be imprisoned or detained without cause shewn, to which he may make answer according to law. And by the 16 C. I. c. 10. if any person is restrained of his liberty, he may, upon application by his counsel, have a writ of habeas corpus, to bring him before the court of king's bench or common pleas, who shall determine whether the cause of his commitment is just, and thereupon do as to justice appertains.

For false imprisonment the law has not only decreed a punishment by fine and imprisonment, as a heinous public crime, but has also given a private reparation to the party by action at law, wherein he shall recover damages for the loss of his time and liberty. 3 Black. 127.

IMPROPER FRACTIONS. See ARITHMETIC, and ALGEBRA.

IMPROPRIATION, is properly so called when a benefice ecclesiastical is in the hands of a layman; and appropriation when in the hands of a bishop, college, or religious house; though sometimes these terms are confounded. It is said there are 3845 impropriations in England.

IMPULSE, or IMPULSIVE FORCE, the same with impetus. See MECHANICS.

INARCHING, in gardening. See GRAFTING.

INCA, or YNCA, a name given by the natives of Peru to their kings, and the princes of the blood.

INCAPACITY, in the canon law, is of two kinds: 1. The want of a dispensation for age in a minor, for legitimation in a bastard, and the like: this renders the provision of a benefice void in its original. 2. Crimes and heinous offences, which annul provisions at first valid.

INCH, a well-known measure of length, being the twelfth part of a foot, and equal to three barleycorns in length.

INCIDENCE, in mechanics, denotes the direction in which one body strikes on another. See MECHANICS, and OPTICS.

INCLINATION, is a word frequently used by mathematicians, and signifies the mutual approach, tendency, or leaning, of two lines or two planes towards each other, so as to make an angle.

Inclination of a right line to a plane, is the acute angle which that line makes with another right line drawn in the plane through the point where the inclined line intersects it, and through the point where it is also cut by a perpendicular drawn from any point of the inclined plane.

Inclination of the axis of the earth, is the angle which it makes with the plane of the ecliptic; or the angle contained between the planes of the equator and ecliptic.

Inclination of a planet, is an arch of the circle of inclination comprehended between the ecliptic and the plane of a planet in its orbit. See ASTRONOMY.

The greatest inclination of Saturn, according to Kepler, is $2° 32'$; of Jupiter, $1° 20'$; of Mars, $1° 50' 30''$; of Venus, $3° 22'$; of Mercury, $6° 54'$. According to de la Hire, the greatest inclination of Saturn is $2° 33' 30''$; of Jupiter, $1° 19' 20''$; of Mars, $1° 51'$; of Venus, $3° 25' 5''$; of Mercury, $6° 52'$.

Inclination of a plane, in dialling, is the arch of a vertical circle, perpendicular both to the plane and the horizon, and intercepted between them. To find this, let AB (see Plate Misc. fig. 135) be a plane inclined to the horizon HR; apply to the plane AB a quadrant DCF, so that the plummet CE may cut off any number of degrees on the limb, as EF: then the arch DE is the measure of the angle of inclination ABH; for draw BG perpendicular to HR, then because CE is parallel to BG, the angle ECF is equal to CBG; but DCF is equal to GBH, being both right angles, therefore the angle DCF — ECF, is equal to the angle GBH — CBG; that is, DCE is equal ABH.

INCLINED PLANE, in mechanics, one that makes an oblique angle with the horizon. See MECHANICS.

INCOMMENSURABLE, a term in geometry, used where two lines, when compared to each other, have no common measure, how small soever, that will exactly measure them both. And in general, two quantities are said to be incommensurable, when no third quantity can be found that is an aliquot part of both.

Such are the diagonal and side of a square; for though each of those lines has infinite aliquot parts, as the half, the third, &c. yet not any part of the one, be it ever so little, can possibly measure the other, as is demonstrated by Euclid.

INCOMMENSURABLE NUMBERS, are such as have no common divisor that will divide them both equally.

INCORRUPTIBILES, or INCORRUPTICOLÆ, in church history, heretics which had their original at Alexandria, in the time of the emperor Justinian. Their distinguishing tenet was, that the body of Jesus Christ was incorruptible from his conception, by which they meant that after and from the time he was formed in the womb of his holy mother, he was not susceptible of any change or alteration, not even of any natural and innocent passions, as hunger, thirst, &c. so that he ate without any occasion before his death, as well as after his resurrection.

INCUBUS, or NIGHT-MARE. See MEDICINE.

INCUMBENT, a clerk or minister who is resident on his benefice: he is called incumbent, because he does, or at least ought, to bend his whole study to discharge the cure of his church.

INCURVATION *of the rays of light*, their bending out of a rectilinear or straight course, occasioned by refraction.

INDEMNITY, in law, the saving harmless; or, a writing to secure one from all damage and danger that may ensue from any act. An indemnity in regard to estates is called a warranty.

INDENTED, in heraldry, is when the outline of an ordinary is notched like the teeth of a saw.

INDENTED LINE, in fortification, the same with what the French engineers call redent; being a trench and parapet running out and in, like the teeth of a saw, and much used in irregular fortification.

INDENTURE, is a writing containing a conveyance between two or more, indented or cut unevenly, or in and out, on the top or side, answerable to another writing that likewise comprehends the same words. Formerly when deeds were more concise than at present, it was usual to write both parts on the same piece of parchment, with some words or letters written between them, through which the parchment was cut, either in a straight or indented line, in such a manner as to leave half the word on one part, and half on the other: and this custom is still preserved in making out the indentures of a fine. But at last, indenting only has come into use without cutting through any letters at all; and it seems at present to serve for little other purpose than to give name to the species of the deed. 2 Black. 294.

INDEPENDENTS, a sect of protestants in England and Holland, so called from their independency on other churches, and their maintaining that each church or congregation has sufficient power to act and perform every thing relating to religious government within itself, and is no way subject or accountable to other churches or their deputies.

The present independents differ from the presbyterians only in their church government, in being generally more attached to the doctrines distinguished by the term orthodoxy, such as original sin, election, reprobation, &c. and in administering the Lord's supper at the close of the afternoon's service. The several sects of baptists are all independents with respect to church-government; and, like them, administer the Lord's supper in the evening, whereas the presbyterians administer it after the forenoon's service.

INDETERMINATE PROBLEM, in algebra, one which is capable of an indefinite number of solutions.

INDEX, in arithmetic and algebra, shews to what power any quantity is involved, and is otherwise called exponent.

INDEX *of a logarithm*, that which shews of how many places the absolute number belonging to a logarithm consists, and of what nature it is, whether an integer or fraction. Thus, in this logarithm 2.523421, the number 2 standing on the left hand of the point is called the index; because it shews that the absolute number, answering to the above logarithm, consists of three places: for the number is always one more than the index. If the absolute number is a fraction, then the index of the logarithm has a negative sign marked thus $\bar{2}$.523421.

Index *of a globe*, the little style or gnomon, which being fixed on the pole of the globe, and turning round with it, points out the hours upon the hour-circle. See Globe.

INDIAN berry, in commerce, &c. See Coculus.

INDICATIVE, in grammar, the first mood or manner of conjugating a verb, by which we simply affirm, deny, or ask something; as, *amant*, they love; *non amant*, they do not love; *amantne*, do they love?

INDICTION, in chronology, a cycle of 15 years. The Roman or papal indiction, which is that used in the pope's bulls, begins on the 1st of January; and by it the popes have dated their acts ever since Charlemagne made them sovereigns. But besides this, there are other two kinds of indiction mentioned by authors, viz. that of Constantinople, beginning on the 1st of September; and the imperial or Cæsarian indiction, which commenced on the 14th of September. See Cycle.

Indiction is also used for the convoking an ecclesiastical council or assembly.

INDICTMENT, is a written accusation of one or more persons of a crime or misdemeanor, preferred to, and presented on oath by, a grand jury. 4 Black. 302.

An indictment may be found on the oath of one witness only, unless it is for high treason, which requires two witnesses; and unless in any instance it is otherwise specially directed by acts of parliament. 2 Haw.

The sheriff of every county is bound to return to every session of the peace, and every commission of oyer and terminer, and of general gaol-delivery, 24 good and lawful men, of the county, some out of every hundred, to enquire, present, do, and execute, all those things which on the part of our lord the king, shall then and there be commanded therein. As many as appear upon this pannel are sworn of the grand jury, to the amount of twelve at the least, and not more than twenty-three, that twelve may be a majority. This grand jury is previously instructed in the articles of their enquiry, by a charge from the judge on the bench. They then withdraw from court to sit and receive indictments, which are preferred to them in the name of the king, but at the suit of any private prosecutor; and they are only to hear evidence on behalf of the prosecution: for the finding an indictment is only in the nature of an enquiry or accusation, which is afterwards to be tried and determined; and the grand jury are only to enquire upon their oaths whether there is sufficient cause to call upon the party to answer it.

It seems generally agreed, that the grand jury may not find part of an indictment true and part false; but must either find a true bill or ignoramus for the whole; and if they take upon them to find it specially or conditionally, or to be true for part only and not for the rest, the whole is void, and the party cannot be tried upon it, but ought to be indicted anew. 2 Haw. 210.

All capital crimes whatever, and all kinds of inferior crimes which are of a public nature, as misprisions, contempts, disturbances of the peace, oppressions, and all other misdemeanors whatever of a public evil example against the common law, may be indicted, but no injuries of a private nature, unless they in some degree concern the king. And generally where a statute prohibits a matter of public grievance to the liberties and security of a subject, or commands a matter of public convenience, as the repairing of the common streets of the town, &c. every disobedience of such statute is punishable, not only at the suit of the party grieved, but also by way of indictment, for contempt of the statute, unless such method of proceeding shall manifestly appear to be excluded by it. Yet if the party offending has been fined in an action brought by the party (as it is said he may in every action for doing a thing prohibited by statute), such fine is a good bar to the indictment, because by the fine the end of the statute is satisfied; otherwise he would be liable to a second fine for the same offence. 2 Inst. 55.

If several offenders commit the same offence, though in law they are several offences in relation to the several offenders, yet they may be joined in one indictment; as if several commit a robbery, or burglary, or murder. 2 H. H. 173.

No indictment for high treason, or misprision thereof (except indictments for counterfeiting the king's coin, seal, sign, or signet), nor any process or return thereupon, shall be quashed for mis-reciting, mis-spelling, false or improper Latin, unless exception concerning the same is taken and made in the respective court where the trial shall be, by the prisoner or his counsel assigned, before any evidence given in open court on such indictment; nor shall any such mis-reciting, mis-spelling, false or improper Latin, after conviction on such indictment, be any cause or stay, or arrest of judgment; but nevertheless, any judgment on such indictment shall be liable to be reversed on writ of error as formerly.

An indictment accusing a man in general terms, without ascertaining the particular fact laid to his charge, is insufficient; for no one can know what defence to make to a charge which is uncertain, nor can plead it in bar or abatement of a subsequent prosecution; neither can it appear that the facts given in evidence against a defendant on such a general accusation, are the same of which the indictors have accused him; nor can it judicially appear to the court what punishment is proper for an offence so loosely expressed. 2 Haw. 266.

It is therefore best to lay all the facts in the indictment as near to the truth as possible; and not to say, in an indictment for a small assault (for instance) wherein the person assaulted received little or no bodily hurt, that such a one, with swords, staves, and pistols, beat, bruised, and wounded him, so that his life was greatly despaired of; not to say in an indictment for a highway being obstructed, that the king's subjects cannot go thereon without manifest danger of their lives, and the like: which kind of words not being necessary, may stagger an honest man upon his oath to find the fact as so laid.

No indictment can be good without expressly shewing some place wherein the offence was committed, which must appear to have been within jurisdiction of the court. 2 Haw. 236.

There are several emphatical words which the law has appropriated for the description of an offence, which no circumlocution will supply; as *feloniously*, in the indictment of any felony; *burglariously*, in an indictment of burglary, and the like. 2 H. H. 184.

An indictment on the black act for shooting at any person must charge that the offence was done wilfully and maliciously.

By 10 and W. c. 23, it is enacted, that no clerk of assize, clerk of the peace, or other person, shall take any money of any person bound over to give evidence against a traitor or felon for the discharge of his recognizance, nor take more than 2*s.* for drawing any bill of indictment against any such felon, on pain of 5*l.* to the party grieved, with full costs. And if he shall draw a defective bill, he shall draw a new one gratis on the like penalty.

With respect to drawing indictments for other misdemeanors, not being treason or felony, no fee is limited by the statute; the same, therefore, depends on the custom and antient usage.

Every person charged with any felony or other crime, who shall on his trial be acquitted, or against whom no indictment shall be found by the grand jury, or who shall be discharged by proclamation for want of prosecution, shall be immediately set at large in open court, without payment of any fee to the sheriff or gaoler; but in lieu thereof, the treasurer, on a certificate signed by one of the judges or justices before whom such prisoner shall have been discharged, shall pay out of the general rate of the county or district, such sum as has been usually paid, not exceeding 13*s.* 4*d.*

But an action cannot be brought by the person acquitted against the prosecutor of the indictment, without obtaining a copy of the record of his indictment and acquittal; which in prosecutions for felony it is not usual to grant, if there is the least probable cause to found such prosecution upon. For it would be a very great discouragement to the public justice of the kingdom, if prosecutors who had a tolerable ground of suspicion were liable to be sued at law whenever their indictments miscarried. But an action on the case for a malicious prosecution may be founded on such an indictment whereon no acquittal can be, as if it is rejected by the grand jury, or is coram non judice, or is insufficiently drawn; for it is not the danger of the plaintiff, but the scandal, vexation, and expence, upon which this action is founded. However, any probable cause for preferring it is sufficient to justify the defendant, provided it does not appear that the prosecution was malicious. 3 Black. 126.

INDIGOFERA, *the indigo plant*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is patent; the carina of the corolla furnished with a subulated patulous spur on each side; the legumen is linear.

There are 35 species, the most remarkable of which is the tinctoria, a native of the warm parts of Asia, Africa, and America. This plant requires a rich soil, well tilled, and not too dry. The seed of it, which, as to figure and colour, resembles gunpowder, is sown in little furrows that are about the breadth of the hoe, two or three inches deep, at a foot distance from each other, and in as straight a line as possible. Continual attention is required to pluck up the weeds, which would soon choke the plant. Though it may be sown in all seasons, the spring is commonly preferred. Moisture causes this plant to shoot above the surface in three or four days. It is ripe at the end of two months. When it begins to flower, it is cut with pruning-knives; and cut again at the end of every six weeks, if the weather is a little rainy. It lasts about two years, after which term it degenerates: it is then plucked up, and planted afresh. As this plant soon exhausts the soil, because it does not absorb a sufficient quantity of air and dew to moisten the earth, it is of advantage to the planter to have a vast space which may remain covered with trees, till it becomes necessary to fell them in order to make room for the indigo.

The valuable dye-stuff called indigo bears some faint resemblance to starch; but its properties are sufficiently peculiar to distinguish it from all other substances, and its importance entitles it to a distinguished place among vegetable principles. It is commonly procured by the following process:

When the plant has been cut down, it is placed in strata in a large wooden vessel, and covered with water. In this situation it cannot remain long in these warm climates without undergoing some change. Putrefaction, accordingly, very soon commences, or rather a kind of fermentation, which goes on best at the temperature of 80°. The water soon becomes opaque, and assumes a green colour; a smell resembling that of volatile alkali is exhaled, and bubbles of carbonic acid are emitted. When the fermentation has continued long enough, which is judged of by the paleness of the leaves, and which requires from six to twenty-four hours according to the temperature of the air and the state of the plant, the liquid is decanted off the plants into large flat vessels, where it is constantly agitated till blue floculi begin to make their appearance; water is now poured in, which causes the blue flakes to precipitate. The yellow liquid is decanted off, and the blue sediment poured into linen bags. When the water has drained from it sufficiently, it is formed into small lumps, and dried in the shade. In that state it is imported into Europe, and sold under the name of indigo.

The leaves of the indigofera yield a green infusion to hot water, and a green powder may be precipitated from it; but unless a fermentation has taken place, neither the colour nor properties of it have any resemblance to indigo.

Indigo may be obtained from the merium tinctorium, and the isatis tinctoria or woad; a plant commonly enough cultivated in Britain, and even found wild in England When arrived at maturity, this plant is cut down, washed, dried hastily in the sun, ground in a mill, placed in heaps, and allowed to ferment for a fortnight. It is then well mixed, and made up into balls, which are piled upon each other, and exposed to the wind and sun. In this state they become hot, and exhale a putrid ammoniacal smell. The fermentation is promoted, if necessary, by sprinkling the balls with water. When it has continued for a sufficient time, the woad is allowed to fall to a coarse powder; in which state it is sold as a dye-stuff. By treating woad nearly in the same manner with the indigofera, indigo has been obtained from it by different chemists.

Indigo is a fine light friable substance, of a deep-blue colour. Its texture is very compact, and the shade of its surface varies according to the manner in which it has been prepared. The principal tints are copper, violet, and blue; the lightest indigo is the best: but it is always more or less mixed with foreign substances, partly owing, doubtless, to the carelessness of the preparation, and partly to the bodies which the plant containing indigo yields to water. From the analysis of Bergman, to whom we are indebted for one of the most complete treatises on the properties of indigo which has yet appeared, the purest indigo which he could procure, was composed of the following constituents:

47	pure indigo
12	gum
6	resin
22	earth
13	oxide of iron
100.	

The earth consisted of,

10.2	barytes
10.0	lime
1.8	silica
22.0	

But in all probability the earth differs in different specimens; for Proust found magnesia in considerable quantity in the specimens which he examined. The forty-seven parts of blue pigment are alone entitled to the name of indigo; and to them therefore we shall confine our attention.

Indigo is a soft powder, of a deep blue, without either taste or smell. It undergoes no change, though kept exposed to the air. Water does not dissolve any part of it, nor produce any change upon it. Bergman, however, found that indigo, when kept long under water, underwent a kind of putrefaction, or at least exhaled a fetid odour. When heat is applied to indigo, it emits a bluish red smoke, and at last burns away with a very faint white flame, leaving behind it the earthy parts in the state of ashes.

Neither oxygen nor the simple combustibles have any effect upon indigo, except it is in a state of solution; and the same remark applies to the metallic bodies.

The fixed alkaline solutions have no action on indigo, except it is newly precipitated from a state of solution. In that case they dissolve it with facility. The solution has at first a green colour, which gradually disappears, and the natural colour of the indigo cannot be again restored. Hence we see that the alkalies when concentrated decompose indigo. Pure liquid ammonia acts in the same way. Even carbonat of ammonia dissolves precipitated indigo, and destroys its colour; but the fixed alkaline carbonats have no such effect.

Lime-water has scarcely any effect upon indigo in its usual state; but it readily dissolves precipitated indigo. The solution is at first green, but becomes gradually yellow. When the solution is exposed to the air, a slight green colour returns, as happens to the solution of indigo in ammonia; but it soon disappears. The effect of the other alkaline earths upon indigo has not hitherto been tried; but it cannot be doubted that they would act nearly as lime-water, but with more energy. The other earths seem to have but little action on indigo in any state.

The action of the acids upon indigo has been examined with most attention, and it certainly exhibits the most important phenomena.

When diluted sulphuric acid is digested over indigo, it produces no effect, except that of dissolving the impurities; but concentrated sulphuric acid dissolves it readily. One part of indigo, when mixed with eight parts of sulphuric acid, evolves heat, and is dissolved in about 24 hours. According to Haussman, some sulphurous acid and hydrogen gas are evolved during the solution. If so, we are to ascribe them to the mucilage and resin, which are doubtless destroyed by the action of the concentrated acid. The solution of indigo is well known in this country by the name of liquid blue. Bancroft calls it sulphat of indigo. While concentrated it is opaque and black; but when diluted it assumes a fine deep-blue colour; and its intensity is such, that a single drop of the concentrated sulphat is sufficient to give a blue colour to many pounds of water. Bergman ascertained the effect of different reagents on this solution with great precision. His experiments threw light, not only on the properties of indigo, but upon the phenomena that take place when it is used as a dye-stuff. The following is the sum of these experiments:

Dropt into sulphurous acid. Colour at first blue, then green, and very speedily destroyed.—In weak tartaric acid. Becomes gradually green, and in 144 hours had assumed a very pale yellow colour. Colour not restored by alkalies.—In vinegar. Becomes green, and in four weeks the colour disappeared.——In weak potass. Becomes green, and then colourless.——In weak carbonat of potass. The same changes, but more slowly. If the solution is very weak, the colour of the indigo is not destroyed.—In ammonia and its carbonat. Colour becomes green, and then disappears.——In a weak solution of sulphat of soda. Colour after some weeks becomes green.——In tartrat of potass. Became green, and then colourless.——In a solution of sugar. Became green, and at last yellowish.——In sulphat of iron. Colour became green, and in three weeks disappeared.—In the sulphurets. Colour destroyed in a few hours.—Realgar, white oxide of arsenic, and orpiment, produced no change.—Black oxide of manganese destroyed the colour completely.——In the infusion of madder. Colour became green, and at last yellow.—In the infusion of woad, the same changes, but more speedily.

From these experiments it is obvious that all those substances which have a very strong affinity for oxygen give a green colour to indigo, and at last destroy it. Hence it is extremely probable that indigo becomes green by giving out oxygen. Of course it owes its blue colour to that principle. This theory was first suggested by Mr. Haussman, and still farther confirmed by Berthollet. Now it is only when green that it is in a state capable of being held in solution by lime, alkalies, &c. in which state it is applied as a dye to cloth. The cloth when dipt into the vat containing it thus dissolved, combines with it, and the blue colour is restored by exposure to the atmosphere. It may be restored equally by plunging the cloth into oxy-muriatic acid. Hence the restoration cannot but be ascribed to oxygen. Hence, then, the reason that sulphurous acid, the vegetable acids, sulphat of iron, give sulphat of indigo a green colour.

From these experiments we see also that the colour of indigo is destroyed by the addition of those substances which part with oxygen very readily, as the black oxide of manganese. In that case the indigo is destroyed, for its colour cannot be again restored.

Nitric acid attacks indigo with great violence, the evolution of abundance of heat, and nitrous gas. When of the specific gravity 1.52, it even sets fire to indigo. When the acid is diluted the indigo becomes brown, and crystals make their appearance, doubtless consisting of oxalic acid. What remains behind is a brown viscid substance of a very bitter taste, probably analogous to the yellow bitter principle of Welter.

Muriatic acid does not act upon indigo in its common state, but it readily dissolves indigo precipitated from the sulphat, and forms a blue coloured solution. The same phenomena are exhibited by the phosphoric, acetic, tartaric acids, and probably by all, except the acid supporters.

Oxymuriatic acid destroys the colour of indigo as readily as nitric acid, and obviously for the same reason.

Indigo is not acted upon by alcohol, ether, nor oils. The two first solvents, indeed, acquire a yellow colour when digested on common indigo by dissolving its resin.

When indigo is mixed up with bran, woad, and other similar substances, which readily undergo fermentation, it assumes a green colour during the fermentation, and is then easily dissolved by lime or potass. It is by this process that it is usually rendered proper for dyeing.

When indigo is distilled, it yields products different from any other vegetable substance, if the accuracy of Bergman, who alone has made the experiment, is to be trusted. He distilled 576 grains in a small retort connected with a pneumatic apparatus. He obtained the following products:

19 grains	carbonic acid gas
173 ——	of a yellow acid liquid, containing ammonia
53 ——	oil
331 ——	charcoal
576.	

INDIVISIBLES, in geometry, the elements or principles into which any body or figure may be ultimately resolved; which elements are supposed infinitely small: thus a line may be said to consist of points, a surface of parallel lines, and a solid of parallel and similar surfaces; and then, because each of these elements is supposed indivisible, if in any figure a line be drawn through the elements perpendicularly, the number of points in that line will be the same as the number of the elements; whence we may see that a parallelogram, prism, or cylinder, is resolvable into elements or indivisibles, all equal to each other, parallel and like to the base; a triangle into lines parallel to the base, but decreasing in arithmetical proportion; and so are the circles which constitute the parabolic conoid, and those which constitute the plane of a circle, or surface of an isosceles cone.

A cylinder may be resolved into cylindrical curve surfaces, having all the same height, and continually decreasing inwards, as the circles of the base do on which they insist.

The method of indivisibles is only the antient method of exhaustions, a little disguised and contracted. It is found of great use in shortening mathematical demonstrations, of which take the following instance in the famous proposition of Archimedes, viz. that a sphere is two-thirds of a cylinder circumscribing it.

Suppose a cylinder, a hemisphere, and an inverted cone (Plate Miscel. fig. 133) to have the same base and altitude, and to be cut by infinite planes all parallel to the base, of which dg is one. It is plain the square of dh will be every where equal to the square of kc (the radius of the sphere); and consequently, since circles are to one another as the squares of the radii, all the circles of the hemisphere will be equal to all those of the cylinder, deducting thence all those of the cone: wherefore the cylinder, deducting the cone, is equal to the hemisphere; but it is known that the cone is one-third of the cylinder, and consequently the sphere must be two-thirds of it.

INDORSEMENT, in law, any thing written on the back of a deed, as a receipt for money received. See BILLS OF EXCHANGE.

INDUCEMENT, in law, what is alledged as a motive or incitement to a thing, and is used specially in many cases; as, there is an inducement in actions, to a traverse in pleadings, a fact or offence committed, &c.

Inducements to actions need not have so much certainty as in other cases: a general indebitatus is not sufficient where it is the ground of the action; but where it is the inducement to the action, as in consideration of forbearing a debt till such a day (for that the parties are agreed upon the debt), this being but a collateral promise, is good without shewing how due. 2 Mod. 70. An inducement to a traverse must be such matter as is good and justifiable in law. There is an inducement to a justification when what is alledged against it is not the substance of the plea. Moor. 847.

INDUCTION, in law, is the giving a clerk instituted to a benefice the actual possession of the temporalities thereof, in the nature of livery of seisin. It is performed by a mandate from the bishop to the archdeacon, who commonly issues out a precept to some other clergyman to perform it for them; which being done, the clergyman who inducts him indorses a certificate of his induction on the archdeacon's mandate, and they who were present testify the same under their hands, and by this the person inducted is in full and complete possession of all the temporalities of his church.

INDULT, in the church of Rome, the power of presenting to benefices granted to certain persons by the pope. Of this kind is the indult of kings and sovereign princes, in the Romish communion, and that of the parliament of Paris granted by several popes. By the concordat for the abolition of the pragmatic sanction, made between Francis I. and Leo X. in 1516, the French king had the power of nominating to bishoprics, and other consistorial benefices, within his realm. At the same time, by a particular bull, the pope granted him the privilege of nominating to the churches of Brittany and Provence.

INERTIA OF MATTER, in philosophy, is defined by sir Isaac Newton to be a passive principle by which bodies persist in their motion or rest, receive motion in proportion to the force impressing it, and resist as much as they are resisted. It is also defined by the same author to be a power implanted in all matter, whereby it resists any change endeavoured to be made in its state. See MECHANICS.

INFAMY, which extends to forgery, perjury, gross cheats, &c. disables a man to be a witness or a juror; but a pardon of crimes restores a person's credit to make him a good evidence. 2 Haw. 432.

INFANCY, *management and diseases of.* We have been induced to treat of those disorders which are peculiar to infancy separately from other affections, partly by the difference of character which such ailments assume from those of the adult periods of life, and partly by the opportunity the subject will afford of introducing some preliminary observations on the management of infants; observations which we shall endeavour to make familiar and intelligible to the heads of families, or those engaged in conducting the human frame through its more tender and dependant states of existence.

It would be altogether superfluous to urge the importance of this subject. It has been calculated that more than a fourth part of the human race die in the first year after birth; and we have nearly the same evidence that this remarkable mortality originates not in the unchangeable dispositions of nature, but principally from erroneous and perverted management!

In the first division of this article we propose, therefore, to suggest a few hints respecting infantile diet; the regulation of temperature, or external heat; clothing; air, and exercise.

PART I.

SECT. I.—*Diet of infants.*

In the proper nourishment of children we are faithfully instructed by the almost unerring counsels of nature. Where mothers are capable of suckling their offspring, this ought, in no instance, to be omitted: it is, indeed, equally a cause of astonishment and regret that such an obvious and important principle could at any time be neglected or questioned. "See the infant (says a modern writer, while addressing himself to mothers) nourished by your fluids, and brought to a certain degree of perfection while yet in the womb. See him separated from it, and then see his nourishment flowing in another channel. See the secretion and preparation of the milk, the increasing size of the breast, and the formation of the nipples. Behold the economy of the infant himself; see him instinctively taught to search for the breast, and to suck the breast; to draw his nourishment from a new source, yet still from your body, and from your fluids. Did you see this connection sufficiently, you would neither give him over to the suckling of another woman, nor would you feed him with any other substance than your own milk." Dr. Herdman on Infancy.

Dr. Buchan gives it as his opinion, that not one in a hundred of those children survives who are abandoned by their mothers, and committed to the charge of foster-parents in the earliest stages of life; and although we may deem this statement in some measure exaggerated, the reflection of its approach to truth ought to be a sufficient incitement for the appointed and professed guardians of the health and well-being of society to enter a severe and unbiassed protest against the custom to which we now refer.

For the first two or three months the nutriment of the infant ought to be received entirely from the breast of its mother. During the whole of this time its wants are almost confined to nourishment and sleep. It is, however, to be confessed that there are some, although but comparatively few, instances of inability on the part of the parent to furnish milk in due quantity or suitable quality to the requisitions of her offspring. "To the puny progeny of a puny consumptively-disposed mother I would forbid (says Dr. Beddoes) the mother's breast." Now, although we are inclined to suppose that the author just quoted has admitted too much in favour of what is termed rearing by hand (for capacity of bearing is commonly connected with a capacity of nursing children), yet, where circumstances necessarily deprive the child of its regular and more salutary nutriment, it becomes a question of moment, What is to be substituted in its place? Not by any means what the generality of hired attendants direct. As soon as an infant by its cries denotes hunger, the nurse has, for the most part, instant recourse to a mixture of bread and water (pap), which is perhaps spiced, or qualified with a little brandy. To attempt the union of oil and water would be scarcely less incongruous: it is not hazarding any thing to assert, that the major part of infantile ailments are to be attributed to the heterogeneous compounds that are early given to children; and the spicy or spirituous ingredients which are added, in order to force an artificial digestion. The necessity of the latter bears decided evidence against the propriety of the former. In no period of life, during health, ought food to be of such a quality as to require the assistance of condiments or spirits; which last are especially injurious to the assimilating organs of a new-born infant.

About half a tea-cupful of cow's milk, gently warmed, is the only food that ought to be given to a child at its birth, after which it will frequently sleep for ten hours; a symptom which, although often alarming to the obtrusive ignorance of nurses, is to be regarded as a demonstration of the proper nature of the food that has been given, and an indication of future health.

To this plan it is sometimes necessary to have recourse, even when it is the intention of the mother to suckle her child, as women who have had many children frequently have no proper secretion of milk until after the second or third day from delivery.

Before quitting this part of the subject it is proper to observe, that the custom of immediately pouring down purgatives, as if to prove to the little stranger that it has arrived in a world of physic and of evils, is, although very generally adopted, highly injudicious. The bowels do not, in general, require to be thus artificially cleansed.

With respect to the quantity and times of administering food, mothers and nurses are accustomed to err. Nothing can be more improper than to suckle or feed an infant two or three times in the course of an hour. A child judiciously regulated does not demand nourishment, even during the first months, more than once in three or four hours; as it advances it requires feeding even less frequently, and less sleep during the day.

It has already been stated that, with the exceptions pointed out, the mother's breast ought, at least during the first two or three months, to be the sole repository and entire source of infantile nutriment. If the child is brought up by hand, cow's milk gently warmed is all the food that will be necessary for the first four or five months. After these times milk may be alternated, not by moist bread, biscuit, cakes, sugar, panadas, and gruel, but by ground rice or flour well baked; the gravy of boiled meat, which last will generally be taken with avidity; small quantities of beef-tea, or veal-jelly, and other substances of the like nature; still avoiding, unless during the actual existence of disease, and under professional direction, every article in the long list of fermented, fermenting, spicy, and spirituous materials; the withholding of which, however it may offend and alarm the nurse, will be of incalculable benefit to the child.

The time of weaning must be regulated entirely by circumstances. The process should not be abrupt, but gradual. It is very seldom advisable to refuse the breast entirely before the ninth or tenth month.

We have particularly insisted on the necessity of excluding those substances from the diet of infants which are disposed to ferment, or turn sour. A general acquaintance with the laws which regulate the existence and decomposition of such substances may be acquired with less labour than would be requisite to retain in the memory, without the aid of some connecting principle, all the individual articles which are prescribed or admitted as part of the diet in childhood and youth; and in consequence of such pleasing and easy acquisition, we should find knowledge and humanity joining issue in the joyous task of averting the artificial evils which ignorance and error have made to attach to the extremely susceptible, though not naturally unhealthy, state of the primary periods of existence. Whence does the perversity of nurses respecting the treatment of children arise? Solely from ignorance. Were they convinced that the plans which are adopted prove ultimately subversive of their intended object, they would readily consent to abandon them. "Obedience will always be more cheerful and steady after a reasonable explanation." "I have heard a variety of mothers (says Dr. Beddoes) complain that sugar, biscuit, and cakes, disagreed in the most evident manner; and yet that it was impossible, by any injunctions, to prevent the one from being made a part of the food, and the other (sugar) from being given to stop the hiccups, or produce a sensation that should suspend crying for a moment. Now it is well known that perpetually recurring complaints in the stomach and bowels arise from mere sourness; and the parties, by whose mistaken kindness, or by whose delicacy of ear they are occasioned, are perfectly informed so far. It remains only to carry their knowledge a step further. Respecting the juice of the sugar-cane, it is a very striking particular, that the poorest sort will scarcely keep a quarter of an hour in the receiver without turning sour. This can only be *told*. The acescent nature of bread, of sugar, and of the various compositions into which bread and sugar enter, may be *shewn*. For this purpose it is only necessary that a solution of sugar and water should be made into vinegar. In like manner bread and sweet cake should be placed in a heat nearly equal to that of the human body, and the servant be put to taste the infusion when it becomes acid. By an address suited to the object in view, there will surely be small difficulty in giving these simple experiments all the effect that can be desired.

"I shall very contentedly allow the childless wit to laugh at me for the whimsical idea of tutoring nurse-maids in chemistry. I have a balm at hand for any wound the shafts of ridicule may inflict. Considerate parents will avail themselves of so practicable an expedient, and many little sufferers will escape the consequences of an improper regimen. And these are probably (the author might have said *certainly*) far more serious, even in respect to the future than the present. For it clearly results from a contemplation of the manner in which human feelings and ideas gain their connection, that frequent discomposure of the stomach in the morning of life may be instrumental in overcasting its meridian and its close with a cloud of misery, such as neither skill nor fortune can disperse." Beddoes' Hygeia. For further information on the subject of diet, consult the article MATERIA MEDICA, section Dietetics.

SECT. II.—*Of temperature, including remarks on the clothing, and likewise on the washing or bathing, of infants.*

The remarkable success with which the subject of animal temperature has been recently investigated, and the application of facts, deduced from a developement of its laws, to the living system, both in its healthy and disordered state, constitute perhaps the most material improvements in modern physiology and medical practice.

Respecting the generation and adjustment of animal heat, it is not the business of this article to enquire (see PHYSIOLOGY, and MEDICINE); our present plan extends no further than the statement of a few practical rules on the subject of heat and cold, absolutely necessary to be attended to by all who undertake the guardianship of infancy and childhood: "for the management of temperature is of high importance in the treatment of the infant. It runs through, and is connected with, every part of his general treatment. It is to be considered in his dress, in his covering while asleep, in his bathing or washing, in his treatment in the house as well as out of it, in his air and exercise. In short, with a competent knowledge of the management of temperature, a nurse can scarcely go wrong in any part of the general treatment of an infant." Herdman. It must be obvious to every one that the infant at birth necessarily undergoes a sudden and material alteration in the temperature of the medium by which, without clothing, it is surrounded. The effects which would result otherwise from this remarkable change, with respect to external warmth, are in some measure obviated by the immediate commencement of respiration. This, however, is not sufficient of itself to supply the defect of external heat. The change then must be artificially rendered as gradual and imperceptible as possible; and the infant, during the first month, ought scarcely to be exposed to any sensible degree of cold, even for the shortest period. It has been with many midwives a common practice to direct that the new-born child be immediately washed with cold water, and other irritating substances, in order to cleanse the surface of the body previously to its being covered with clothing. All that is necessary, or even proper, is the use of warm water and sponge, without any further friction, after washing, than what is necessary completely to dry the skin; indeed the propriety of washing, or in any way cleansing, the skin of an infant at birth, has lately been denied by an author whom we have already quoted; but we think that the use of tepid water, applied with gentleness, and without any subsequent violence of friction, can in no case be objectionable, but ought always to be had recourse to.

As soon as this process is completed, the infant is to be immediately clothed; and now let the habits of the common routine of nurses and of friends be as sedulously watched, and as earnestly opposed, as in relation to its diet If the customary mode of feeding infants has induced a long train of present and permanent evils, the manner of dressing, (and which, till of very late years, has been persisted in with all the cruel pertinacity of contumacious ignorance), has also been productive of incalculable mischief. The evil is now diminished, but is not by any means destroyed. It has happened in this, as on every other occasion where the clamour of senseless conceits has been made to silence the simple and artless dictates of nature, that the most preposterous customs have obtained. "Physicians speculated about the infant's imperfect structure at birth, about the imperfect structure of his bones, the shapeless forms of his head, and the injuries he might sustain in birth; about injuries and distortions from hurtful motions and unnatural positions. They thought the infant's body unable to support itself, and that even its own motions might destroy it. Then in came the midwives for their share of the concern. The task was theirs to model the head, and to straighten the limbs; to improve upon nature; and to support their improvements by the application of fillets, rollers, and swaddling-bands. They vied with each other who should work the work most cunningly; for, strange to tell, dexterity in working this work of cruelty was reckoned one of their most necessary and important qualifications." Dr. Herdman.

In clothing, then, nothing further is requisite than to guard against the variations of external temperature, and to preserve a genial warmth for the maintenance of functions: the fillets, rollers, and bandages, of the nursery are not useless merely, but beyond measure dangerous. They are to be entirely laid aside, as implements of torture and destruction. No pressure on any part is to be employed. A broad strip of flannel or cotton loosely folded round the body is all that is requisite, even as a bandage for the navel. A thin single cap is the whole of the covering that the head requires or should receive. The body should be enveloped with a shirt of fine cotton, made loose and easy, over which should be a covering of flannel: and in a word, the dress is to be so constructed, that the rapid motion of the circulating fluids may be preserved without the smallest impediment. It may be necessary, before quitting this subject, to state, that the writer's experience has convinced him of the propriety and importance of the above regulations in regard to dress and diet, even where relationship has ensured an attentive and unprejudiced scrutiny into particulars.

But it is not as it regards clothing merely that the medium to which a young infant is exposed demands assiduous attention; much care ought to be taken in providing likewise "a fit habitation for the expected little visitor." The apartment devoted to the rearing of infants, during the first months especially, ought to be so constructed and situated as to ensure a steady, equable, and mild temperature. Small confined nurseries, where it is possible, ought to be avoided. In such apartments it is difficult to guard against the extremes of either heat or cold. An exposure to a stream or current of air, occasioned by an unsuspected breach in the window, directed on the body of a sleeping infant, has often been productive of serious injury. Dr. Beddoes directs that the air of the nursery be never suffered to fall below fifty degrees; and it is always to be carefully retained in the memory, that the deficiencies occasioned by ill-constructed buildings can never be compensated by heaping coals on the fire; by this custom indeed not only is the air rendered impure, but the temperature of the room is made still more irregular, and the danger of colds consequently increased.

There is one caution which is especially necessary with respect to the management and economy of nurseries. All occasions and sources of *damp* should most assiduously be guarded against. This caution is the more needful, because the danger from this source appears to be the least understood or suspected. It is not uncommon to observe that parents and nurses who would dread the opening of a sash-window, at the same time unwittingly expose themselves and their charge to a much greater degree of cold by permitting the suspension of wet clothes, in order to dry, about different parts of the apartment, and even by carelessness respecting the washing of the floor. The process of drying is the process of producing cold, and that too of the most noxious kind; for cold, when combined with moisture, has been proved, in an excessive degree, inimical to the animal economy. Damp is equally insidious and detrimental. We are fully persuaded that from this cause originate many scrophulous and other infantile ailments so peculiarly prevalent in the British isles; and that where the diseases have been fancifully attributed to deleterious impregnations in the waters we drink, and various other sources. By every individual, but more especially by the parents and guardians of infancy and youth, freedom from damp should be the first and great requisite in the choice of apartments and houses.

But to return to the infant's dress. The covering which we have recommended ought to be continued for the first six or seven weeks of infancy; during this period, as we have already observed, nourishment, warmth, and repose, are almost its only requisites. After this time, however, or towards the close of the second month, the infant economy begins to change; vascular action comes now to be connected with voluntary muscular motion; the percipient faculty is gradually developed; and the whole organization appears to undergo a change. The body is now warmed in a greater degree and more regular manner, by actions of its own production, and heat of its own formation. Exterior warmth is daily less necessary; and that quantity and kind of clothing, which before were proper and genial, now become irksome and debilitating. If with this progress of growth the summer months are at the same time about to appear, the covering of the child may, in a short time, be reduced even to a shirt and single external garment: the utility of this light clothing will be rendered evident by the feelings and expressions of the infant. It is almost unnecessary to observe, that general precepts are incapable of undeviating and indiscriminate application. The changes of the weather, the season of the year, and the delicacy or robustness of the constitution, will interfere with every rule, and give exercise to the independant judgment of every parent. Providence, however, has so ordained it, that in this, as in every other respect, the dictates of nature, which are communicated by the desire and aversion of the infant, furnish the most faithful directories with respect to its management; and these are conveyed with such distinctness and precision as to be generally intelligible. It is only by disobeying nature s laws that, in the treatment of infancy, we have wandered wide of the path of rectitude, and are under the necessity of retracing our steps.

We now close the present section by a few additional remarks on the much-contested question of bathing. It has already been observed, that an infant, upon its first entrance into the world, should be immediately washed with tepid or warm water. Others recommend immersion rather than ablution. "For a new-born infant (says Dr. Beddoes) I should prefer instant immersion in water at eighty degrees to washing." It is perhaps immaterial to which mode of cleansing we have recourse, unless the latter may be deemed objectionable on account of the unnecessary shock it may occasion to the tender frame. It is likewise to be observed, that conveniences for the former are procured with more facility than the latter; and that it is not every nursery that can, without difficulty, be furnished with a "proper vessel for a warm bath." The question, however, now to be resolved is, in what mode, and at what temperature, bathing or washing should be continued through the period of childhood. This question, like others, is incapable of decision by an appeal to separate principles. By one writer, daily immersion in, or ablution with, cold water, for the first two or three years of life, is earnestly recommended; by another, it is condemned as an unnecessary piece of cruelty, while tepid washing is directed to supply its place. Like the different decisions past on the cameleon's hue, these precepts, although opposite, may each be equally just. The weakly infant shall be washed "with cold water into irrecoverable debility," into convulsions and death; while to the robust and hardy child the same element at the same temperature shall be congenial, and by its use he will be prepared for the variations of cold and heat, to which he will in the course of life be exposed. In a popular treatise on consumption, recently published by Dr. Reid, we meet with the following judicious regulations on the subject of bathing: "It may be proper to premise (says our author), that by the cold bath is understood water at an inferior standard to eighty degrees of Fahrenheit's thermometer. Between this point and that of 90 degrees the bath may be termed temperate; and it is only beyond this last degree of heat that the epithet warm can with propriety be applied. From neglecting accurately to observe these distinctions, which are of very material importance, a want of precision has often connected itself with directions for the employment of both warm and cold bathing.

"Immersion in cold water, during the period of infancy, has been very generally recommended, and too often had recourse to, in an indiscriminate manner, to preserve health, and ensure hardiness. The author has remarked several instances where sensible, and sometimes considerable, injury has arisen from neglecting to observe the precautions necessary to regulate the employment of this important agent in very early years. In infancy danger to the lungs from cold bathing has been stated to exist in a very inferior degree; and by the practice of dipping children in cold water, susceptibility to the injurious impression of cold, in succeeding years, has been thought to be materially diminished. This principle, in the abstract, is undoubtedly correct; and, with the exceptions and precautions now to be mentioned, may be pursued with propriety and advantage. Two infants may be supposed of one family, of reverse constitutions. In the one a general torpor, debility, and great susceptibility to the impression of cold, shall prevail: in the other comparative vigour, activity, and warmth. That degree of cold which would refresh and invigorate the one, would confirm debility and augment torpor in the other. A bath which is not cold to the sensations must, in the first instance at least, be resorted to for the weaker infant; and in neither case should immersion in cold water be practised when the external warmth of the body is inferior in degree to its general standard; when after immersion the body appears to be chilled, or when returning heat is attended with febrile languor, instead of the grateful and genial warmth characteristic of the appropriate action of exciting powers. If the practice of immersion is guided by a cautious observance of these particulars, it may be adopted with safety, and will be attended with success; but a total neglect of bathing would be greatly preferable to the severe and incautious manner in which infants are frequently exposed to these violent and rapid changes in temperature." It ought to be added, that whether washing or immersion is employed, much care should be taken in drying the skin, particularly in those parts in which it is loosely situated, as about the groin, and in the arm-pits.

It may be necessary likewise to observe, that the breast ought on no account to be given to the child while being washed and dressed. A perseverance in this respect will ultimately prove of essential advantage. The habits of the child are greatly under the command of the parent or nurse. At the expence of a few temporary tears permanent comfort may be attained.

Sect. III.—*Air and exercise.*

It has recently been conjectured that the air we breathe contributes equally, and nearly in the same manner, to the nourishment of the body, with the aliment that is taken into the stomach: respecting the grounds of this opinion it would not be in place, in the present article, to institute any enquiry. (See Physiology; and Materia Medica, section Dietetics). We have here only to impress the necessity of a constant and unremitting regard to ventilation, in order to ensure a healthful condition in the infantile economy.

Both the truth and importance of this principle would seem too obvious even to require notice by a writer on regimen, had he not daily opportunities of witnessing the mischief arising from neglecting its application. The public mind, however, appears to be at length awakening from a long lethargy of prejudice and error. We at length begin to breathe and to live. Even among the poorer and least informed classes of society, cleanliness and ventilation come to be acknowledged as the surest barriers against the invasion of disease. Although, however, on this subject modern science has much to boast, much likewise remains to be accomplished; and even in the present day examples cannot be too frequently pressed upon public observation of the injurious tendency, especially in the susceptible and delicate period of infancy, of neglected ventilation. "There is reason to suppose that, from the inattention of our ancestors to fresh air, multitudes must have perished in the very dawn of existence. In our times grown persons have been dangerously affected by such a deficiency of this necessary of life, as did not even produce immediate uneasiness. *Infants have perished in great numbers by a slow suffocation, terminating in convulsions.* As soon as the want of ventilation was observed the mortality has ceased." Beddoes. A fact, of which the following relation furnishes irrefragable evidence. In the lying-in hospital at Dublin 2,944 infants, out of 7,650, died in the year 1782, within the first fortnight from their birth: they almost all expired in convulsions; many foamed at the mouth, their thumbs were drawn into the palms of their hands, their jaws were locked, their faces swelled, and they presented, in a greater or inferior degree, every appearance of suffocation. This last circumstance at length induced an enquiry whether the rooms were not too close, and insufficiently ventilated. The apartments of the hospital were rendered more airy; and the consequence has been, that the proportion of deaths, according to the register of the succeeding years, is diminished from three to one.

Such facts as these cannot be too often made to pass under review. By the parent anxious for the well-being of her offspring they ought constantly to be enforced upon the minds of servants and nurses, whose supineness in respect to proper ventilation is often only to be equalled by their mismanagement in other particulars. This indolence is often by servants carried to such an extent as very materially to injure their own health. "In a large family (says Dr. Darwin) many female servants slept in one room, which they had contrived to render inaccessible to every blast of air. I saw four who were thus seized with convulsions. They were removed into more airy apartments, but were some weeks before they all regained their health." Had infants unfortunately been confined in the same tainted atmosphere, convulsions in these would have been more readily induced, and might perhaps have proved fatal! A child then ought never, if it can be avoided, to be permitted to sleep with many individuals in the same apartment. It should not be lulled to rest in its nurse's arms. When put to sleep in the couch or cradle the face must not be covered; at night the clothes should be entirely changed; after the first or second month it should be daily taken out in the open air, when the weather is not cold or damp: this is best done in the forenoon, immediately upon being washed and dressed; care being taken that the infant is not carried too much in one position, and that it does not suffer from cold. Every impediment to the purity of the air within doors is to be as speedily as possible removed; and when the skin is preternaturally hot, or the little patient becomes restless and febrile, the fires of the nursery are to be extinguished, the windows thrown open, or the apartments changed.

To the full enjoyment of the atmosphere the free use of the limbs must likewise be added. On exercise scarcely any thing remains to be said. Freedom from all constraint is implied in the mode of dress above recommended. To those, however, who imagine that nature can be assisted by the contrivances of art, or that symmetry of form is to be ensured by unnatural restriction, it may not be improper to observe, that deformities are only known in those countries where mechanical dexterity has been called upon to prevent them. "The infants of the Caffres (says the author of Travels into the interior of Southern Africa), soon after birth, are suffered to crawl about perfectly naked; and at six or seven months they are able to run. A cripple or deformed person is never seen. In Egypt, again, the haram is the cradle or school of infancy. The new-born feeble being is not there swaddled and filleted up in a swathe, the source of a thousand diseases. Laid naked on a mat, exposed in a vast chamber to the pure air, he breathes freely, and with his delicate limbs sprawls at pleasure. The new element in which he is to live is not entered with pain and tears. Daily bathed beneath his mother's eye he grows apace. Free to act he tries his coming powers; rolls, crawls, rises, and, should he fall, cannot much hurt himself on the carpet or mat that covers the floor."

PART II.

DISEASES OF INFANCY.

SEC. I.—*Mesenteric atrophy* (Tabes mesenterica, Atrophia infantilis).

This is, in a great measure, the origin and root of the major part of infantile diseases. An affection of the mesenteric glands in children is often connected with, is not unusually the occasion of, and is still more frequently mistaken for, worms; it is the medium through which rickets are produced; it is, in general, the more immediate cause of diarrhœas, and other bowel complaints; and in several instances has been the "forerunner, if not the cause, of hydrocephalus, or dropsy in the brain."

Than this no complaint bears more evident characters. The physician who has been accustomed to the general aspect of infantile disorders, will most commonly commence his enquiries by an inspection of the abdomen. If he perceives a fulness and tenseness about the navel, and a general protuberance and hardness about the belly, attended sometimes with a knotty irregularity, indicating glandular tumefaction; and if, combined with this symptom, a tendency to atrophy, or, as it is called, falling away in flesh and strength, is observed; a greater or inferior degree of mesenteric consumption is present. Such then are the never-failing attendants of the disorder now under notice; they are its distinct and prominent features. A variety, however, of other adjunctive symptoms, for the most part, display themselves, and constitute part of the malady. Sometimes an universal languor and listlessness will be connected with aversion to food; at others an inordinate appetite is present. The bowels are at times costive, but at others the contrary; the evacuations are discoloured, and unhealthy in their appearance; they are, for the most part, slimy, or viscid in their consistence, but are discharged, both with respect to quantity and quality, with the utmost irregularity: the countenance is pale, "except when the hectic flush prints its deceitful and ill-omened animation on the cheek:" the features are, for the most part, full and tumid: the eye is dull: the breathing is oppressed, and spasmodic: the pulse is invariably feeble, but is sometimes slow, and at others inordinately accelerated. In the advanced stages swellings of the feet and ancles are sometimes observed. The little sufferer generally moans piteously; and this, if the disorder has arrived to any considerable extent, is almost the only sign which is given of consciousness or feeling.

Causes.—Mesenteric atrophy is most prevalent among the children of the poor, especially in large cities, and in dirty confined situations. "The noxious powers producing it," in the language of Dr. Brown, (see BRUNONIAN SYSTEM, vol. I. p. 274) "are the same with those of every other asthenia. They are want of food, or diet of watery matter and bread; cold and moisture, the latter increasing the effects of the former; too little nursing (gestationis justò minus); habitual vomiting and purging; irregularities in the times of sleep, meals, and every other part of infantile management; filth; impure air; an inattention to the instincts of nature in the treatment of children." Elementa Medicinæ. To these causes Dr. Brown ought to have added the practice of giving children fermented or spirituous liquors, and those other artificial stimuli, to which we have referred in the former part of the present essay. This custom is extremely prevalent in the inferior classes of society; and hence, in part, the frequency of mesenteric atrophy among the offspring of the poor.

Immediate cause of, and constitutions most obnoxious to, mesenteric consumptions.—The unusual bulk of the abdomen, which is so characteristic of this disease, obviously depends upon a deranged state of the mesenteric glands. The tumefaction, however, does not arise from the source to which it is vulgarly referred, "the presence of tough, ropy humours, causing an obstruction in the tumefied parts." The theory of mechanical obstruction is indeed totally founded in error. It is inconsistent with the laws of the animal economy. It is incompatible with living action; and, as we shall immediately have occasion to observe, has been the cause of much and serious mischief, both in the domestic, and even the professional treatment, of this and other ailments. "The idea of attenuating humours, purifying blood, and clearing passages, rests upon a wrong principle." So far indeed from the glands of the mesentery being less permeable under disease than when in a state of health, the exact contrary is the fact; and not only is their area enlarged, but new vessels are often at the same time formed; and hence the morbid increase of bulk.

The attendant atrophy is easy of explanation. The deranged action of the glands in question interferes with the due preparation of the chyle, the whole of which has to undergo a preparation in these organs. The chyle is the fluid from which the blood is formed: on the quantity and quality of the blood depend health, growth, and life; by its deficiency, or want of due proportion in its component principles, debility, disease, and atrophy, are produced.

The attendant symptoms are not difficult to account for; the torpid and irregular state of the bowels is partly owing to the general inactivity in the lymphatics of the liver; hence the thinner portions of the bile remain unabsorbed, and this fluid is in consequence too diluted to afford a due excitation to the intestinal fibre. The sliminess and viscidity of the fæces arise from the disordered state of the glands of the intestines; and the œdematous swellings of the feet are evidences of a general inactivity, or deficient excitement, pervading the whole lymphatic system.

The constitutions in which tabes mesenterica most readily makes its appearance, are those which are denominated scrophulous. The marks of scrophula we shall not here enumerate; it may be sufficient to observe, that in habits of this description the lymphatic and glandular systems are especially prone to suffer from the exciting causes of disease. This indeed is more or less the case in every individual during growth, as, at this period of existence, the office which these vessels perform in the animal economy, is more important and complicated than in the succeeding stages of life.

Treatment.—The most effectual remedies are necessarily the converse of those which occasioned the disease. These we shall likewise enumerate from the Elements of Dr. Brown: "nourishing exciting milk; three or four meals in the course of the day, composed chiefly of warm milk; pure animal, and by no means weak, soups, mixed with wheaten flour or bread; a due temperature, so that a genial warmth may be preserved, without producing irritation, or occasioning too copious sweat; avoiding every species of evacuation; good nursing; a proper regulation of the times of sleep, food, and every other circumstance connected with the management of the susceptible and tender condition of infancy; cleanliness; tepid bathing in moderately cold weather, and cold bathing in warm; pure air; being sent out of doors as much as possible, excepting when the weather is damp; and, finally, a judicious attention to desires and propensities; this ought to be carried to such an extent as to obviate, if possible, the most trifling local irritation, as by the scratching of a part that itches."

The above are necessarily adapted to the milder forms of the complaint. When the disorder has arrived to a certain extent, medicinal is now required in aid of domestic treatment: for although the mesenteric atrophy, unless it is a consequence of defective structure, may at all times be prevented, and in its earlier stages with facility combated, without the aid of drugs; these, at length, come to be absolutely indispensable. It ought, however, to be impressed on the public mind, that pharmacy, although it may correct the errors, can in no wise become a substitute for, or supply the deficiencies of, regimen.

The objects of the medical practitioner, in the treatment of the disease in question, will be twofold. 1st. That of immediately and forcibly stimulating the lacteals and mesenteric glands; and, 2dly, the preservation of a due and equable excitement in order to obviate the recurrence of the disorder.

[N. B. For the explanation of any terms that may not be familiar, the reader is referred to the articles ANATOMY, PHYSIOLOGY, and MEDICINE.]

The first of the above intentions is most speedily and effectually accomplished by mercurial purgatives; and of these calomel (submurias hydrargyri) is generally to be preferred. The benefit which has often resulted from preparations of mercury, particularly in the form of calomel, has frequently been accounted for upon very erroneous principles. It is customary to attribute every complaint of childhood, where the stomach and intestines shew marks of derangement, to worms. With the signs of the actual existence of these animalculæ, we have already remarked those of tabes mesenterica are, from their affinity, often confounded. Advertisements of infallible cures for worms, as indeed for every other malady, are constantly before the public: these, for the most part, contain mercury, as the only agent of consequence in their composition; and from the operation of this medicine upon the diseased glands, provided, by accident, the quantity taken is apportioned to the age and constitution of the recipient, immediate, and temporary relief is perceptible. Worms are supposed to be expelled the system, and the infallible medicine is indiscriminately, and often fatally, circulated among the public.

A further error with respect to the agency of calomel in mesenteric affections, is that of attributing its effects solely to its purgative quality. This last error is not confined to the unprofessional. Ill-founded notions, as we have above hinted, are still too general in regard to obstructing humours; and the cure of this disorder, with all others which are conjectured to arise from obstruction, is consequently imagined to be performed by evacuating medicines. We are disposed to believe that a recent publication, although in the main extremely useful, has, by the unqualified recommendation of purgatives, given too much encouragement to this mistaken principle.

Dr. Hamilton, the author of the work to which we allude, has classed, under the title of marasmus, the asthenic affections which are common to young persons, and of which the disorder now under consideration is one of the most general; and these affections he "is convinced have often been removed by the diligent exhibition of purgative medicines." Now we are fully persuaded, although actual, and even repeated, purgations are in many cases indispensable; that for the most part, especially in "incipient marasmus," such a qualification in the dose of cathartics is to be preferred as may ensure an excitation of the glandular, lacteal, and lymphatic organs (the organs principally concerned in the production of the complaints in question), without copiously evacuating the contents of the bowels. For this persuasion we have the authority of experience. Further, it is to be remarked, even where large and repeated evacuations, in these diseases of debility especially, have been followed by beneficial effects, that, even then, the evacuation itself has constituted but a share in the process of recovery. This principle may be evidenced in the example of either vomiting or purging. Let a case be supposed of mesenteric affection carried to such an extent, that the torpid condition of the lacteal glands has extended itself to the hepatic and biliary organs; where even dropsical effusions have taken place, and contributed to the enlargement of the belly; and where this abdominal protuberance is contrasted, in a most distressing degree, with the emaciation of the limbs. Under these circumstances (and the writer of the present article has witnessed them in the full extent described), if either a quantity of ipecacuana, emetic tartar, or any other emetic drug, is given sufficient to occasion vomiting, or such a dose of calomel as alone, or in combination, may produce a copious alvine discharge: the immediate result will prove, that the principal part of the medicinal agency has been constituted by a sudden and powerful impulse communicated to the glandular and absorbent vessels. The liver shall commence a regular secretion of bile, the fæces in consequence assume a proper colour and consistence, the skin shall lose suddenly its sallow sickly hue, the size of the abdomen be lessened, and even the swellings of the ancles be diminished; all evincing, in the most unequivocal manner, an increased action in the absorbent system.

By those who are aware of the importance of acquiring correct notions in respect to medicinal agency, the above remarks, although perhaps in some measure irregularly introduced, will not be deemed misplaced. They will, it is hoped, facilitate the conception, and serve to curtail the discussion, of the remaining disorders that are to be treated of in this article.

We now recur to the more immediate subject of the present section.

We have observed, that the first object of the physician, in cases of deeply rooted mesenteric disorder, is to produce an immediate and forcible excitement in the lacteal glands; the manner in which this object is to be attained may be gathered from the preceding remarks. Either calomel purgatives, or emetic substances, are to be employed, according to the circumstances of the case, or the inclination of the practitioner; and now the judicious regulations of diet and regimen prescribed by Brown, are to be assisted by medicines, in order to accomplish the second purpose, that of preserving a due excitement to secure against the recurrence of the disease.

The physician will be careful to keep in view, that the absorbent system is principally concerned in this, as well as in the other asthenia of infants. It is to this part of the frame that remedies are especially to be directed. Among the various stimuli, those therefore are to be preferred, the influence of which appears in an especial manner to be directed to this part of the organization. Chalybeates have this property in a remarkable degree; and accordingly one or other of the various preparations of steel has been judiciously and successfully had recourse to in tabes mesenterica: these are to be conjoined with pure air, and due exercise, without which the most appropriate medicines will be in vain administered. The continued use of small doses of calomel, or other mercurial preparations, either in conjunction with, and sometimes to the exclusion of, steel, will prove highly useful in restoring a due energy and action to the absorbents. These, like all other active medicinals, require much address and discrimination in their employment. It is from the presence of mercury, as above hinted, that both the utility and dangerous tendency of quack medicines are for the most part derived.

In the practice of the writer of this article, extremely small, and very gradually augmented, doses of digitalis have appeared to restore, in a remarkable degree, the wonted vigour of the lacteal vessels. The free use of this very important and active medicine has long been admitted in dropsy, an affection of the highest debility. In tabes mesenterica we believe its employment is novel; but we are, at the same time, persuaded, from the result of several cases of this and other modifications of infantile asthenia, that foxglove might be made, under due regulation, a very successful agent in the treatment of these complaints. Under these circumstances, on account of the comparative minuteness of the dose, the digitalis is best given in the form of tincture: a preparation which has not hitherto been received into the London Pharmacopeia. See MATERIA MEDICA, and PHARMACY.

SECT. II.—*Water in the head.* (Hydrocephalus.)

The discriminating characters of this disease demand assiduous attention from the medical practitioner. It cannot be doubted that a great number of children are constantly destroyed by water in the brain, where the nature of the malady has been entirely misunderstood, and the symptoms referred to other sources, most commonly worms; while, on the other hand, hydrocephalus has been very frequently suspected, and the event has proved that the suspicion was destitute of any proper foundation.

Hydrocephalus is generally divided by authors into the internal, or that in which the fluid is contained in the ventricles of the brain; and external, where the disease is exterior to the substance of this organ, and the water is found in its investing membranes. The first species has likewise been denominated acute, the second chronic. This division, however, is calculated to mislead; not merely on account of the frequent connection between the two species (internal and external) of hydrocephalus, but because the former, as well as the latter, is oftentimes chronic, and by no means necessarily preceded by an inflammatory affection of the parts concerned in its production.

The chronic internal, chronic external, and the acute, species of hydrocephalus, would constitute a classification of the disease, approaching nearer to accuracy than that which has been hitherto adopted; and we shall proceed to give a brief description of each, requesting the reader to recollect that the different kinds are often mixed, and consequently exhibit characters in an almost endless variety.

Chronic internal.—This, although overlooked in the ordinary division, is perhaps the most usual form in which the affection presents itself; it arises from the same disposition in the habit, and is oftentimes combined with the disease treated of in the preceding section. More commonly, however, it is in a manner vicarious of this last; and the same causes may, perhaps from accidental circumstances, at one time occasion tabes mesenterica, which would at another have produced hydrocephalus. Its symptoms are less decided than those of the other species. When, however, in children of a sluggish habit, or scrophulous constitution, an unusual drowsiness or stupor is present, the child gradually loses his vivacity and spirits, is indisposed to make any exertion of his limbs, is unusually fretful and peevish, complains or exhibits signs of an uneasiness in the head, is affected with convulsive fits without any apparent cause, has an unusually tardy pulse, and more especially if the pupil of the eye is not found to contract upon the application of light, there is reason to suspect the presence of water in the brain, although there may be no symptoms of external disease, and no preternatural enlargement of the head, except what is usually met with in young persons of a torpid scrophulous habit; and the suspicion has been too often confirmed by dissection, even where a fatal termination has happened, without being preceded, during any period of the malady, by the symptoms immediately to be mentioned, characteristic of the acute species. This first kind of hydrocephalus is succinctly described by Dr. Heberden, in the following words: "Capitis dolores, manus ad caput crebro admotæ, clamores subiti, distensio nervorum, stupor, mentis perturbatio, motus venarum lentus, postremo cæcitas." He adds, "Justam hujus morbi suspicionem injicjunt hæc symptomata etiamsi capitis moles non fuerit aucta."

Chronic external.—The head of an infant at, or soon after, the period of birth exhibits a preternatural size and form; the regular process of ossification does not take place; but the principal part of the external surface of the cranium continues soft and yielding, while not unfrequently, in the progress of the complaint, an undulation of a fluid may be perceived by applying the hand to the sutures of the skull. As the disease continues to advance, the signs of its existence become shortly obvious to the most superficial observation; not only does the head increase to an enormous size, but the growth of other parts is in a proportionate ratio defective; the limbs do not often acquire a much greater bulk than at birth; at the ordinary period of teething no teeth present themselves; the percipient faculty is not gradually unfolded, as in other infants; and, indeed, although vitality is preserved, it appears to be a vitality almost entirely unconnected with feeling. In this state of torpid existence life however is, in some instances, prolonged for four, six, or even a greater number of years. In the Commentaries of Van Swieten, we have the relation of life being maintained under this malady for thirty years: this, however, is an anomaly; and indeed the hydrocephalic patient seldom survives the second year.

Acute hydrocephalus.—The acute, phrenitic, inflammatory, or, as it has been termed by some writers, apoplectic hydrocephalus, is not, like the other species, entirely confined to any constitution. Although most frequent in children under twelve years, it is sometimes observed in adults. It has been divided by Dr. Whytt, and others who have followed him, into three distinct stages: the first of which is invariably characterised by a pulse of much celerity and comparative strength; in the second the pulsations become slower, and more feeble; in the third and last period their rapidity is increased even beyond that of the primary stage; but this increased action is now connected with extreme debility. These different changes in the circulation are not, however, always to be traced even in the acute species of hydrocephalus, in that order which the observations of Dr. Whytt would lead us to suppose.

Obscure affections of the stomach, a general feeling of lassitude, with sometimes a kind of palsy of the limbs, or an affection of them, in some measure similar to that observed in St. Vitus's dance, if the child has previously been able to walk, sometimes present themselves as precursors of the first, or the inflammatory stage; at other times the feverish state, intolerance of light, violent pains in the head, and vomiting, are the first signs of disorder that are noticed. These symptoms are in some cases connected, according to the observations of Dr. Rush, with an impatience of sound; the pain of the head is often confined to one side, and in proportion to its intensity the nausea and vomiting become less urgent, while with the remission of the pain these affections of the stomach are disposed to recur. Respiration at this time is spasmodic and irregular; the bowels are generally so costive as to require very drastic purgatives, in order to produce evacuations. This stage of the complaint continues sometimes for several days, but is more usually in a shorter period succeeded by the second, which commences by a sudden reduction of the pulse, and other symptoms of irritation. The pain of the head now becomes less urgent, torpor succeeds to watchfulness, the infant lifts his hands to his head, and frequently utters piercing screams (clamores subiti); a degree of strabismus takes place of the previously morbid susceptibility of light; the little patient lies in an horizontal posture, with the head low, and shows an indisposition to be taken up; the bowels still continue torpid; the urine not unfrequently deposits a thick sediment; and after these symptoms have lasted from seven to fourteen days, the complaint sometimes appears suddenly to decline. This semblance of returning health is, however, deceitful, and is but a prelude to the final period of the complaint: it is now that the pulse increases in frequency, and oftentimes so quick as not to be counted. Dr. Whytt informs us that in some children he has been able to number 210 pulsations in the space of a minute; this extraordinary rapidity, however, does not last through the whole of the day; it comes on and declines with the accessions and remissions of the hectic flush in the cheek. The eyes at length become insensible to the strongest light, convulsions come on, and life is terminated. The duration of this last period, like that of the others, is irregular. Sometimes the patient is carried off in less than a week from its commencement; at other times the child lingers in a hectic state for three, four, or six weeks; and Dr. Monro has informed us, that the last stage has been known to be protracted even to the fourth month.

Causes.—The two first species of the complaint are decidedly of a scrophulous nature. They generally come on without any evident exciting cause, and, like other asthenic affections, in the early periods of life, originate from lymphatic debility, without previous excitement in the vessels of the brain to produce the effusion: the last species is perhaps always preceded by an inflammation in the internal vessels of the brain. The immediate cause of this irritation is not, however, in every instance to be detected; it may arise in subjects predisposed, in common with all other inflammations, from the sudden alternations of cold and heat. It has been observed to supervene upon the contagious eruptive affections, especially when these have been unusually violent; and Dr. Beddoes, in a letter to Dr. Darwin, enquires "whether it may not happen more frequently than has been suspected from external injury?" Zoonomia.

Treatment.—Evacuations of every kind, viz. cathartics, sudorifics, emetics, general and local blood-letting, as well as the external application of cold, and of blisters to the scalp, with due attention to the erect position of the head, had all, in conjunction or separately, been tried in the acute species of hydrocephalus, but, according to the general report of physicians, without effect.

In consequence, therefore, of the ill success that had attended the common routine of treatment in hydrocephalus, Dr. Dobson, of Liverpool, was induced to make trial of mercurials, with an intention of exciting the absorbents of the brain, and in this manner removing the extravasated fluid. The event appeared to justify his theory; and we have several cases recorded by this physician and by others, in which mercury, carried to the extent of salivation, accomplished a speedy and effectual cure. The following case is from Dr. Percival: "One of my own children, a girl, aged three years and three months, has lately been a severe sufferer under this alarming malady. As soon as the characteristic symptoms of the disease clearly manifested themselves, I laid aside all other remedies, convinced by repeated observation of their insufficiency, and trusted solely, though with much solicitude, to the internal and external use of mercury. In forty-eight hours, signs of amendment appeared, and her recovery was perfected in six days. During this space of time, thirteen grains of calomel were administered, and seven scruples of unguentum mercuriale fortius carefully rubbed into the legs."

With the same design of exciting the absorbents, digitalis has recently been employed. "In one child," says Dr. Darwin, "I tried the foxglove in tincture, but it was given with too timid a hand and too late in the disease to determine its effects." In the work of Dr. Reid, to which we referred in a former part of this article, we meet with the following observations: "The universality of lymphatic absorbents is rather conceived than actually demonstrated. Dissection has hitherto not been able to detect these vessels in the brain; analogy, however, favours the supposition of their existence. If that frequent and too fatal disease of young persons, water in the brain, admits of cure, the remedies which effect it, must necessarily operate by producing an absorption of the effused fluid. The author imagines he has witnessed the cure of hydrocephalus by means of foxglove. The symptoms, however, of worms and other infantile affections, so often resemble those indicative of water in the ventricles of the brain, that it is scarcely possible to decide with absolute certainty on the interesting question of the inevitable fatality or remediable nature of hydrocephalus."

If foxglove should be proved by future experience to succeed as a remedy for this alarming malady, its modus operandi must be referred to the extraordinary faculty which it possesses of repressing the arterial, while it stimulates the absorbent system. Both in the acute and chronic hydrocephalus, it appears to be deserving of a more extensive trial. To the earlier stages of the former we should, *a priori*, be disposed to conceive it more applicable than even mercury.

SECT. III.—*Worms.* (Vermes.)

The marks by which the presence of worms is indicated are confessedly at times, both in the infant and adult, obscure and equivocal. In the majority of cases, however, the phenomena which they present require only for their detection a careful and discerning scrutiny.

In persons affected with worms, the countenance in general has a peculiarly livid and dirty kind of appearance, very different from that which characterizes mere lymphatic debility, as in tabes mesenterica, and hydrocephalus. The eyes become dull, the pupil dilated, but not averse to light, as in hydrocephalus, the upper lip swelled, the sides of the nostrils enlarged, and there is almost constantly a violent itching of their internal membrane. The breath is remarkably offensive, saliva is secreted in unusual abundance; during sleep there is most generally some grinding of the teeth, and epileptic affections are by no means uncommon; the pulse is intermittent, the febrile irritation is not always of the hectic kind, the appetite is often voracious, lancinating pains are complained of in the stomach and bowels, and tenesmus, attended with a distressing irritation about the anus, is, especially from some species of worms, exceedingly frequent. Cough is not uncommon. These last, however, are more frequent symptoms in the adult than in the child. See MEDICINE.

Causes.—"The tumid belly, bloated countenance, and swelled upper lip," says Dr. Darwin, "are concomitant circumstances attending the general inactivity of the absorbent system, which is therefore to be esteemed the remote cause of the generation of worms." Worms, however, are often produced through the medium of intestinal viscidities, independantly of the absorbent vessels. The immediately exciting causes are some of those already mentioned as productive of mesenteric atrophy, more especially the reception into the stomach of indigestible substances. Dr. Darwin, indeed, supposes, that not merely the nidus of worms is thus formed from aliment incapable of assimilation, but that these animalculæ are actually received from without: for this opinion, however, there does not appear any foundation. Worms are actually engendered in the alimentary passage.

Treatment.—Emetics; mercurial purgatives; chalybeates; vegetable bitters; avoiding indigestible aliment. For an account of the different kinds of worms, and specific anthelmintics, consult the articles MEDICINE, and MATERIA MEDICA.

SECT. IV.—*Rickets.* (Rachites. Atrophia infantilis.)

This is likewise an affection of the lymphatic system. Every one knows the characters by which it is marked. An infant with a large head, protuberant forehead, swellings in the smaller joints, depressed flattened ribs, emaciated limbs, and tumid abdomen, is decidedly rickety. These symptoms, in common with the other asthenia of infants, usually make their appearance before the second year. The first indication of a rickety tendency is a remarkable flaccidity of the muscular fibre; disinclination to exertion follows; and the irregularities above enumerated shortly supervene, followed by hectic, cough, confirmed atrophy, death, or permanently distorted limbs.

Causes.—Debility, most commonly of an hereditary nature, constitutes the predisposition to rickets. Bad air, bad nursing, improper diet, uncleanliness, and damp, are its exciting causes. Hoffman describes the proximate cause to be a deficient supply of nervous influence to the spinal marrow, preventing the due nutrition of parts. Dr. Cullen supposes, a deficiency of bony matter in the fluids constitutes the disease. A more correct account, however, of the essentials of rickets, would make it to consist in deficient excitement or power in those vessels, by the action of which osseous matter is thrown out, and bone constituted.

Treatment.—Indication 1st. To cleanse the first passages from obstructions. Methodus medendi: emetics, cathartics, calomel.

Indication 2d. To restore due energy to the secretory vessels of the bones. M. M. chalybeates, exercise, bathing.

SECT. V.—*Disorder in the bowels.* (Diarrhœa infantilis.)

Among the morbi infantiles in the yearly catalogue of every medical practitioner, diarrhœa occupies a conspicuous situation. The griping, green and otherwise discoloured fæces, pains in the abdomen, with drawing up of the knees towards the stomach, severe crying, febrile irritation, and a greater or less degree of actual convulsion, are perhaps the most common among the diseases of infancy.

Causes.—These affections, as we have already observed, are almost invariably occasioned by improper diet. Dr. Darwin gives us the following relation: "A child of a week old, which had been taken from the breast of its dying mother, and had by some uncommon error been suffered to take no food but water-gruel, became sick and griped in 24 hours, was convulsed on the second day, and died on the third!" He adds, "That among the poor children of Derby who are thus fed hundreds are starved into scrophula, and either perish or live in a state of wretched debility." Zoonomia.

Treatment.—Calomel, with rhubarb, is to be immediately given, which is to be followed by antacids, such as prepared chalk and magnesia. With these are to be connected, according to the violence of the disorder, aromatics and stimulants, such as cinnamon, nutmeg, and opium. Sometimes it is necessary to give an emetic. In all cases indigestible food is to be avoided.

SECT. VI.—*Affections occasioned by teething.* (Dentitio.)

Pains in the head, convulsions, frequent and sudden startings, more especially in sleep, eruptions on the skin, disorders of the stomach and bowels, cough, and hectic fever, are not unfrequently occasioned by the process of toothing. Dr. Darwin conjectures, that "the pain of toothing often begins much earlier than is suspected;" and that the apparent cause of the disease is in reality its cure, as the convulsions, which are oftentimes the most violent and then by far the most alarming of the above symptoms, are commonly relieved when "the gum swells and becomes inflamed; at other times a diarrhœa supervenes, which is generally esteemed a favourable circumstance."

In difficult dentition, the pains in the head, convulsions, vomiting, and hectic, sometimes give rise to the suspicion of hydrocephalus: from this, however, the disease in question may generally be distinguished with facility by the ease with which, in the last case, the bowels are evacuated; by the inflammatory redness of the gum, and by the pupil of the eye being dilated in an obscure, and contracted in a vivid light, the contrary of which takes place in hydrocephalus.

Treatment.—Frequent doses of rhubarb, with magnesia, will often allay the intestinal irritation, and mitigate the teething cough. The gums are to be lanced in all cases where the redness and swelling are considerable. This practice can indeed never be objectionable. Antispasmodics for the convulsions are inefficacious while the cause remains.

SECT. VII.—*Croup.* (Cynanche trachealis.)

The characteristics, or pathognomic symptoms of this disease are, difficult respiration, loud and stridulous cough, with the emission of a sound of a peculiar nature, which has been compared to the crow of a young cock.

These symptoms sometimes supervene upon the common precursors of violent inflammation; at other times the disease is formed without previous warning, and has been known to prove fatal in a very few hours from its apparent commencement. If life is not speedily terminated in this manner, the disorder frequently runs on for the space of six days, and terminates for the most part by crisis, with the evacuation of much pale urine.

Causes.—The croup is an inflammation of the upper part, as the peripneumony is of the lower part of the same organ, viz. the trachea or windpipe. It originates from the same sources as other inflammation. The circumstance of its frequent occurrence and fatal tendency in infants, appears to be owing to the extremely disproportionate smallness of the glottis at this period of life. The cause of death, when it happens suddenly, is a deposition of concreted mucus (consequent upon the inflammation), which lines the trachea, and fills up the bronchial cavities. Independantly, however, of this circumstance, sudden death may be occasioned by the great loss of power in the muscular fibres of the glottis, induced by the previously high excitement, "infantes enim miram incitationis vicissitudinem, brevissimis temporum spatiis, experiuntur."

Treatment.—This, to be effectual, must be speedy and decisive. Emetics; copious bleeding by leeches, applied near to the part affected; blisters; warm bath; antimonials. Recently, calomel in large doses has been tried, and with success. Might not digitalis prove useful in consequence of its extraordinary power in rapidly reducing arterial excitement?

N. B. Croup, in some instances, assumes more of the asthenic than of the inflammatory nature; and in this case the disorder of the glottis is often protracted to a longer period. The treatment in this latter species requires to be stimulating. Calomel; opiates; blisters; volatile embrocations to the throat; nourishing diet.

For those diseases of young persons which often require local, in connection with general treatment, such as distortions of the spine, affections of the eyes, scrophulous swellings of lymphatic glands, &c. consult the article SURGERY.

For eruptive and contagious diseases, see MEDICINE.

INFANT. From the observations daily made on the actions of infants, as to their arriving at discretion, the laws and customs of every country have fixed upon particular periods, on which they are presumed capable of acting with reason and discretion; in our law the full age of man or woman is 21 years. 3 Bac. Abr. 118.

The ages of male and female are different for different purposes: a male at 12 years of age may take the oath of allegiance; at 14 is at discretion, and therefore may consent or disagree to marriage, may choose his guardian, and if his discretion is actually proved, may make his testament of his personal estate; at 17 he may be a procurator or an executor; and at 21 is at his own disposal, and may alien his lands, goods, and chattels. A female at seven years of age may be betrothed or given in marriage; at nine is entitled to dower; and at 12 is of years of maturity, and therefore may consent or disagree to marriage, and if proved to have sufficient discretion may bequeath her personal estate; at 14 is at years of legal discretion, and may choose a guardian; at 17 may be executrix; and at 21 may dispose of herself and her lands. 1 Black. 463.

An infant is capable of inheriting, for the law presumes him capable of property; also an infant may purchase, because it is intended for his benefit, and the freehold is in him till he disagrees thereto, because an agreement is presumed, it being for his benefit, and because the freehold cannot be in the grantor contrary to his own act, nor can be in abeyance, for then a stranger would not know against whom to demand his right; and if at his full age the infant agrees to the purchase, he cannot afterwards avoid it; but if he dies during his minority his heirs may avoid it, for they shall not be bound by the contracts of a person who wanted capacity to contract. Co. Litt. 2.

As to infants being witnesses, there seems to be no fixed time at which children are excluded from giving evidence; but it will depend in a great measure on the sense and understanding of the children, as it shall appear on examination in court. Bull. N. P. 293.

And where they are admitted, concurrent testimony seems peculiarly desirable. 4 Bla. 214.

An infant is not bound by his contract to deliver a thing; so if one deliver goods to an infant upon a contract, &c. knowing him to be an infant, he shall not be chargeable in trover and conversion, or any other action for them; for the infant is not capable of any contract but for necessaries, therefore such delivery is a gift to the infant; but if an infant, without any contract, wilfully takes away the goods of another, trover lies against him; also it is said, that if he takes the goods under pretence that he is of full age, trover lies, because it is a wilful and fraudulent trespass. 1 Sid. 129.

Infants are disabled to contract for any thing but necessaries for their person, suitable to their degree and quality; and what is necessary must be left to the jury. Co. Litt. 172.

An infant, knowing of a fraud, shall be as much bound as if of age. 13 Vin. Abr. 536. But it is held that this rule is confined to such acts only as are voidable; and that a warrant of attorney given by an infant being absolutely void, the court will not confirm it, though the infant appeared to have given it, knowing it was not good, and for the purpose of collusion.

As to acts of infants being void, or only voidable, there is a diversity between an actual delivery of the thing contracted for, and a bare agreement to deliver it; the first is voidable, but the last absolutely void.

As necessaries for an infant's wife are necessaries for him, he is chargeable for them, unless provided before marriage; in which case he is not answerable, though she wore them afterward. 1 Str. 168.

An infant is also liable for the nursing of his lawful child.

Where goods are furnished to the son, he is himself liable if they are necessaries. If tradesmen deal with him, and he undertakes to pay them, they must resort to him for payment; but if they furnished the infant on the credit of his father, the father only is liable. 2 Esp. 471.

With respect to education, &c. infants may be charged, where the credit was given bona fide to them. But where the infant is under the parent's power, and living in the house with them, he shall not be liable even for necessaries. 2 Black. Rep. 1325.

If a taylor trusts a young man, under age, for clothes to an extravagant degree, he cannot recover; and he is bound to know whether he deals at the same time with any other taylor. 1 Esp. Rep. 212.

If one lends money to an infant to pay a debt for necessaries, and he pays it, although he is not bound in law, it is said he is in equity; but if the infant misapplies the money it is at the peril of the lender.

A promissory note given by an infant for board and lodging, and for teaching him a trade, is valid, and will support an action for the money. 1 T. R. 41.

And debts contracted during infancy are good considerations to support a promise made to them when a person is of full age; but the promise must be express.

A bond without a penalty for necessaries will bind an infant, but not a bond with a penalty. Esp. Rep. 164.

Legacies to infants cannot be paid either to them or their parents.

An infant cannot be a juror, neither can he be an attorney, bailiff, factor, or receiver. Co. Lit. 172.

By the custom of London an infant unmarried, and above the age of 14, if under 21, may bind himself apprentice to a freeman of London, by indenture with proper covenants, which covenants, by the custom of London, will be as binding as if of age.

If an infant draws a bill of exchange, yet he shall not be liable on the custom of merchants; but he may plead infancy in the same manner as he may to any other contract.

An infant cannot be sued but under the protection and joining the name of his guardian; but he may sue either by his guardian, or his next friend, who is not his guardian. Co. Lit. 135.

An action on an account stated will not lie against an infant, though it should be for necessaries. Co. Lit. 172.

INFINITE, or INFINITELY GREAT LINE, in geometry, denotes only an indefinite or indeterminate line, to which no certain bounds, or limits, are prescribed.

INFINITESIMALS, among mathematicians, are defined to be infinitely small quantities.

In the method of infinitesimals, the element, by which any quantity increases or decreases, is supposed to be infinitely small, and is generally expressed by two or more terms, some of which are infinitely less than the rest, which being neglected as of no importance, the remaining terms form what is called the difference of the proposed quantity. The terms that are neglected in this manner, as infinitely less than the other terms of the element, are the very same which arise in consequence of the acceleration, or retardation, of the generating motion, during the infinitely small time in which the element is generated; so that the remaining terms express the elements that would have been produced in that time, if the generating motion had continued uniform: therefore those differences are accurately in the same ratio to each other as the generating motions or fluxions. And hence, though in this method infinitesimal parts of the elements are neglected, the conclusions are accurately true without even an infinitely small error, and agree precisely with those that are deduced by the method by fluxions.

For example (see Plate Miscel. fig. 136), when DG, the increment of the base AD, of the triangle ADE, is supposed to become infinitely little, the trapezium DGHE (the simultaneous increment of the triangle) consists of two parts, the parallelogram EG, and the triangle EIH; the latter of which is infinitely less than the former, their ratio being that of one-half DG to AD: therefore, according to this method in fluxions, the part EIH is neglected, and the remaining part, viz. the parallelogram EG, is the difference of the triangle ADE. Now it might be shewn, that EG is precisely that part of the increment of the triangle ADE which is generated by the motion with which this triangle flows, and that EIH is the part of the same increment which is generated in consequence of the acceleration of this motion, while the base, by flowing uniformly, acquires the augment DG, whether DG be supposed finite or infinitely less.

Example 2. The increment DELMHG (fig. 137) of the rectangle AE, consists of the parallelograms EG, EM, and I*h*; the last of which, I*h*, becomes infinitely less than EG, or EM, when DG and LM, the increments of the sides, are supposed infinitely small; because I*h* is supposed to be to EG as LM to AL, and to EM as DG to AD; therefore, I*h* being neglected, the sum of the parallelograms EG and EM is the difference of the rectangle AE: and the sum of EG and EM is the space that would have been generated by the motion with which the rectangle AE flows continued uniformly, but that I*h* is the part of the increment of the rectangle which is generated in consequence of the acceleration of this motion, in the time that AD and AL, by flowing uniformly, acquire the augments DG and LM. The same may be observed in propositions wherein the fluxions of quantities are determined; and thus the manner of investigating the differences, or fluxions of quantities, in the method of infinitesimals, may be deduced from the principles of the method of fluxions. For instead of neglecting EIH because it is infinitely less than EG, (according to the usual manner of reasoning in that method), we may reject it; because we may thence conclude, that it is not produced in consequence of the generating motion DG, but of the subsequent variations of this motion. And it appears why the conclusions in the method of infinitesimals are not to be represented as if they were only near the truth, but are to be held as accurately true.

In order to render the application of this method easy, some analogous principles are admitted, as that the infinitely small elements of a curve are right lines, or that a curve is a polygon of an infinite number of sides, which being produced, give the tangents of the curve; and by their inclination to each other measure the curvature. This is as if we should suppose, when the base flows uniformly, the ordinate flows with a motion which is uniform for every infinitely small part of time, and increases or decreases by infinitely small differences at the end of every such time.

But however convenient this principle may be, it must be applied with caution and art on various occasions. It is usual therefore, in many cases, to resolve the element of the curve into two or more infinitely small right lines; and sometimes it is necessary, if we would avoid error, to resolve it into an infinite number of such right lines, which are infinitesimals of the second order. In general, it is a postulatum in this method, that we may descend to the infinitesimals of any order whatever, as we find it necessary; by which means any error that might arise in the application of it may be discovered and corrected by a proper use of this method itself. For an example of this, see Maclaurin's Fluxions.

INFLAMMABILITY, that property of bodies which disposes them to kindle or catch fire. See Caloric, Chemistry, &c.

INFLAMMATION. See Surgery, and Medicine.

INFLECTION, or *point of inflection*, in the higher geometry, is the point where a curve begins to bend a contrary way. See Flexure.

To determine the point of inflection in curves, whose semi-ordinates CM, Cm (Pl. Miscel. fig. 184) are drawn from the fixed point C; suppose CM to be infinitely near Cm, and make mH = Mm; let Tm touch the curve in M. Now the angles CmT, CMm, are equal; and so the angle CmH, while the semi-ordinates increase, does decrease, if the curve is concave towards the centre C, and increases if the convexity turns towards it. Whence this angle, or, which is the same, its measure, will be a minimum or maximum, if the curve has a point of inflection or retrogression; and so may be found, if the arch TH, or fluxion of it, be made equal to 0, or infinity. And in order to find the arch TH, draw mL, so that the angle TmL be equal to mCL; then if C$m = y$, $mr = x$, mT $= t$, we shall have $y : \dot{x} :: \dot{t} : \frac{t\ddot{x}}{y}$. Again, draw the arch HO to the radius CH; then the small right lines mr, OH, are parallel; and so the triangles OLH, mLr, are similar; but because HI is also perpendicular to mL, the triangles LHI, mLr, are also similar; whence $\dot{t} : \dot{x} :: y : \frac{\dot{x}\ddot{y}}{\dot{t}}$; that is, the quantities mT, mL, are equal. But HL is the fluxion of Hr, which is the distance of Cm $= y$; and HD is a negative quantity, because while the ordinate CM increases, their difference rH decreases; whence $\dot{x}x + \dot{y}y - \dot{y}\dot{y} = 0$, which is a general equation for finding the point of inflection, or retrogradation. See Fluxions.

INFORMATION, in law. An information may be defined an accusation or complaint exhibited against a person for some criminal offence, either immediately against the king, or against a private person, which, from its enormity or dangerous tendency, the public good requires should be restrained and punished. It differs principally from an indictment in this, that an indictment is an accusation found by the oath of 12 men, but an information is only the allegation of the officer who exhibits it. 3 Bac. Abr. 164.

Informations are of two kinds: first, those which are partly at the suit of the king, and partly at the suit of a subject; and, secondly, such as are only in the name of the king: the former are usually brought upon penal statutes, which inflict a penalty on conviction of the offender, one part to the use of the king, and another to the use of the informer; and are called qui tam, or popular actions, only carried on by a criminal instead of a civil process.

Informations that are exhibited in the name of the king alone are also of two kinds: first, those which are truly and properly his own suits, and filed ex officio by his own immediate officer, the attorney-general; secondly, those in which, though the king is the nominal prosecutor, yet it is at the relation of some private person, or common informer; and they are filed by the master of the crown office, under the express direction of the court. The objects of the king's own prosecutions, filed ex officio by the attorney-general, are properly such enormous misdemeanours as peculiarly tend to disturb or endanger the government. The objects of the other species of informations, filed by the master of the crown office, upon the complaint or relation of a private subject, are any gross and notorious misdemeanors, riots, batteries, libels, or other immoralities, of an atrocious kind, not peculiarly tending to disturb the government, but which, on account of their magnitude or pernicious example, deserve the most public animadversion. And when an information is filed either thus, or by the attorney-general ex officio, it must be tried by a petty jury of the county where the offence arises; after which, if the defendant is found guilty, he must resort to the court of king's bench for his punishment. 4 Black. 308.

If a common informer should willingly delay his suit, or discontinue, or be nonsuit, or shall have a verdict or judgment against him, he shall pay costs to the defendant. 18 Eliz. c. 5.

And in the court of king's bench, particularly if the defendant shall appear and plead to issue, and the prosecutor shall not at his own costs, within a year after issue joined, procure the same to be tried; or if a verdict pass for the defendant, or the informer procure a noli prosequi to be entered; the said court of king's bench may award the defendant his costs, unless the judge shall certify that there was a reasonable cause for exhibiting such information; and if the informer shall not, in three months after such costs taxed, and demand made, pay the same, the defendant shall have the benefit of the recognizance, to compel him thereunto. 4 and 5 W. c. 18.

INFRALAPSARIANS, in church history, an appellation given to such predestinarians as think the decrees of God, in regard to the salvation and damnation of mankind, were formed in consequence of Adam's fall.

INFUSION, a method of obtaining the virtues of plants, roots, &c. by steeping them in a hot or cold liquid.

INFUSORIA, in natural history, minute simple animalcules, seldom visible to the naked eye. When water is examined with the microscope, particularly that which has long been stagnant, and has vegetable matter growing in it, or water in which vegetables have been infused, thousands of minute animals have been discovered, which have been arranged together in this order. When wheat that is richety is infused in water, small eel-shaped worms are discovered, which were the cause of the disease. Wheat thus injured is very different from smutty wheat. The grains are brown, shrivelled, and of irregular forms; each contains one or more of these worms, which lie dormant as long as the grain is dry; but as soon as it is moistened by being sown, or otherwise, the worms are revivified, feed on the flour, and lay their eggs. If such grain vegetates, the young, as soon as they are hatched, eat their way up the stem, and bury themselves in the young succulent ear.

INGRESS, in astronomy, signifies the sun's entering the first scruple of one of the four cardinal signs, especially Aries.

INGROSSER. See Forestalling.

INHALER, in medicine, a machine for steaming the lungs with warm water, recommended by Mr. Mudge in the cure of the catarrhous cough. The body of the instrument resembles a porter-pot, holds about a pint, and the handle, which is fixed to the side of it, is hollow. In the lower part of the vessel, where it is soldered to the handle, is a hole, by means of which and three others on the upper part of the handle, the water, when it is poured into the inhaler, will rise to the same level in both. To the middle of the cover a flexible leathern tube, about six or seven inches long, is fixed, with a mouth-piece of wood or ivory. In the cover there is a valve fixed, which opens and shuts the communication between the upper and internal part of the inhaler and the external air. This valve is extremely simple: being formed only of a short tube descending inwards from the cover, and having beneath a small hole upon which a ball of cork plays. When the mouth is applied to the end of the tube in the act of inspiration, the air rushes into the handle, and up through the body of warm water, and the lungs become, consequently, filled with hot vapour. In exspiration, the mouth being still fixed to the tube, the breath, together with the steam on the surface of the water in the inhaler, is forced up through the valve in the cover.

INHERITANCE, is a perpetuity in lands or tenements to a man and his heirs; and the word inheritance is not only intended where a man has lands or tenements by descent, but also every fee-simple, or fee-tail, which a person has by purchase, may be said to be an inheritance, because his heirs may inherit it. Lit. s. 9.

Inheritances are corporeal or incorporeal. Corporeal inheritances relate to houses and lands which may be touched or handled; and incorporeal hereditaments are rights issuing out of, annexed to, or exercised with, corporeal inheritances; as advowsons, tithes, annuities, offices, commons, franchises, privileges, and services. 1 Inst. 49.

There are several rules of inheritances of lands, according to which estates are transmitted from ancestor to heir, viz. 1. That inheritances shall lineally descend to the issue of the person last actually seized, in infinitum, but shall never lineally ascend. 2. The male issue shall be admitted before the female. 3. Where there are two or more males in equal degree the eldest only shall inherit; but the females all together. 4. The lineal descendants, in infinitum, of any person deceased shall represent their ancestor; that is, shall stand in the same place as the person himself would have done had he been living: thus the child, grandchild, or great-grandchild (either male or female), of the eldest son, succeeds before the younger son, and so in infinitum. 5. On failure of issue of the person last seized, the inheritance shall descend to the blood of the first purchaser. 6. The collateral heir of the person last seized must be his next collateral kinsman of the whole blood. 7. In collateral inheritances the male stocks shall be preferred to the female, unless where lands are descended from a female: thus the relations on the father's side are admitted in infinitum before those on the mother's side are admitted at all; and the relations of the father's father before those of the father's mother, and so on. 2 Black. c. 14.

INHIBITION, a writ to inhibit or forbid a judge from farther proceedings in the cause depending before him. F. N. B. 39.

INJUNCTION. An injunction is a prohibitory writ, restraining a person from committing or doing a thing which appears to be against equity and conscience. 3 Bac. Abr. 172.

An injunction is usually granted for the purpose of preserving property in dispute pending a suit; as to restrain the defendant from proceedings at the common law against the plaintiff, or from committing waste, or doing any injurious act. Milf. Treat. Chan. Plead.

Injunctions issue out of the courts of equity in several instances. The most usual injunction is to stay proceedings at law; as, if one man brings an action at law against another, and a bill is brought to be relieved either against a penalty, or to stay proceedings at law, or some equitable circumstances, of which the party cannot have the benefit at law. In such case the plaintiff in equity may move for an injunction either upon an attachment, or praying a dedimus, or praying a farther time to answer; for it being suggested in the bill that the suit is against conscience, if the defendant is in contempt for not answering, or prays time to answer, it is contrary to conscience to proceed at law in the mean time; and therefore an injunction is granted of course: but this injunction only stays execution touching the matter in question; and there is always a clause giving liberty to call for a plea to proceed to trial, and for want of it to obtain judgment; but execution is stayed till answer, or farther order. 3 Bac. Abr. 173.

When a bill in chancery is filed in the office of the six clerks, if an injunction is prayed therein, it may be had, at various stages of the cause, according to the circumstances of the case. If the bill is to stay execution upon an oppressive judgment, and the defendant does not put in his answer within the time allowed by the rules of the court, an injunction will issue of course; and when the answer comes in, the injunction can only be continued upon a sufficient ground appearing from the answer itself. But if an injunction is wanted to stay waste, or other injuries of an equally unjust nature, then upon the filing of the bill, and a proper case supported by affidavits, the court will grant an injunction immediately; to continue till the defendant has put in his answer, and till the court shall make some further order concerning it; and when the answer comes in whether it shall then be dissolved, or continued till the hearing of the cause, is determined by the court upon argument, drawn from considering the answer and affidavits together. 3 Bla. 443.

The methods of dissolving injunctions are various; when the answer comes in, and the party has cleared his contempt by paying the costs of the attachment, if there is one, he obtains an order to dissolve nisi, and serves it on the plaintiff's clerk in court: this order takes notice of the defendant's having fully answered the bill, and thereby denied the whole equity thereof, and being regularly served, the plaintiff must shew cause at the day; or the defendant's counsel, where there is no probability of shewing cause, may move to make the order absolute, unless cause, sitting the court. 3 Bac. Abr. 177.

If the plaintiff who has an injunction die pending the suit, in strictness the whole proceedings are abated, and the injunction with them; but even in this case the party shall not take out execution without special leave of the court; he must move the court for the plaintiff to revive his suit within a limited time, or the injunction to stand dissolved; and as this is never denied, so if the suit is not revived, the party takes out execution. There are some instances where a plaintiff may move to revive his injunction; but as that rarely happens, so it is rarely granted, especially where the injunction has been before dissolved; but where a bill is dismissed, the injunction and every thing else are gone, and execution may be taken out the next day. 3 Bac. Abr. 178.

INJURY, a wrong or damage to a man's person or goods. The law will suffer a private injury rather than a public evil; and the act of God or the law does injury to none. 4 Rep. 124.

INK. There are two principal kinds of ink, writing and printing ink.

Writing-ink. When to an infusion of gall-nuts some solution of sulphate of iron (green copperas) is added, a very dark-blue precipitate takes place. This precipitate is the gallic acid of the galls united to the iron of the green vitriol, forming gallat of iron, which is the basis of writing-ink. If galls and sulphate of iron only were used, the precipitate would fall down, leaving the water colourless; and in order to keep it suspended in the water, forming a permanently black, or rather very dark blue fluid, gum arabic is added, which, by its viscid nature, prevents the precipitate from falling down.

Various receipts have been given for the composition of writing-ink, but very few have been founded upon a knowledge of its real nature. The receipt given by M. Ribancourt is as follows: Take eight ounces of Aleppo galls, in coarse powder; four ounces of logwood, in thin chips; four ounces of sulphate of iron (green copperas); three ounces of gum arabic, in powder; one ounce of sulphate of copper (blue vitriol); and one ounce of sugar-candy. Boil the galls and logwood together in twelve pounds of water for one hour, or till half the liquid has been evaporated. Strain the decoction through a hair sieve, or linen cloth, and then add the other ingredients. Stir the mixture till the whole is dissolved, more especially the gum; after which leave it to subside for 24 hours. Then decant the ink, and preserve it in bottles of glass or stone ware, well corked.

The following will also make a good ink: To one quart of soft water add four ounces of galls, one ounce of copperas roughly bruised, and two ounces of gum arabic. Let the whole be kept near the fire a few days, and occasionally well shaken.

Red writing-ink is made in the following manner: Take of the raspings of Brazil wood a quarter of a pound, and infuse them two or three days in vinegar. Boil the infusion for an hour over a gentle fire, and afterwards filtre it while hot. Put it again over the fire, and dissolve in it, first, half an ounce of gum arabic; and afterwards of alum and white sugar, each half an ounce.

Printing-ink is a black paint, composed of lamp-black and linseed or suet oil boiled, so as to acquire considerable consistence and tenacity. The art of preparing it is kept a secret; but the obtaining good lamp-black appears to be the chief difficulty in making it.

The ink used by copper-plate printers differs from the last only in the oil not being so much boiled, and the black which is used being Frankfort black.

Sympathetic inks are such as do not appear after they are written with, but which may be made to appear at pleasure, by certain means to be used for that purpose. A variety of substances have been used for this purpose. We shall describe the best of them.

1. Dissolve some sugar of lead in water, and write with the solution. When dry, no writing will be visible. When you want to make it appear, wet the paper with a solution of alkaline sulphuret (liver of sulphur), and the letters will immediately appear of a brown colour. Even exposing the writing to the vapours of these solutions will render it apparent.

2. Write with a solution of gold in aqua regia, and let the paper dry gently in the shade. Nothing will appear; but draw a sponge over it wetted with a solution of tin in aqua regia, the writing will immediately appear of a purple colour.

3. Write with an infusion of galls, and when you wish the writing to appear, dip it into a solution of green vitriol; the letters will appear black.

4. Write with diluted sulphuric acid, and

nothing will be visible. To render it so, hold it to the fire, and the letters will instantly appear black.

5. Juice of lemons, or onions, a solution of sal ammoniac, green vitriol, &c. will answer the same purpose, though not so easily, nor with so little heat.

6. Green sympathetic ink. Dissolve cobalt in nitromuriatic acid, and write with the solution. The letters will be invisible till held to the fire, when they will appear green, and will disappear completely again when removed into the cold. In this manner they may be made to appear and disappear at pleasure.

A very pleasant experiment of this kind is to make a drawing representing a winter scene, in which the trees appear void of leaves, and to put the leaves on with this sympathetic ink; then, upon holding the drawing near to the fire, the leaves will begin to appear in all the verdure of spring, and will very much surprise those who are not in the secret.

7. Blue sympathetic ink. Dissolve cobalt in nitric acid; precipitate the cobalt by potass; dissolve this precipitated oxide of cobalt in acetic acid, and add to the solution one-eighth of common salt. This will form a sympathetic ink, that, when cold, will be invisible, but will appear blue by heat.

INK, *removing stains of.* The stains of ink on cloth, paper, or wood, may be removed by almost all acids; but those acids are to be preferred which are least likely to injure the texture of the stained substance. The muriatic acid, diluted with five or six times its weight of water, may be applied to the spot, and, after a minute or two, may be washed off, repeating the application as often as may be found necessary. But the vegetable acids are attended with less risk, and are equally effectual. A solution of the oxalic, citric (acid of lemons), or tartareous acids, in water, may be applied to the most delicate fabrics without any danger of injuring them; and the same solutions will discharge writing, but not printing-ink. Hence they may be employed in cleaning books which have been defaced by writing on the margin, without impairing the text. Lemon-juice, and the juice of sorrel, will also remove ink-stains, but not so easily as the concrete acid of lemons, or citric acid.

INNS AND INNKEEPERS. Common inns were instituted for passengers; and the duty of innkeepers extends chiefly to the entertaining and harbouring of travellers, finding them victuals and lodging, and securing the goods and effects of their guests; and therefore if one who keeps a common inn refuses either to receive a traveller as a guest into his house, or to find him victuals or lodging, upon his tendering a reasonable price for the same, he is not only liable to render damages for the injury in an action on the case, at the suit of the party grieved, but also may be indicted and fined at the suit of the king. Dyer, 158.

In return for such responsibility the law allows him to retain the horse of his guest until paid for his keep; but he cannot retain such horse for the bill of the owner, although he may retain his goods for such bill; neither can he detain one horse for the food of another. 1 Bulst. 207, 217.

An innkeeper, however, is not bound to receive the horse, unless the master lodge there also. 2 Brown, 254.

Neither is a landlord bound to furnish provisions unless paid beforehand. 9 Co. 87.

If an innkeeper makes out unreasonable bills, he may be indicted for extortion; and if either he or any of his servants knowingly sell bad wine or bad provisions, they will be responsible in an action of deceit.

Any person may set up a new inn, unless it is inconvenient to the public, in respect of its situation, or to its increasing the number of inns, not only to the prejudice of the public, but also to the hindrance and prejudice of other antient and well-governed inns: for the keeping of an inn is no franchise, but a lawful trade, open to every subject, and therefore there is no need of any licence from the king for that purpose. 2 Roll. Abr. 84.

An innkeeper is distinguished from other trades in that he cannot be a bankrupt; for though he buys provisions to be spent in his house, yet he does not properly sell them, but utter them at such rates as he thinks reasonable; and the attendance of his servants, furniture of his house, &c. are to be considered; and the statutes of bankruptcy only mention merchants that use to buy and sell in gross, or buy retail, and such as get their living by buying and selling; but the contracts with innkeepers are not for any commodities in specie, but they are contracts for house-room, trouble, attendance, lodging, and necessaries, and therefore cannot come within the design of such words, since there is no trade carried on by buying and bartering commodities. 1 Jones, 437.

But where an innkeeper is a chapman also, and buys and sells, he may, on that account, be a bankrupt, though not barely as an innkeeper, and this has been frequently seen. 7 Vin. Abr. 57.

Innkeepers are clearly chargeable for the goods of guests stolen or lost out of their inns, and this without any contract or agreement for that purpose; for the law makes them liable in respect of the reward, as also in respect of their being places appointed and allowed by law, for the benefit and security of traders and travellers. Dyer, 266.

But if a person comes to an innkeeper, and desires to be entertained by him, which the innkeeper refuses, because his house is already full; whereupon the party says he will shift among the rest of his guests, and there he is robbed, the host shall not be charged. Dyer, 158.

If a man comes to a common inn to harbour, and desires that his horse may be put to grass, and the host put him to grass accordingly, and the horse is stolen, the host shall not be charged; because by law the host is not bound to answer for any thing out of his inn, but only for those that are infra hospitium. 8 Co. 32 b.

Innkeepers may detain the person of the guest who eats, or the horse which eats, till payment, and this he may do without any agreement for that purpose; for men that get their livelihood by entertainment of others, cannot annex such disobliging conditions, that they should retain the party's property in case of non-payment, nor make such disadvantageous and impudent a supposition, that they shall not be paid; and therefore the law annexed such a condition without the agreement of the parties. Roll. Abr. 85.

By the custom of London and Exeter, if a man commits a horse to a hostler, and he eats out the price of his head, the hostler may take him as his own, upon the reasonable appraisement of four of his neighbours; but the innkeeper has no power to sell the horse, by the general custom of the whole kingdom. Moor. 876. 3 Bulst. 271.

But it has been held, that though an innkeeper in London may, after long keeping, have the horse appraised, and sell him; yet when he has, in such case, had him appraised, he cannot justify the taking him to himself, at the price it was appraised at. 1 Vin. Abr. 233.

INNS OF COURT, are so called, because the students therein study the law, to enable them to practise in the courts at Westminster, or elsewhere; and also because they use all other gentle exercises, as may render them better qualified to serve the king in his court. Fortesq. c. 49.

INNOMINATA OSSA. See ANATOMY.

INNUENDO, is a word used in declarations and law proceedings, to ascertain a person or thing which was named before; as to say he (innuendo the plaintiff) did so and so, when there was mention before of another person.

Innuendo may serve for an explanation where there is precedent matter, but never for a new charge; it may apply what is already expressed, but cannot add or enlarge the importance of it. 2 Salk. 513.

INOCULATION. See MEDICINE.

INOCULATION, or *Budding*. See GRAFTING.

INOLITHUS, in mineralogy, a stone consisting of carbonate of lime, carbonic acid gas, and a little iron; entirely soluble in nitric acid with effervescence; fibrous, parasitic, soft, lightish, breaking into indeterminate fragments. There are several species: of the filamentosius there are three varieties; the satin spar, so called from its rich satiny lustre, is found in Russia, Poland, Germany, Saxony, and Bohemia, with the fibres straight and a little curved. It is found also about a mile from Alston in Cumberland, washed by the river Tyne, near the level of its bed; colour white, with sometimes a rosy tinge from a diluted oxide of iron, and transmits light from the edges, or in thinner pieces: fracture in the direction of the striæ fibrous, straight or curved; specific gravity about 2.71, contains carbonic acid 47, carbonate of lime 50, water of crystallization 2, and a small portion of iron.

INORDINATE PROPORTION, is where there are three magnitudes in one rank, and three others proportional to them in another, and you compare them in a different order. Thus suppose the numbers in one rank to be 2, 3, 9; and those of the other rank 8, 24, 36; which are compared in a different order, viz. 2 : 3 : : 24 : 36; and 3 : 9 : : 8 : 24. Then rejecting the mean terms of each rank, you conclude 2 : 9 : : 8 : 36.

INQUEST, in law, signifies an enquiry made by a jury, in a civil or criminal cause, by examining witnesses. There is also an inquest of office, used for the satisfaction of the judges, and sometimes to make an enquiry whether a criminal is a lunatic or not; upon which inquest, if it is found that the criminal only feigns himself to be a lunatic, and at the same time refuses to plead, he may be dealt with as one standing mute. Where a person is attainted of felony, and escapes, and afterwards, on being retaken, denies that he is the same man, inquest must be made into the identity of the person by a jury, before he can be executed.

INQUISITION, in law, a manner of proceeding by way of search or examination used on the king's behalf, in cases of outlawry, treason, felony, self-murder, &c. to discover lands, goods, and the like, forfeited to the crown. Inquisition is also had upon extents of lands, tenements, &c. writs of elegit, and where judgment being had by default, damages and costs are recovered.

INQUISITION, in the church of Rome, a tribunal in several Roman-catholic countries, erected by the popes for the examination and punishment of heretics.

This court was founded in the 12th century by father Dominic and his followers, who were sent by pope Innocent III. with orders to excite the catholic princes and people to extirpate heretics, to search into their number and quality, and to transmit a faithful account thereof to Rome. Hence they were called inquisitors; and this gave birth to the formidable tribunal of the inquisition, which was received in all Italy, and the dominions of Spain, except the kingdom of Naples, and the Low-countries. See ACT OF FAITH.

INROLLMENT, in law, is the registering, recording, or entering in the rolls of the chancery, king's-bench, common-pleas, or exchequer, or by the clerk of the peace in the records of the quarter-sessions, of any lawful act; a statute or recognizance acknowledges a deed of bargain and sale of lands, and the like; but the inrolling a deed does not make it a record, though it thereby becomes a deed recorded; for there is a difference between a matter of record, and a thing recorded to be kept in memory; a record being the entry in parchment of judicial matters controverted in a court of record, and whereof the court takes notice, whereas an inrollment of a deed is a private act of the parties concerned, of which the court takes no cognizance at the time of doing it, although the court permits it. 2 Lill. Abr. c. 9.

By stat. 27 H. VIII. c. 16. no lands shall pass, whereby any estate of inheritance or freehold shall take effect, or any use thereof be made, by reason only of any bargain and sale thereof, except the bargain and sale is made by writing indented, sealed, and within six months inrolled in one of the king's courts of record at Westminster; or else within the county where the lands lie, before the clerk of the peace, and one or more justices.

But by 5 Eliz. c. 26, in the counties palatine, they may be inrolled at the respective courts there, or at the assizes.

Every deed before it is inrolled is to be acknowledged to be the deed of the party, before a master of chancery, or a judge of the court wherein it is inrolled, which is the officer's warrant for inrolling the same; and the inrollment of a deed, if it is acknowledged by the grantor, will be a good proof of the deed itself upon trial. 2 Lill. Abr. 69.

But a deed may be inrolled without the examination of the party himself; for it is sufficient if oath is made of the execution. If two are parties, and the deed is acknowledged by one, the other is bound by it. And if a man lives abroad, and would pass lands here in England, a nominal person may be joined with him in the deed, who may acknowledge it here, and it will be binding. 1 Salk. 389.

INSCRIBED, in geometry. A figure is said to be inscribed in another when all its angles touch the sides or planes of the other figure.

INSECTS. See ENTOMOLOGY.

INSOLATION, in chemistry, a term made use of to denote an exposure to the sun, to promote the chemical action of one substance upon another.

INSTALLMENT, the instating or establishing a person in some dignity. This word is chiefly used for the induction of a dean, prebendary, or other ecclesiastical dignitary, into the possession of his stall, or other proper seat in the cathedral to which he belongs. It is also used for the ceremony whereby the knights of the garter are placed in their rank in the chapel of St. George at Windsor, and on many other like occasions. It is sometimes termed installation.

INSTITUTES, in literary history, a book containing the elements of the Roman law, and constituting the last part of the civil law. The institutes are divided into four books, and contain an abridgment of the whole body of the civil law, being designed for the use of students.

INSTITUTION, in general, signifies the establishing or founding something.

In the canon and common law it signifies the investing a clerk with the spiritualities of a rectory, &c. which is done by the bishop, who uses the formula, "I institute you rector of such a church, with cure of souls, and receive your care and mine." This makes him a complete parson as to spirituality, but not as to temporality, which depends on induction. The term institutions is also used, in a literary sense, for a book containing the elements of any art or science: such are institutions of medicine, institutions of rhetoric, &c.

INSTRUMENT, in law, some public act or authentic deed, by which any truth is made apparent, or any right or title established in a court of justice. See DEED.

INSTRUMENTS, in music, are either played on by means of wind, as the organ, &c.; or by strings, as the violin, &c.

INSTRUMENTS, ASTRONOMICAL. We shall, under the word OBSERVATORY, give an account of the several instruments made use of in practical astronomy.

INSTRUMENTS, *mathematical*. A pocket case of mathematical instruments contains the following particulars, viz. 1. A pair of plain compasses. 2. A pair of drawing compasses, with its several parts. 3. A drawing-pen and pointer. 4. A protractor, in form of a semicircle, or sometimes of a parallelogram. 5. A parallel ruler. 6. A plain scale. 7. A sector, besides the black-lead pencil for drawing lines. The general uses of the above instruments are as follow: see Plate Mathematical Instruments.

I. *Of the plain compasses*, Fig. 1. The use of the common or plain compasses is, (1.) to draw a blank line A B, by the edge of a ruler, through any given point or points C D, &c. (2.) Take any extent or length between the points of the compasses, and to set it off, or apply it successively upon any line, as from C to D, fig. 2. (3.) To take any proposed line C D between the points, and, by applying it to the proper scale, to find its length. (4.) To set off equal distances upon a given line, by making a dot with the point at each, through which to draw parallel lines. (5.) To draw any blank circle, intersecting arches, &c. (6.) To lay off an angle of a given quantity upon an arch of a circle from the line of chords, &c. (7.) To measure any arch or angle, upon the chords, &c. (8.) To construct any proposed figure, in plotting or making plans, &c. by setting off the quantity of the sides and angles from proper scales. In short, the use of the compasses occurs in every branch of practical mathematics.

II. *Of the drawing-compasses*. These compasses are chiefly designed for drawing circles, and circular arches; and it is often necessary they should be drawn with different materials; and therefore this pair of compasses has, in one of its legs, a triangular socket, and screw, to receive and fasten the following parts or points for that purpose, viz. (1.) A steel point, which being fixed in the socket, makes the compasses then but a plain pair, and has all the same uses as just now described in drawing blank circles, setting off lines, &c. (2.) A port-crayon with a black-lead pencil, cut to a fine point, for drawing lines that may be easily rubbed out again, if not right. A piece of slate-pencil may also be used in this part for drawing on slate. (3.) The dotting-point, or dotting-pen, with a small rowel, or indented wheel at the end, moving very freely; and receiving ink from the brass pen over it, communicates the same in equal and regular dots upon the paper, where dotted lines are chosen. (4.) The steel pen or point, for drawing and describing black lines with ink; for this purpose the two parts or sides of the pen are opened or closed with an adjusting screw, that the line drawn may be as fine or as coarse as you please.

In the port-crayon, dotter, and steel pen, there is a joint, by which you can set the lower part always perpendicular to the paper, which is necessary for drawing a line well, in every extent or opening of the compasses.

In some of the better sort of instruments, these points slide into the socket, and are kept tight by a spring on the inside, that is not seen.

The steel point is sometimes made with a joint, and furnished with a fine spring and screw; by which, when you have opened the compasses nearly to the extent required, you can, by turning the screw, move the point to the true extent as it were, to a hair's breadth; which is the reason these are called hair-compasses.

The common compasses, at large, are not altogether so well adapted for small drawings; and therefore a small sort called bows, are contrived to answer all such purposes; they consist only of a steel point and drawing-pen, with a joint, and of a small length, so that very small circles may be nicely drawn with them, as they are to be conveniently moved and turned about in the hand, by a short stem or shaft.

III. *Of the drawing pen and pencil.* The drawing-pen is only the common steel pen at the end of a brass rod, or shaft, of a convenient length, to be held in the hand for drawing all kinds of straight black lines by the edge of a rule. The shaft or handle has a screw in the middle part; and, when unscrewed, there is a fine steel round pin or point, by which you make as nice a mark or dot upon the paper as you please, for terminating your lines in curious draughts.

The black-lead pencil, if good, is of frequent use for drawing straight lines, and for supplying the place of the drawing-pen, where lines of ink are not necessary; it is also often substituted for the common pen in writing, figuring, &c. Because in all cases, if what be drawn with it be not right, or does not please, it may be very easily rubbed out with a piece of crumb-bread, and the whole new-drawn.

IV. *Of the protractor.* The protractor is a semicircle of brass, A D B, divided into 180 degrees, and numbered each way from end to end of the semicircle by 10°, 20°, 30°, &c. The central line is the external edge of the protractor's diameter, or straight side, sloped down to the under side, and is generally called a fiducial edge; in the middle of which is a small line or fine notch in the very edge, for the centre of the protractor. The uses of the protractor are two: (1.) To measure any angle proposed. (2.) To lay down any angle required.

For example: suppose it required to find what number of degrees are contained in the angle ACB (fig. 4); you place the centre of the protractor upon the angular point C, and the fiducial edge exactly upon the line C A; then observe what number of degrees the line C B cuts upon the graduated limb of the protractor, and that will be the measure of the angle A C B as required.

Secondly, suppose it required to protract or lay off from the line A C, an angle A C B, equal to 35 degrees. To do this, you place the centre of the protractor upon the given point C, and the straight edge upon A C very exactly; then make a fine point or dot at 35 degrees on the limb at B, and the protractor being removed, you draw through B the straight line C B, and it will make the angle A C B required.

Protractors in form of a parallelogram, or long square, as *a* E F *b* fig. 3, are usually made in ivory or brass; are more exact than the common semicircular ones, for angles to 40 or 50 degrees, because at and about each end, the divisions (being farther from the centre) are larger.

V. *Of the parallel ruler.* The parallel ruler is so called, because as it consists of two straight rules, connected together by two brass bars, yet so as to admit a very free motion to each: the one ruler must always move parallel-wise to the other, that is, one rule will be every where equidistant from the other, and by this means it becomes naturally fitted for drawing one or more lines parallel to, or equally distant from, any line proposed. The manner of doing which is thus:

Let it be required to draw a straight line parallel to a given line A B, and at the distance AC, from it. (fig. 5.) First open the rulers to a greater distance than A C, and place the edge of the rulers exactly on the line A B; then holding the other rule (or side) firmly on the paper, you move the upper rule down from A to the point C, by which (holding it fast) you draw the line C D, which will be parallel to the given line A B as required.

Many very useful problems in the mathematics are performed by this instrument, of which the following are examples.

Let it be required to find a fourth proportional to three right lines given, A B, B C, and A D (fig. 6). To do this, draw the lines A C, A E, making any angle at pleasure. Upon A C with the compasses set off the lines A B and B C; and upon A E set of the line A D; join D B, and parallel to it draw E C, then will D E be the fourth proportional required. For A B : B C :: A D : D E.

Again, suppose it required to divide any line, A B, as another line A C is divided (fig. 7). To do this, join the extremities of each line C B, and parallel to C B draw E I, E H D G, through the given points D E F in the line A C; and by these lines the line A B will be divided exactly similar to the line A C.

The parallel ruler is seldom put into a case of instruments, but those of the larger and better sort; being generally sold by itself of various sizes, from 6 inches to 2 feet in length.

Of the plain scale. The lines generally drawn on the plain scale, are these following:

	Marked
I. Lines of equal parts.	E. P.
II. ——— Chords.	Cho.
III. ——— Rhumbs.	Ru.
IV. ——— Sines.	Sin.
V. ——— Tangents.	Tan.
VI. ——— Secants.	Sec.
VII. ——— Half-Tangents.	S. T.
VIII. ——— Longitude.	Long.
IX. ——— Latitude.	Lat.
X. ——— Hours.	Ho.
XI. ——— Inclinations.	In. Mer.

Of the lines of equal parts. Lines of equal parts are of two sorts, viz. simply divided, and diagonally divided, Plate 5.

1. Simply divided. Draw three lines parallel to one another, at unequal distances (fig. 8), and of any convenient length; divide this length into what number of equal parts is thought necessary, allowing some certain number of these parts to an inch, such as 2, $2\frac{1}{2}$, 3, $3\frac{1}{2}$, 4, $4\frac{1}{2}$, &c. which divisions distinguish by lines drawn across the three parallels. Divide the left-hand division into 10 equal parts, which distinguish by lines drawn across the lower parallels only; but for distinction's sake, let the fifth division be somewhat longer than the others: and it may not be inconvenient to divide the same left hand division into 12 equal parts, which are laid down on the upper parallel line, having the third, sixth, and ninth divisions distinguished by longer strokes than the rest, whereof that at the sixth division make the longest.

There are, for the most part, several of these simply divided scales put on rulers, one above the other, with numbers on the left hand, shewing in each scale, how many equal parts an inch is divided into; such as 20, 25, 30, 35, 40, 45, &c. and are severally used, as the plan to be expressed should be larger or smaller.

The use of these lines of equal parts, is to lay down any line expressed by a number of two places or denominations, whether decimally or duodecimally divided; as leagues, miles, chains, poles, yards, feet, inches, &c. and their tenth parts, or twelfth parts; thus, if each of the divisions be reckoned 1, as 1 league, mile, chain, &c. then each of the subdivisions will express $\frac{1}{10}$ part thereof; and if each of the large divisions be called 10, then each small one will be 1; and if the large divisions be 100, then each small one will be 10, &c.

Therefore to lay off a line $8\frac{7}{10}$, 87, or 870 parts, let them be leagues, miles, chains, &c. set one point of the compasses on the 8th of the large divisions, counting from the left hand towards the right, and open the compasses, till the other point falls on the 7th of the small divisions, counting from the right hand towards the left, then are the compasses opened to express a line of $8\frac{7}{10}$ 87, or 870 leagues, miles, chains, &c. and bears such proportion in the plan, as the line measured does to the thing represented.

But if a length of feet and inches was to be expressed, the same large divisions may represent the feet, but the inches must be taken from the upper part of the first division, which (as before noted) is divided into twelve equal parts.

Thus if a line of 7 feet 5 inches was to be laid down, set one point of the compasses on the fifth division among the twelve, counting from the right hand towards the left, and extend the other to 7, among the large divisions: and that distance laid down in the plan, shall express a line of 7 feet 5 inches; and the like is to be understood of any other dimensions.

2. Diagonally divided. Draw eleven lines parallel to each other, and at equal distances; divide the upper of these lines into such a number of equal parts, as the scale to be expressed is intended to contain; and from each of these divisions draw perpendiculars through the eleven parallels (fig. 9): subdivide the first of these divisions into 10 equal parts, both in the upper and lower lines; then each of these subdivisions may be also subdivided into ten equal parts, by drawing diagonal lines; viz. from the 10th below, to the ninth above; from the ninth below to the eighth above; from the eighth below to the seventh above, &c. till from the first below to the 0th above, so that by these means one of the primary divisions on the scale will be divided into 100 equal parts.

There are generally two diagonal scales laid on the same plane or face of the ruler, one being commonly half the other (fig. 9).

The use of the diagonal scale is much the same with the simple scale; all the difference is, that a plan may be laid down more accurately by it; because in this, a line may be taken of three denominations, whereas from the former, only two could be taken.

Now from this construction it is plain, if each of the primary divisions represent 1, each of the first subdivisions will express $\frac{1}{10}$ of 1; and each of the second subdivisions (which are taken on the diagonal lines, counting from the top downwards) will express $\frac{1}{10}$ of the former subdivisions or a 100th of the primary divisions; and if each of the primary divisions express 10, then each of the first subdivisions will express 1, and each of the 2d, $\frac{1}{10}$; and if each of the primary divisions represent 100, then each of the first subdivisions will be 10, and each of the 2d will be 1, &c.

Therefore to lay down a line, whose length is expressed by 347, 34 $\frac{7}{10}$ or 3 $\frac{47}{100}$, whether leagues, miles, chains, &c.

On the diagonal line, joined to the 4th of the first subdivisions, count 7 downwards, reckoning the distance of each parallel 1; there set one point of the compasses, and extend the other, till it falls on the intersection of the third primary division with the same parallel in which the other foot rests, and the compasses will then be opened to express a line of 347, 34 $\frac{7}{10}$, or 3$\frac{47}{100}$, &c.

Those who have frequent occasion to use scales, perhaps will find, that a ruler with the 20 following scales on it, viz. 10 on each face, will suit more purposes than any set of simply divided scales hitherto made public, on one ruler.

One Side.—The divisions to an inch.
10, 11, 12, 13½, 15, 16½, 18, 20, 22, 25.

Other Side—The divisions to an inch.
28, 32, 36, 40, 45, 50, 60, 70, 85, 100.

The left-hand primary division, to be divided into 10 and 12 and 8 parts; for these subdivisions are of great use in drawing the parts of a fortress, and of a piece of cannon.

It will here be convenient to shew, how any plan expressed by right lines and angles, may be delineated by the scales of equal parts, and the protractor. Suppose three adjacent things in any right-lined triangle being given, to form the plan thereof.

Example. Let ABC (fig. 10,) be a triangular field, the side AB = 327 yards; AC = 208 yards; and the angle at A = 44½ degrees.

Construction. Draw a line A B at pleasure; then from the diagonal scale take 327 between the points of the compasses, and lay it from A to B; set the centre of the protractor to the point A, lay off 44½ degrees, and by that mark draw A C; take with the compasses from the same scale 208, lay it from A to C, and join C B; so shall the parts of the triangle A B C, in the plan, bear the same proportion to each other, as the real parts in the field do.

The side C B may be measured on the same scale from which the sides A B, A C, were taken; and the angles at B and C may be measured by applying the protractor to them.

If two angles and the side contained between them were given.

Draw a line to express the side (as before); at the ends of that line, point off the angles, as observed in the field; lines drawn from the ends of the given line through those marks, shall form a triangle similar to that of the field.

Five adjacent things, sides and angles, in a right-lined quadrilateral, being given, to lay down the plan thereof, fig. 11.

Example. Given ∠ A = 70°; AB = 215 links; ∠ B = 115°; BC = 596 links; ∠ C = 114°.

Construction. Draw A D at pleasure; from A draw A B, so as to make with A D an angle of 70°: make AB=215 (taken from the scales); from B, draw B C, to make with A B an angle of 115°; make B C = 596; from C, draw C D, to make with C B an angle of 114°; and by the intersection of C D with A D, a quadrilateral will be formed similar to the figure in which such measures could be taken as are expressed in the example.

If three of the things were sides, the plan might be formed with equal ease.

Following the same method, a figure of many more sides may be delineated; and in this manner, or some other like to it, surveyors make their plans or surveys.

The remaining lines of the plain scale are thus constructed.

Describe a circumference with any convenient radius, and draw the diameters fig. 12 A B, D E, at right angles to each other; continue B A at pleasure towards F; through D, draw D G parallel to B F; and draw the chords B D, B E, A D, A E. Circumscribe the circle with the square H M N, whose sides H M, M N, shall be parallel to A B, E D.

1. *To construct the line of chords.* Divide the arc A D into 90 equal parts: mark the 10th divisions with the figures 10, 20, 30, 40, 50, 60, 70, 80, 90; on D, as a centre, with the compasses, transfer the several divisions of the quadrantal arc, to the chord A D, which marked with the figures corresponding, will become a line of chords.

Note. In the construction of this, and the following scales, only the primary divisions are drawn; the intermediate ones are omitted, that the figure may not appear too much crowded.

2. *The line of rhumbs.* Divide the arc B E into 8 equal parts, which mark with the figures 1, 2, 3, 4, 5, 6, 7, 8, and divide each of those parts into quarters; on B, as a centre, transfer the divisions of the arc to the chord B E, which marked with the corresponding figures, will be a line of rhumbs.

3. *The line of sines.* Through each of the divisions of the arc A D, draw right lines parallel to the radius A C; and C D will be divided into a line of sines which are to be numbered from C to D for the right sines, and from D to C for the versed sines. The versed sines may be continued to 180 degrees by laying the divisions of the radius C D, from C to E.

4. *The line of tangents.* A ruler on C, and the several divisions of the arc A D, will intersect the line D G, which will become a line of tangents, and is to be figured from D to G, with 10, 20, 30, 40, &c.

5. *The line of secants.* The distances from the centre C to the divisions on the line of tangents being transferred to the line C F from the centre C, will give the divisions of the line of secants; which must be numbered from A towards F, with 10, 20, 30, &c.

6. *The line of half-tangents (or the tangents of half the arcs).* A ruler on E, and the several divisions of the arc A D, will intersect the radius C A, in the divisions of the semi or half tangents; mark these with the corresponding figures of the arc A D.

The semitangents on the plane scales are generally continued as far as the length of the ruler they are laid on will admit; the divisions beyond 90° are found by dividing the arc A E like the arc A D, then laying a ruler by E and these divisions of the arc A E, the divisions of the semitangents above 90 degrees will be obtained on the line C A continued.

7. *The line of longitude.* Divide A H into 60 equal parts; through each of these divisions, parallels to the radius A C, will intersect the arc A E, in as many points; from E as a centre, the divisions of the arc E A, being transferred to the chord E A, will give the divisions of the line of longitude.

The points thus found on the quadrantal arc, taken from A to E, belong to the sines of the equally increasing sexagenary parts of the radius; and those arcs reckoned from E, belong to the cosines of those sexagenary parts.

8. *The line of latitude.* A ruler on A, and the several divisions of the sines on C D, will intersect the arc B D, in as many points; on B as a centre, transfer the intersections of the arc B D, to the right line B D; number the divisions from B to D, with 10, 20, 30, &c. to 90; and B D will be a line of latitude.

9. *The line of hours* Bisect the quadrantal arcs B D, B E, in *a*, *b*; divide the quadrantal arc *ab* into 6 equal parts (which gives 15 degrees for each hour); and each of these into 4 others (which will give the quarters). A ruler on C, and the several divisions of the arc *ab*, will intersect the line M N in the hour, &c. points, which are to be marked as in the figure.

10. *The line of inclinations of meridians.* Bisect the arc E A in *c*; divide the quadrantal arc *bc* into 90 equal parts; lay a ruler on C and the several divisions of the arc *bc*, and the intersections of the line H M will be the divisions of a line of inclinations of meridians.

Of the sector. A sector is a figure formed by two radii of a circle, and that part of the circumference comprehended between the two radii.

The instrument called a sector, consists of two flat rulers moveable round an axis or joint; and from the centre of this joint several scales are drawn on the faces of the rulers.

The two rulers are called legs, and represent the radii of a circle; and the middle of the joint expresses the centre.

The scales generally put on sectors, may be distinguished into single, and double.

The single scales are such as are commonly put on plain scales, and from whence dimensions or distances are taken, as have been already directed.

The double scales are those which proceed from the centre; each scale is laid twice on the same face of the instrument, viz. once on each leg: from these scales, dimensions or distances are to be taken, when the legs of the instrument are in an angular position, as will be shewn hereafter.

The SCALES *commonly put on the best* SECTORS, *are*

	No.		Scale		Mark
Single	1	a line of	Inches, each Inch divided into 8 and 10 parts.		
	2		Decimals, containing 100 parts.		
	3		Chords,	marked	Cho.
	4		Sines,		Sin.
	5		Tangents,		Tang.
	6		Rhumbs,		Rum.
	7		Latitude,		Lat.
	8		Hours,		Hou.
	9		Longitude,		Lon.
	10		Inclin. Merid.		In. Me.
	11		the Logarithms of Numbers,		Num.
	12		the Logarithms of Sines,		Sin.
	13		the Logarithms of Versed Sines,		V. Sin.
	14		the Logarithms of Tangents,		Tan.
Double	1	a line of	Lines, or of equal parts,	marked	Lin.
	2		Chords,		Cho.
	3		Sines,		Sin.
	4		Tangents to 45°		Tan.
	5		Secants,		Sec.
	6		Tangents above 45°		Tan.
	7		Polygons,		Pol.

The scales of lines, chords, sines, tangents, rhumbs, latitudes, hours, longitude, incl. merid. may be used, whether the instrument is shut or open, each of these scales being contained on one of the legs only. The scales of inches, decimals, log. numbers, log. sines, log. versed sines, and log. tangents, are to be used with the sector quite opened, part of each scale lying on both legs.

The double scales of lines, chords, sines, and lower tangents, or tangents under 45 degrees, are all of the same radius or length; they begin at the centre of the instrument, and are terminated near the other extremity of each leg; viz. the lines at the division 10, the chords at 60, the sines at 90, and the tangents at 45; the remainder of the tangents, or those above 45 degrees, are on other scales beginning at $\frac{1}{4}$ of the length of the former, counted from the centre, where they are marked with 45, and run to about 76°. The secants also begin at the same distance from the centre, where they are marked with 0, and are from thence continued to as many degrees as the length of the sector will allow, which is about 75 degrees.

Each double scale, one being on each leg and proceeding from the centre, make an angle; and in an equal angular position are all the double scales, whether of lines, or of chords, or of sines, or of tangents to 45 degrees.

And the angles made by the scales of upper tangents, and of secants, are also equal; and sometimes these angles are made equal to those made by the other double scales.

The scales of polygons are put near the inner edge of the legs: their beginning is not so far removed from the centre, as the 60 on the chords is: where these scales begin, they are marked with 4, and from thence are figured backwards, or towards the centre, to 12.

From this disposition of the double scales, it is plain, that those angles which were equal to each other, while the legs of the sector were close, will still continue to be equal, although the sector be opened to any distance it will admit of.

We shall now illustrate the nature of this instrument by examples.

Let CL, CL, (fig. 13) be the two lines of lines upon the sector, opened to an angle LCL; join the divisions 4 and 4, 7 and 7, 10 and 10, by the dotted lines *a*, *b*, *c*, *d*, L L. Then by the nature of similar triangles, it is C L to C *b*, as L L to *a b*; and CL to C *d*, as L L to *c d*; and therefore *a b* is the same part of L L as C *b* is of C L. Consequently, if L L be 10, then *a b* will be 4, and *c d* will be 7 of the same parts.

And hence, though the lateral scale C L be fixed, yet a parallel scale LL, is obtainable at pleasure; and therefore though the lateral radius is of a determined length in the lines of chords, sines, tangents and secants, yet the parallel radius may be had of any size you want, by means of the sector, as far as its length will admit; and all the parallel sines &c. peculiar to it; as will be evident by the following examples in each pair of lines.

Ex. 1. *In the lines of equal parts.* Having 3 numbers given, 4, 7, 16, to find out a 4th proportional. To do this, take the lateral extent of 16 in the line C L, and apply it parallel-wise, from 4 to 4, by a proper opening of the sector; then take the parallel distance from 7 to 7 in your compasses, and applying one foot in C, the other will fall on 28 in the line of lines C L, and is the number required; for 4 : 7 :: 16 : 28.

Ex. 2. *In the lines of chords.* Suppose it required to lay off an angle A C B, (fig. 4) equal to 35 degrees; then with any convenient opening of the sector, take the extent from 60 to 60, and with it (as radius) on the point C describe the arch A D indefinitely; then in the same opening of the sector take the parallel distance from 35 degrees to 35 degrees, and set it from A to B in the arch A D and draw A B, and it makes the angle at C required.

Ex. 3. *In the lines of sines.* The lines of sines, tangents, and secants, are used in conjunction with the lines of lines in the solution of all the cases of plain trigonometry; thus let there be given in the triangle A B C, (fig. 14) the side A B = 230; and the angle A B C = 36° 30′; to find the side A C. Here the angle at C is 53° 30′. Then take the lateral distance 230, from the line of lines, and make it a parallel from 53° 30′ to 53° 30′ in the line of sines; then the parallel distance between 36° 30′ in the same lines, will reach laterally from the centre to 170, 19 in the line of lines for the side A C required.

Ex. 4. *In the lines of tangents.* If instead of making the side B C radius (as before) you make A B radius; then A C which before was a sine, is now the tangent of the angle B; and therefore to find it, you use the lines of tangents, thus:

Take the lateral distance 230 from the line of lines, and make it a parallel distance on the tangent radius, viz. from 45° to 45°, then the parallel tangent from 36° 30′, to 36° 30′, will measure laterally on the line of lines 170, 19, as before, for the side A C.

Ex. 5. *In the lines of secants.* In the same triangle, in the base A B, and the angles at B and C given, as before, to find the side or hypothenuse B C. Here B C is the secant of the angle B.

Take the lateral distance 230 from the line of lines, and make it a parallel distance on the tangent radius or beginnings of the lines of secants; then the parallel secant of 60° 30′ will measure laterally on the line of lines 287, 12, for the length of B C as required.

Ex. 6. *In the lines of sines and tangents conjointly.* In the solution of spherical triangles, you use the line of sines and tangents only, as in the following example. In the spherical triangle A B C (fig. 15) right-angled at A, there are given the side A B = 36° 15′, and the adjacent angle B = 42° 34′, to find the side A C. The analogy is radius: sine of A B :: tangent of B : tangent of A C; therefore make the lateral sine of 36° 15′ a parallel at radius, or between 90 and 90; then the parallel tangent of 42° 34′ will give the lateral tangent of 28° 30′ for the side A C.

Ex. 7. *In the lines of polygons.* It has been observed that the chord of 60 degrees is equal to radius; and 60° is the sixth part of 360°; therefore such a chord is the side of a hexagon, inscribed in a circle: so that in the line of polygons, if you make the parallel distance between 6 and 6, the radius of a circle, as A C (fig. 16), then if you take the parallel distance between 5 and 5, and place it from A to B, the line A B will be the side of a pentagon A B D E F, inscribed in the circle; in the same manner may any other polygon, from 4 to 12 sides, be inscribed in a circle, or upon any given line A B.

Ex. 8. *Of Gunter's lines.* We have now shewn the use of all that are properly called sectoral lines, or that are to be used sectorwise; but there is another set of lines usually put upon the sector, that will in a more ready and simple manner give the answers to the questions in the above examples, and these are called artificial lines of numbers, sines, and tangents: because they are only the logarithms of the natural numbers, sines, and tangents, laid upon lines of scales, which method was first invented by Mr. Edmund Gunter, and is the reason why they have ever since been called Gunter's lines, or the Gunter.

Logarithms are only the ratios of numbers, and the ratios of all proportional numbers are equal. Now all questions in multiplication, division, the rule of three, and the analogies of plain and spherical trigonometry, are all stated in proportional numbers or terms; therefore, if in the compasses you take the extent (or ratio) between the first and second terms, that will always be equal to the extent (or ratio) between the third and fourth terms; and consequently, if with the extent between the first and second terms, you place one foot of the compasses on the third term, then turning the compasses about, the other foot will fall on the fourth term sought.

Thus in example I, of the three given numbers 4, 7, and 16, if you take the extent from 4 to 7 in the compasses, and place one foot in 16, the other will fall on 28 the answer, in the line of numbers marked *n*.

Again, the artificial lines of numbers and sines, are used together in plain trigonometry, as in example 3, where the two angles B and C, and the side AB are given; for here if you take the extent of the two angles 53° 30′ and 36° 30′ in the line of sines marked *s*, then placing one foot upon 230 in the line of numbers *n*, the other will reach to 170, 19 the answer.

Also the lines of numbers and tangents are used conjointly, as in the example 4, for take in the line of tangents *t*, the extent from 45° (radius) to 36° 30′; that will reach from 230 to 170, 19 the answer as before.

Lastly, the artificial lines of sines and tangents are used together in the analogies of spherical triangles.

Thus example 6 is solved by taking in the line of sines *s*, the extent from 90° (radius) to 36° 15′, then that in the line of tangents *t*, will reach from 42° 34′ to 28° 30′, the answer required.

We shall only further observe that each pair of sectoral lines contain the same angle, viz. 6 degrees in the common 6-inch sector; therefore to open these lines to any given angle, as 35° for instance, you have only to take 35° laterally from the line of chords, and apply it parallelwise from 60° to 60° in the same lines, and they will all be opened to the given angle of 35°.

If to the angle 35° you add the angle 6°, which they contain, the sum is 41°: then take 41° laterally from the line of chords, and apply it parallelwise, from 60 to 60, then will the sides or edges of the sector contain the same angle of 35 degrees.

Of proportional compasses. Though this sort of compasses does not pertain to a common case of instruments, yet a short account of their nature and use may not be unacceptable to those who are not acquainted with them. They consist of two parts or sides of brass, which lie upon each other, so nicely as to appear but one when they are shut. These sides easily open, and move about a centre, which is itself moveable in a hollow canal cut through the greatest part of their length. To this centre on each side is affixed a sliding piece of a small length, with a fine line drawn on it serving as an index, to be set against other lines or divisions placed upon the compasses on both sides. These lines are: 1. A line of lines. 2. A line of superficies, areas, or plans. 3. A line of solids. 4. A line of circles, or rather of polygons to be inscribed in circles.

These lines are all unequally divided, the three first from 1 to 10, the last from 6 to 20; their uses are as follow:

By the line of lines you divide a given line into any number of equal parts; for by placing the index against 1, and screwing it fast, if you open the compasses, then the distance between the points at each end will be equal. If you place the index against 2, and open the compasses, the distance between the points of the longer legs will be twice the distance between the shorter ones; and thus a line is bisected, or divided into two equal parts. If the index be placed against 3, and the compasses opened, the distances between the points will be as 3 to 1, and so a line is divided into three equal parts; and so you proceed for any other number of parts under 10.

The numbers of the line of plans answer to the squares of those in the line of lines; for because superficies or plans are to each other, as the squares of their like sides, therefore if the index be placed against 2 in the line of plans; then the distance between the small points will be the side of a plan whose area is 1; but the distance of the larger points will be the like side of a plan whose area is 2, or twice as big. If the index be placed at 3, and the compasses opened, the distances between the points at each end will be the like sides of plans, whose areas are 1 to 3, and so of others.

The numbers of the line of solids answer to the cubes of those in the line of lines; because all solids are to each other as the cubes of their like sides or diameters; therefore, if the index be placed to No. 2, 3, 4, &c. in the line of solids, the distances between the lesser and larger points will be the like sides of solids, which are to each other as 1 to 2, 1 to 3, 1 to 4, &c. For example, if the index be placed at 10, and the compasses be opened, so that the small points may take the diameter of a bullet weighing 1 ounce, then the distance between the larger points will be the diameter of a bullet or globe of 10 ounces, or which is 10 times as big.

Lastly the numbers in the line of circles are the sides of polygons to be inscribed in a given circle, or by which a circle may be divided into those equal parts from 6 to 20. Thus if the index be placed at 6, the points of the compasses at either end, when opened to the radius of a given circle, will contain the side of a hexagon, or divide the circle into 6 equal parts. If the index be placed against 7, and the compasses opened, so that the larger points may take in the radius of the circle; then the shorter points will divide the circle into 7 equal parts for inscribing a heptagon. Again, placing the index to 8, and opening the compasses, the larger points will contain the radius, and the lesser points divide the circle into 8 equal parts, for inscribing an octagon or square. And thus you proceed for others.

INSTRUMENTS, *surgical.* A case of pocket instruments for surgeons, which they ought always to carry about with them, contains lancets of different sizes; scissars fit for several uses; forceps, plain and furnished with teeth; incision-knives, straight and crooked; a spatula, probes, needles, &c. See SURGERY.

INSURANCE, LAWS OF. Insurance is regarded by the law as a contract between two or more parties; that on one paying a certain premium he shall be indemnified or insured against certain risks set forth in the policy. This is extremely convenient in commerce, but was made use of as a kind of gambling till the statute 14 Geo. III. c. 48, that no insurance shall be made on lives, or on any other event, wherein the party insured hath no interest; that in all policies the name of such interested party shall be inserted, and nothing more shall be recovered thereon than the amount of the interest of the insured. This, however, does not extend to marine insurances. But as it was a common practice of insuring large sums without having property on board, and which were called wager policies or insurances, interest or no interest, and of insuring the same goods several times over, it was enacted, that all insurances, interest or no interest, or without further proof of the interest than the policy, or by way of gaming, or without benefit of salvage to the insurer, should be void, except on privateers, or on ships or goods from the Spanish or Portuguese dominions; and that no re-assurance shall be legal, unless the former insurer be insolvent or dead; and that in the East India trade the lender of money on bottomry, or at respondentia, shall alone have a right to be insured for the money lent; and the borrower shall recover no more upon any insurance than the surplus of his bottomry or respondentia bond. No insurance can be made on any illegal voyage.

It is generally stipulated in policies that the insurer shall not be answerable for any partial loss on certain articles, but on others less difficult to be preserved at sea, but liable to partial injuries, shall be liable for any partial loss above five per cent.; and as to all other goods, and the ship and freight, he shall only be liable for such losses above three per cent. But he is liable on all losses, however small, called general average or losses occasioned by the ship stranding; but this loss must be an immediate, not a remote, consequence of the stranding.

The commencement of the risk on the ship varies in most cases, and usually continues till the ship has been 24 hours at safe anchor. Upon goods it commences when they are on board, and continues till they are removed or landed. The ship insured must be sound, and in every respect fit to bear the sea, and perform the voyage; and if she deviates from the usual course, and stops at places not usually stopped at, without a proper cause, the contract is void.

Insurance upon life is a contract by which the insurer, for a certain sum proportioned to the age, health, and profession of the person whose life is to be insured, engages that the person shall not die within a certain period, or if he do, the underwriter will pay a sum of money to the person to whom the policy is granted.

Insurance against fire. The insurer undertakes, in consideration of a premium, to indemnify the insured against all losses by fire which he may sustain in his house or goods during the time mentioned in the policy.

INTAGLIOS, precious stones on which are engraven the heads of great men, inscriptions, and the like; such as we frequently see set in rings, seals, &c.

INTEGER, in arithmetic, a whole number, in contradistinction to a fraction.

INTERCALARY, in chronology. See BISSEXTILE, &c.

INTERCOMMONING, in law, is when the commons of two manors lie together, and the inhabitants of both have, time out of mind, caused their cattle to feed promiscuously on them.

INTERCOSTAL. See ANATOMY.

INTERDICT, an ecclesiastical censure,

by which the church of Rome forbids the performance of divine service in a kingdom, province, town, &c. This censure has been frequently executed in France, Italy, and Germany; and in the year 1170 pope Alexander III. put all England under an interdict, forbidding the clergy to perform any part of divine service, except baptising of infants taking confessions, and giving absolution to dying penitents.

INTEREST, a sum of money, paid or allowed for the loan or use of some other sum, lent for a certain time, according to some fixed rate or proportion. The sum lent, and on which the interest is reckoned, is called the principal; and in any case where there is hazard of the loss or diminution of the principal, a proportionately greater interest is usually paid. The current rate of interest is generally considered as the barometer of public credit; and its lowness is a sign almost infallible of the flourishing condition of a state; it proves the increase of industry, and the free circulation of wealth, little inferior to a demonstration. In order to prevent individuals from taking unjust advantages of the necessities of others, it has been found necessary in most countries to establish by law a fixed rate of interest for the use of money: this however must, in a great measure, depend on the current rate of interest in the country; for if it is attempted to reduce by law the common rate of interest below the lowest ordinary market rate, the restriction will be sure to be evaded. This was the case in France in 1766, when, although the legal rate of interest was reduced from five to four per cent., money continued to be lent at five per cent.

The first act of parliament for regulating the interest for money lent in England was 37 Hen. VIII. c. 9, by which interest was fixed at 10 per cent.; before that time interest had usually been taken at higher rates. In 1552 an act was passed against usury, or taking any interest whatever for money lent: the impolicy and oppression of this measure soon became evident; and in 1571 the statute of Henry VIII. which fixed interest at 10 per cent., was revived. As the increase of commerce brought wealth into the country, the rate of interest lowered; and in 1625 it was, by 21 James I. c. 17, reduced to eight per cent. The first positive law made in Scotland for fixing the rate of interest was in 1587, when an act was passed, by which the rate of interest was not for the future to exceed 10 per cent. In France, in 1601, Henry IV. issued an edict for reducing the public or national interest of money in that kingdom to six and a quarter per cent. In 1651 the interest of money in several parts beyond sea being lower than the legal interest in England, the Rump-parliament reduced the legal rate from eight to six per cent.; and upon the Restoration it was confirmed by 12 Cha. II. c. 13. The last act of parliament for regulating the interest of money was 12 Ann. st. 2. c. 16, by which it was fixed at five per cent. per annum, the present legal rate. But although this is the utmost interest which can be taken for money lent in Great Britain, yet if a contract which carries interest was made in a foreign country, our courts will direct the payment of interest according to the laws of the country in which the contract was made: thus American, Turkish, and Indian interest have been allowed, to the amount of even 12 per cent.

The various rates which have been paid in Great Britain at different periods, as the current interest for money, are as follows:

	Per cent. per ann.		
In 1255 - - -	£. 50	0	0
1263, 2*d.* a-week for 1*l.* or	43	6	8
1270 to 1307 - -	45	0	0
1422 to 1470 - -	15	0	0
1545 restricted to -	10	0	0
1553 to 1558 -	12	0	0
1571 restricted to -	10	0	0
1524 to 1604, about -	9	16	0
1625 reduced to -	8	0	0
1645 to 1660 - -	6	0	0
1660 reduced to -	6	0	0
1660 to 1690 - -	7	6	6
1690 to 1697 - -	7	10	0
1697 to 1706 - -	6	0	0
1714 reduced to -	5	0	0

In the United States of America, the lawful interest of money is 6 per cent. in most of the States; in a few it is 7 per cent.; in one it is 5 per cent. In Greece, the mean rate of interest is 20 per cent., and in the other parts of Turkey nearly the same; in Persia 25 per cent.; and in the Mogul Empire 30 per cent. In these countries there is no fixed rate of interest, and the usual high rate arises chiefly from the insecurity of lending. In Sydney and the other English settlements in New South Wales, the rate of interest is fixed by an ordinance, dated 14th June, 1804, at 8 per cent. per annum.

Interest is distinguished into *Simple Interest* and *Compound Interest.*

INTEREST, *Simple*, is that which is reckoned on the principal only, at a certain rate for a year, and at a proportionately greater or less sum for a greater or less time; thus, if 5*l.* is the rate of interest of 100*l.* for a year, 10*l.* is the interest for two years, 15*l.* for three years, &c. In most computations of interest the work is much shortened if the interest of 1*l.* for a given term is known, as the interest of any other sum for the same term will then be found by only multiplying by the given sum. The interest of 1*l.* for a year must be in the same proportion as the interest of 100*l.* to its principal; therefore, at 5 per cent., as $100 : 5 :: 1 : \frac{5}{100} = ,05$; and thus:—

The interest of One Pound for One Year,

£.		£.
at 3 per cent. is	- -	,03
$3\frac{1}{2}$	- - - -	,035
4	- - - -	,04
$4\frac{1}{2}$	- - - -	,045
5	- - - -	,05
$5\frac{1}{2}$	- - - -	,055
6	- - - -	,06

The interest of One Pound for any number of years.

Years.	3 per Cent.	$3\frac{1}{2}$ per Cent.	4 per Cent.	$4\frac{1}{2}$ per Cent.	5 per Cent.
10	,3	,35	,4	,45	,5
20	,6	,7	,8	,9	1,0
30	,9	1,05	1,2	1,35	1,5
40	1,2	1,4	1,4	1,8	2,0
50	1,5	1,75	2,0	2,25	2,5
60	1,8	2,1	2,4	2,7	3,0
70	2,1	2,45	2,8	3,15	3,5
80	2,4	2.8	3,2	3,6	4,0
90	2,7	3,15	3,6	4,05	4,5
100	3,0	3,5	4,0	4,5	5,0

Although the law forbids any person lending money to take more than 5*l.* for the interest of 100*l.* for a year; yet by allowing the proportionate part of 5*l.* to be taken for part of a year, it permits any one who lends money for a less term than a year, to receive more than he ought if he were to make only 5 per cent. per annum of his money; for, if he lends 100*l.* for six months, he receives 102*l.* 10*s.*, and this being lent again for the remaining six months, amounts to 105*l.* 1*s.* 3*d.*; if the time is less than six months the difference must be still greater. The letter of the law is however the rule in practice, and therefore the 365th part of the yearly interest is always considered as the proper interest for a day, and its multiples as the interest for any number of days.

The Interest of One Pound for One Day,

As tables of Simple Interest are chiefly referred to, in order to find the interest or discount on bills of exchange, and as by far the greater number of bills which are discounted have less than 100 days to run, the following table will answer most useful purposes; but those who have constant occasion to make such computations, will derive much assistance from the extensive tables which have been computed by Smart, Thomson, King, Reid, and others. See also DISCOUNT.

TABLE

Shewing the Simple Interest of One Pound, for any number of days. not exceeding 100, at 5 per Cent.

days	Amount.	days	Amount.	days	Amount.

34	,0046575	68	,0093150		

The interest of any sum for any number of days contained in the table, is found by only multiplying the figures corresponding with the number of days by the sum: thus, if the interest of 150*l.* for 61 days is required, the interest of one pound for 61 days is, by the table, ,0083561, which multiplied by 150, gives 1*l.* 5*s.* $0\frac{3}{4}$*d.* If the given sum contains shillings and pence, they must be reduced to the decimal of a pound.

The interest for any greater number of days than are contained in the table, is easily found by means of it; thus, if it is required to find the interest of 100*l.* for 165 days, the interest for 100 days by the table is 1,36986, and for 65 days ,89041, which two sums added together, make 2,26027, or 2*l.* 5*s.* 2*d.* But, although it is most convenient in common practice to make use of tables for finding the interest for days, the interest of any sum for any number of days may be correctly and expeditiously obtained without the use of any table, by the following rule:

"Multiply the given sum by the number of days, and divide by 7300."

Example 1. What is the interest of 356*l.* for 112 days?

356 multiplied by 112, and divided by 7300, gives 5,4619, or 5*l.* 9*s.* 2¼*d.*

Example 2. What is the interest of 137*l.* 18*s.* for 97 days?

137,9 multiplied by 97, and divided by 7300, gives 1,8323, or 1*l.* 16*s.* 7¾*d.*

The amount of a given sum in any time may be found by multiplying the Principal, Time, and Rate together; and adding the product to the principal.

Example 1. What sum will 37*l.* 10*s.* amount to in 3 years and 146 days, at 4 per cent. per annum?

37,5 multiplied by 3,4, and the product multiplied by ,04, gives 5,1; which added to 37,5, makes 42,6, or 42*l.* 12*s.*

Example 2. What sum will One Penny amount to in 1806 years, at 5 per cent. per annum?

,004166 multiplied by 1806, and the product multiplied by ,05, gives ,37625, which, added to the principal, makes ,380416, or 7*s.* 7¼*d.*

This example sets the difference between simple and compound interest in a most striking point of view; it appears that one penny put out to interest at the birth of Christ, would (at 5 per cent. simple interest) have amounted at the present time to 7*s.* 7¼*d.*, but at compound interest, it would have increased in the same period to a greater sum than would be contained in six hundred millions of globes, each equal to the earth in magnitude, and all solid gold.

Interest, *compound*, is that which is reckoned on the principal and its interest put together, as the interest becomes due, so as to form a new capital from each period at which the interest is payable: it is sometimes called interest upon interest. It is not lawful to lend money at compound interest; but in the granting or purchasing of annuities, leases, or reversions, it is usual to allow the purchaser compound interest for his money; and the difference from simple interest is so great, in all cases in which the period of time is considerable, that almost all computations relating to annual payments of money for a number of years, are made at compound interest, unless it is otherwise agreed.

Let $r =$ the amount of 1*l.* in one year, viz. principal and interest,
$n =$ the number of years, in which
$p =$ the principal, increases to
$a =$ the amount:

then $1 : r :: r : r^2$ the amount of 1*l.* in 2 years
$1 : r :: r^2 : r^3$ the amount of 1*l.* in 3 years
$1 : r :: r^3 : r^4$ the amount of 1*l.* in 4 years, &c.;

therefore r^n, or r raised to the power whose exponent is the number of years, will be the amount of 1*l.* in those years; and as

$1l. : r^n :: p : a$, the amount of a given principal in the same time. Thus,

If Principal, Time, and Rate, are given, to find the Amount?

Theo. 1. $p \times r^n = a$.

If Amount, Time, and Rate, are given, to find the Principal?

Theo. 2. $\frac{a}{r^n} = p$.

If Principal, Amount, and Time, are given, to find the Rate?

Theo. 3. $\sqrt[n]{\frac{a}{p}} = r$.

If Principal, Amount, and Rate, are given, to find the Time?

Theo. 4. $\frac{a}{p} = r^n$, therefore $\frac{a}{p}$ being divided by r till nothing remains, the number of divisions will $= n$.

But for greater convenience in practice, these theorems may be expressed in logarithms, as follows:

1. $\log. p + \overline{n \times \log. r} = \log. a$.
2. $\log. a - \overline{n \times \log. r} = \log. p$.
3. $\frac{\log. a - \log. p}{n} = \log. r$.
4. $\frac{\log. a - \log. p}{\log. r} = n$.

On these principles all tables of Compound Interest are formed, of which the following are the most useful.

TABLE I.

Shewing the Sum to which 1*l.* Principal will increase at 5 per Cent. Compound Interest, in any number of years not exceeding a hundred.

Yrs.	Amount.	Yrs.	Amount.	Yrs.	Amount.
1	1.05	35	5.516015	69	28.977548
2	1.1025	36	5.791816	70	30.426425
3	1.157625	37	6.081406	71	31.947746
4	1.215506	38	6.385477	72	33.545134
5	1.276281	39	6.704751	73	35.222390
6	1.340095	40	7.039988	74	36.983510
7	1.407100	41	7.391988	75	38.832685
8	1.477455	42	7.761587	76	40.774320
9	1.551328	43	8.149666	77	42.813036
10	1.628894	44	8.557150	78	44.953688
11	1.710339	45	8.985007	79	47.201372
12	1.795856	46	9.434258	80	49.561441

15	2.078928	49	10.921333	83	57.373563
16	2.182874	50	11.467399	84	60.242241
17	2.292018	51	12.040769	85	63.254353
18	2.406619	52	12.642808	86	66.417071
19	2.526950	53	13.274948	87	69.737924
20	2.623297	54	13.938696	88	73.224820
21	2.785962	55	14.635630	89	76.886061
22	2.925260	56	15.367412	90	80.730365
23	3.071523	57	16.135783	91	84.766883
24	3.225099	58	16.942572	92	89.005227
25	3.386354	59	17.789700	93	93.455488
26	3.555672	60	18.679185	94	98.128263
27	3.733456	61	19.613145	95	103.034676
28	3.920129	62	20.593802	96	108.186410
29	4.116135	63	21.623492	97	113.595730
30	4.321942	64	22.704667	98	119.275517
31	4.538039	65	23.839900	99	125.239293
32	4.764941	66	25.031895	100	131.501257
33	5.003188	67	26.283490		
34	5.253347	68	27.597664		

In order to find what any sum will amount to in a given number of years, it is only necessary to multiply the number in the Table opposite to the term of years by the sum, and the product will be the answer.

Example. To what sum will 50*l.* increase in 69 years, at 5 per cent. compound interest?

The number in the table corresponding with 69 years is 28.977548, which multiplied by 50, gives 1448.8774, or 1448*l.* 17*s.* 6*d.*

The number of years in which a given sum will increase to another given sum in consequence of being improved at interest, is found by dividing the latter sum by the former, and the sum in the table which is nearest to the quotient will shew the term required.

Example. In what time will 100*l.* increase to 500*l.*, if improved at 5 per cent.?

Divide 500 by 100, and the number in the table nearest to 5 the quotient, is 5.003188, which shews that 33 years is the answer.

TABLE II.

Shewing the present Value of 1*l.* to be received at the end of any number of years, not exceeding 100; discounting at 5 per Cent. Compound Interest.

Yrs.	Value.	Yrs.	Value.	Yrs.	Value.
1	.952381	35	.181290	69	.034509
2	.907029	36	.172657	70	.032866
3	.863838	37	.164436	71	.031301

30	.231377	64	.044044	98	.008384
31	.220359	65	.041946	99	.007985
32	.209866	66	.039949	100	.007604
33	.199873	67	.038047		
34	.190355	68	.036235		

In order to find the present worth of any sum which is to be received at the end of a certain number of years, multiply the number in the table opposite to the term of years, by the sum, and the product will be the answer.

Example. What is the present value of 500*l.* to be received at the expiration of 14 years?

The number in the table corresponding with 14 years, is .505068, which multiplied by 500, gives 252,534, or 252*l.* 10*s.* 8*d.*

For the present value or amount of annual payments, as Annuities, Pensions, Leases, &c. at Compound Interest, see Annuities.

Interest, in law, is generally taken for a chattel real, or a lease for years, &c. but more for a future term.

An estate in lands, &c. is better than a bare interest therein; yet, according to the legal sense of the word, an interest extends to estates and titles which a person has in or out of lands, &c.; for by grant of a person's whole interest in land, a reversion, as well as possession, in fee-simple, passes.

INTERJECTION, in grammar, an indeclinable part of speech, signifying some passion or emotion of the mind.

INTERLOCUTORY ORDER, in law, an order that does not decide the cause, but only some matter incident to it, which happens between the beginning and end of a cause; as when, in chancery or exchequer, the plaintiff obtains an order for an injunction until the hearing of the cause; which order, not being final, is called interlocutory.

INTERMITTENT, or INTERMITTING FEVERS. See MEDICINE.

INTERNAL, in general, signifies whatever is within a thing.

Euclid proves that the sum of the three internal angles of every triangle is equal to two right angles; whence he deduces several useful corollaries. He likewise adduces, from the same proposition, this theorem, viz. that the sum of the angles of every rectilinear figure, is equal to twice as many right angles, as the figure hath sides, excepting or subtracting four.

INTERROGATORIES, are questions exhibited in writing to be asked witnesses or contemnors to be examined. Those interrogatories are in the nature of a charge or accusation; and if any of them is improper, the defendant may refuse to answer it, and move the court to have it struck out. Str. 444.

INTERSECTION, in the mathematics, signifies the cutting of one line or plane by another: thus we say, that the mutual intersection of two planes is a right line.

INTERVAL, in music, the difference in point of gravity or acuteness between any two sounds. Taking the word in its more general sense, we must allow that the possible intervals of sound are infinite, but we only speak of those intervals which exist between the different tones of any established system. The antients divided the intervals into simple, or uncomposite, which they call diastems, and composite intervals, which they call systems. The least of all the intervals in the Greek music was, according to Bacchius, the enharmonic diesis, or fourth of a tone; but our scale does not notice so small a division, since all our tones concur in consonances, to which order only one of the three antient genera, viz. the diatonic, was accommodated. Modern musicians consider the semitone as a simple interval, and only call those composite which consist of two or more semitones:, thus from B to C is a semitone, or simple interval, but from C to D is two half-tones, or a compound interval.

INTESTATES. There are two kinds of intestates; one that makes no will at all; and another that makes a will, and nominates executors, but they refuse; in which case he dies an intestate, and the ordinary commits administration. 2 Par. Inst. 397.

The ordinary by special acts of parliament is required to grant administration of the effects of the deceased to the widow or next of kin, who shall first pay the debts of the deceased, and then distribute the surplus among the kindred, in the manner and according to the proportions directed by 22 and 23 Car. II. c. 10.

INTESTINA, in natural history, an order of vermes. The individuals of this order are of a formation the most simple, and live some of them within other animals, some in waters, and a few in the earth. The gordius perforates clay to give a passage to springs and water; the lumbricus pierces the earth, that it may be exposed to the action of the air and moisture: in like manner the teredo penetrates wood; and the phloas and mytillus rocks, to effect their dissolution.

INTESTINES. See ANATOMY, and PHYSIOLOGY.

INTRUSION, in law, is when the ancestor dies seised of any estate of inheritance, expectant upon an estate for life; and then the tenant for life dies, between whose death, and the entry of the heir, a stranger intrudes.

INVECTED, in heraldry, denotes a thing fluted or furrowed. See HERALDRY.

INVENTION. See PAINTING.

INVESTITURE, in law, is the giving possession of lands by actual seisin. The ancient feudal investiture was, where the vassal on descent of land was admitted into the lord's court, and there received his seisin, in the nature of a renewal of his ancestor's grant, in the presence of the rest of the tenants: but in aftertimes, entering on any part of the lands, or other notorious possession, was admitted to be equivalent to the formal grant of seisin and investiture. 2 Black. 209.

The manner of grant was by words of pure donation, "have given and granted:" which are still the operative words in our modern infeodations or deeds of feoffment. This was perfected by the ceremony of corporal investiture, or open and notorious delivery of possession in the presence of the other vassals.

But a corporal investiture being sometimes inconvenient, a symbolical delivery of possession was in many cases anciently allowed of; by transferring something near at hand, in the presence of credible witnesses, which by agreement should serve to represent the very thing designed to be conveyed; and an occupancy of this sign or symbol was permitted as equivalent to the occupancy of the land itself. And to this day, the conveyance of many of our copyhold estates is made from the seller to the lord, or his steward, by delivering a rod or verge, and then from the lord to the purchaser, by a re-delivery of the same, in the presence of a jury of tenants. 2 Black. 313.

INULA, fleabane, a genus of the syngenesia polygamia-superflua class of plants, with radiated flowers: the receptacle is naked; the down is simple; and the antheræ terminate in setæ at their bases. There are thirty-four species, of no note.

INVOICE, an account in writing of the particulars of merchandise, with their value, custom, charges, &c. transmitted by one merchant to another in a distant country.

One copy of every invoice is to be inserted verbatim in the invoice-book, for the merchant's private use; and another copy must, immediately upon shipping off the goods, be dispatched by post, or otherwise, to the correspondent. This copy is commonly drawn out upon a sheet of large post-paper, to the end of which is subjoined a letter of advice.

INVOLUCRUM. See BOTANY.

INVOLUTION. See ALGEBRA.

JOINT ACTIONS: in personal actions, several wrongs may be joined in one writ; but actions founded upon a tort and a contract cannot be joined, for they require different pleas and different process. 1 Vent. 336.

JOINT AND SEVERAL: an interest cannot be granted jointly and severally; as if a man grants the next advowson, or makes a lease for years, to two jointly and severally; these words (severally) are void, and they are joint tenants. 5 Rep. 19.

JOINT LIVES: lease for years to husband and wife, if they or any issue of their bodies should so long live, has been adjudged so long as either the husband, wife, or any of their issue, should live; and not only so long as the husband and wife, &c. should jointly live. Moor, 539.

JOINT TENANTS, are those that come to, and hold lands or tenements by one title pro indiviso, or without partition.

These are distinguished from sole or several tenants, from parceners, and from tenants in common: and they must jointly implead, and jointly be impleaded by others, which properly is common between them and coparceners; but joint tenants have a sole quality of survivorship, which coparceners have not; for if there are two or three joint tenants, and one has issue and dies, then he or those joint tenants that survive, shall have the whole by survivorship. Cowel.

The creation of an estate in joint tenantcy depends on the wording of the deed or devise, by which the tenant claims title; for this estate can only arise by purchase or grant, that is, by the act of the parties; and never by the mere act of law. Now if any estate is given to a plurality of persons, without adding any restrictive, exclusive, or explanatory words, as if an estate is granted to A and B and their heirs, this makes them immediately joint tenants in fee of the lands; for the law interprets the grant, so as to make all parts of it take effect, which can only be done by creating an equal estate in them both. As therefore the grantor has thus united their names, the law gives them a thorough union in all other respects. 2 Black. 180.

If there are two joint tenants, and one releases the other, this passes a fee without the word heirs, because it refers to the whole fee, which they jointly took, and are possessed of by force of the first conveyance; but the tenants in common, cannot release to each other, for a release supposes the party to have the thing in demand, but tenants in common have several distinct freeholds, which they cannot transfer otherwise than as persons who are sole seized. Co. Lit. 9.

Although joint tenants are seized per mie et per tout, yet to divers purposes each of them has but a right to a moiety; as to enfeoff, give, or demise, or to forfeit or lose by default in a præcipe; and therefore where there are two or more joint tenants, and they all join in a feoffment, or each of them in judgment gives but his part. Co. Lit. 186.

The right of survivorship shall take place immediately upon the death of the joint tenant, whether it is a natural or civil death; as if there are two joint tenants, and one of them enters into religion, the survivor shall have the whole. Co. Lit. 181.

At common law, joint tenants in common were not compellable to make partition, except by the custom of some cities and boroughs. Co. Lit. 187.

But now joint tenants may make partition; the one party may compel the other to make partition, which must be by deed: that is to to say, all the parties must by deed actually convey and assure to each other the several estates, which they are to take and enjoy severally and separately. 2 Black. 324.

Joint tenants being seized per mie et per tout, and deriving by one and the same title, must jointly implead, and be jointly impleaded with others. Co. Lit. 180.

If one joint tenant refuses to join in action, he may be summoned and severed; but herein it is to be observed, that if the person severed dies, the writ abates, because the survivor then goes for the whole, which he cannot do on that writ, where on the summons and severance he went only for a moiety before; for the writ cannot have a double effect, to wit, for a moiety in case of summons and severance, and for the whole in case of survivorship. Co. Lit. 188.

But in personal and mixed actions where there is summons and severance, and yet after such summons and severance the plaintiff goes on for the whole, there if one of them dies, yet the writ shall not abate, because they go on for the whole after summons and severance; and if they were to have a new writ, it would only give the court authority to go on for the whole. Co. Lit. 197.

JOINTURE. A jointure strictly speaking, signifies a joint estate, limited to both husband and wife; but in common acceptation, it extends also to a sole estate, limited to the wife only, and may be thus defined, viz. a competent livelihood of freehold for the wife of lands and tenements, to take effect, in profit or possession, presently after the death of the husband; for the life of the wife at least. 2 Black. 137.

By the statute of the 27th H. VIII. c. 10. if a jointure is made to the wife, it is a bar of her dower, so that she shall not have both jointure and dower. And to the making of a perfect jointure within that statute six things are observed: 1. Her jointure is to take effect presently after her husband's decease. 2. It must be for the term of her own life, or greater estate. 3. It should be made to herself. 4. It must be made in satisfaction of her whole dower, and not of part of her dower. 5. It must either be expressed or averred to be in satisfaction of her dower. 6. It should be made during the coverture. 1 Inst. 32.

The estate must take effect presently after her husband's decease; therefore if an estate is made to the husband for life, remainder to another person for life, remainder to the wife for her jointure, this is no good jointure, for it is not within the words or intent of the statute; for the statute designed nothing as a satisfaction for dower, but that which came in the same place, and is of the same use to the wife; and though the other person dies during the life of the husband, yet this is not good; for every interest not equivalent to dower not being within the statute, is a void limitation to deprive the wife of her dower. 4 Co. 3.

The estate must be for term of the wife's life, or a greater estate; therefore if an estate is made for the life or lives of many others, this is no good jointure; for if she survives such lives, as she may, then it would be no competent provision during her life, as every jointure within the statute ought to be. Co. Lit. 36.

The estate should be made to herself; but as the intention of the statute was to secure the wife a competent provision, and also to exclude her from claiming dower, and likewise her settlement, it seems that a provision or settlement on the wife, though by way of trust, if in other respects it answers the intention of the statute, will be inforced in a court of equity.

The estate must be in satisfaction of the whole dower; the reason hereof is, that if it is made in satisfaction of part only, it is uncertain for what part it is in satisfaction of her dower, and therefore void in the whole. Co. Lit. 36.

The estate must be expressed or averred to be in satisfaction of her dower. Lord Coke says, that it must be expressed or averred to be in satisfaction of her dower; but quære, for this does not seem requisite either within the words or intention of the statute. Co. Lit. 36.

It should be made during the coverture; this the very words of the act of parliament require: and therefore if a jointure is made to a woman during her coverture in satisfaction of dower, she may wave it after her husband's death; but if she enters and agrees thereto, she is concluded; for though a woman is not bound by any act when she is not at her own disposal, yet if she agrees to it when she is at liberty, it is her own act, and she cannot avoid it. Co. Lit. 36. 4 Co. 3.

JOISTS, or Joysts. See Architecture.

JONCQUETIA, a genus of the decandria tetragynia class and order. The cal. is five-leaved; pet. five and spreading; filaments growing to a glandule; styles none; caps. sub-globular, one-celled, five-valved, five-seeded. There is one species, a large tree of Guiana.

IONIC ORDER. See Architecture.

JONK, or Jonque, in naval affairs, is a kind of small ship, very common in the East Indies: these vessels are about the bigness of our fly-boats, and differ in the form of their building, according to the different methods of naval architecture used by the nations to which they belong. Their sails are frequently made of mats, and their anchors are made of wood.

JOURNAL, at sea. See Navigation.

IPECACUANHA. See Materia Medica.

IPOMEA, *quamoclit*, or scarlet convolvulus, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 29th order, campanaceæ. The corolla is funnel-shaped; the stigma round-headed; the capsule trilocular. There are twenty-seven species; but not more than one (the coccinea) cultivated in our gardens. This has long, slender, twining stalks, rising upon support six or seven feet high, from the sides of which arise many slender footstalks, each supporting several large and beautiful funnel-shaped and scarlet flowers. There is a variety with orange-coloured flowers. Both of them are annual.

IRELAND. By statutes 39 and 40 Geo. III. c. 67. the kingdoms of Great Britain and Ireland shall, upon the first day of Jan. 1801, and for ever after, be united, by the name of the United Kingdom of Great Britain and Ireland; and the royal style and titles appertaining to the imperial crown of the said united kingdom and its dependancies, and also the ensigns armorial, flags and banners thereof, shall be such as his majesty, by his royal proclamation under the great seal of the united kingdom, shall be pleased to appoint.

Where a debt is contracted in England, and a bond is taken for it in Ireland, it shall carry Irish interest; for it must be considered as referable to the place where it is made: but if it was a simple-contract debt only, it ought to carry English interest, the variation of place in this case making no difference. 2 Atk. 382.

IRESINE, a genus of the pentandria order, in the diœcia class of plants; and in the natural method ranking under the 54th order, miscellaneæ. The male calyx is diphyllous, the corolla pentapetalous, and there are five nectaria. The female calyx is diphyllous, the corolla pentapetalous; there are two sessile stigmata, and a capsule with flocky seeds. There is one species, a herb of Jamaica.

IRIDIUM, a new metal lately discovered by Mr. Tennant in the ore of platina. It is of a white colour, and perfectly infusible. It does not combine with sulphur or arsenic. Lead unites with it, but may be separated by cupellation. Copper, silver, and gold, are found to combine with it.

IRIS, the flower-de-luce, or flag-flower, &c.; a genus of the monogynia order in the triandria class of plants; and in the natural method ranking under the sixth order, ensatæ. The corolla is divided into six parts; the petals alternately reflexed; the stigmata resembling petals.

There are fifty species, all herbaceous flowering perennials, both of the fibrous, tuberous, and bulbous-rooted kind, producing thick annual stalks from three or four inches to a yard high, terminated by large hexapetalous flowers, having three of the petals reflexed quite back, and three erect; most of which are very ornamental, appearing in May, June, and July. All the species are easily propagated by offsets from the roots, which should be planted in September, October, or November, though almost any time from September to March will do. They may also be raised from seed, which is the best method for procuring varieties. It is to be sown in autumn, soon after it ripens, in a bed or border of common earth, and raked in. The plants will rise in the spring, and are to be transplanted next autumn.

IRON, the most abundant, and the most useful of all metals, was neither known so early, nor wrought so easily as gold, silver, and copper.

Iron is of a bluish white colour; and when polished, has a great deal of brilliancy. It has a styptic taste, and emits a smell when rubbed. Its specific gravity varies from 7.6 to 7.8. It is attracted by the magnet or loadstone, and is itself the substance which constitutes the loadstone. But when iron is perfectly pure, it retains the magnetic virtue a very short time. It is malleable in every temperature, and its malleability increases in proportion as the temperature augments; but it cannot be hammered out nearly so thin as gold or silver, or even copper. Its ductility, however, is more perfect; for it may be drawn out into wire as fine at least as a human hair. Its tenacity is such, that an iron wire 0.078 of an inch in diameter is capable of supporting 549.25 lbs. avoirdupois without breaking. When heated to about 158° Wedgewood, it melts. This temperature being nearly the highest to which it can be raised, it has been impossible to ascertain the point at which this melted metal begins to boil and to evaporate. Neither has the form of its crystals been examined: but it is well known that the texture of iron is fibrous; that is, it appears when broken to be composed of a number of fibres or strings bundled together.

When exposed to the air, its surface is soon tarnished, and it is gradually changed into a brown or yellow powder, well known under the name of rust. This change takes place more rapidly if the atmosphere is moist. It is occasioned by the gradual combination of the iron with the oxygen of the atmosphere, for which it has a very strong affinity.

When iron filings are kept in water, provided the temperature is not under 70°, they are gradually converted into a black powder, while a quantity of hydrogen gas is emitted. This is occasioned by the slow decomposition of the water. The iron combines with its oxygen, while the hydrogen makes its escape under the form of gas.

If the steam of water is made to pass through a red-hot iron tube, it is decomposed instantly. The oxygen combines with the iron, and the hydrogen gas passes through the tube, and may be collected in proper vessels. This is one of the easiest methods of procuring pure hydrogen gas.

These facts are sufficient to show that iron has a strong affinity for oxygen, since it is capable of taking it from air and water. It is capable also of taking fire and burning with great rapidity. Twist a small iron wire into the form of a cork-screw, by rolling it round a cylinder; fix one end of it into a cork, and attach to the other a small bit of cotton thread dipt in melted tallow. Set fire to the cotton, and plunge it while burning into a jar filled with oxygen gas. The wire catches fire from the cotton, and burns with great brilliancy, emitting very vivid sparks in all directions. For this very splendid experiment we are indebted to Dr. Ingenhousz. During this combustion the iron combines with oxygen, and is converted into an oxide. Mr. Proust has proved that there are only two oxides of iron; the protoxide has usually a black colour, but the peroxide is red.

The protoxide of iron may be obtained by four different processes. 1. By keeping iron filings a sufficient time in water at the temperature of 70°. The oxide thus formed is a black powder, formerly much used in medicine under the name of martial ethiops, and seems to have been first examined by Lemeri; but a better process is that of De Roover. He exposes a paste formed of iron filings and water to the open air, in a stoneware vessel; the paste becomes hot, and the water disappears. It is then moistened again, and the process repeated till the whole is oxydized. The mass is then pounded, and the powder is heated in an iron vessel till it is perfectly dry, stirring it constantly. 2. By making steam pass through a red-hot iron tube, the iron is changed into a brilliant black brittle substance, which, when pounded, assumes the appearance of martial ethiops. This experiment was first made by Lavoisier. 3. By burning iron wire in oxygen gas. The wire as it burns is melted, and falls in drops to the bottom of the vessel, which ought to be covered with water, and to be of copper. These metallic drops are brittle, very hard, and blackish, but retain the metallic lustre. They were examined by Lavoisier, and found precisely the same with marthial ethiops. They owe their lustre to the fusion which they underwent. By dissolving iron in sulphuric acid, and pouring potass into the solution. 4. A green powder falls to the bottom, which assumes the appearance of martial ethiops when dried quickly in close vessels. This first oxide of iron, however formed, is always composed of 73 parts of iron and 27 of oxygen, as Lavoisier and Proust have demonstrated. It is attracted by the magnet, and is often itself magnetic. It is capable of crystallizing, and is often found native in that state.

The peroxide or red oxide of iron may be formed by keeping iron filings red-hot in an open vessel, and agitating them constantly till they are converted into a dark-red powder. This oxide was formerly called saffron of Mars. Common rust of iron is merely this oxide combined with carbonic acid gas. The red oxide may be obtained also by exposing for a long time a diluted solution of iron in sulphuric acid to the atmosphere, and then dropping into it an alkali, by which the oxide is precipitated. This oxide is also found native in great abundance. Proust proved it to be composed of 48 parts of oxygen and 52 of iron. Consequently the protoxide, when converted into red oxide, absorbs 0.40 of oxygen; or, which is the same thing, the red oxide is composed of 66.5 parts of black oxide and 33.5 parts of oxygen. One hundred parts of iron, when converted into a protoxide, absorb 37 parts of oxygen, and the oxide weighs 137; when converted into peroxide, it absorbs 52 additional parts of oxygen, and the oxide weighs 189.

The peroxide cannot be decomposed by heat; but when heated along with its own weight of iron filings, the whole, as Vauquelin first observed, is converted into black oxide. The reason of this conversion is evident: The 100 parts of peroxide are composed of 52 parts of iron, combined with two different doses of oxygen: 1. With 14 parts, which, with the iron, make 66 of protoxide: 2. With 34 parts, which, with the protoxide, make up the 100 parts of peroxide. Now, the first of these doses has a much greater affinity for the iron than the second has. Consequently the 34 parts of oxygen, which constitute the second dose, being retained by a weak affinity, are easily abstracted by the 100 parts of pure iron; and combining with the iron, the whole almost is converted into black oxide: for 100 parts of iron, to be converted into black oxide, require only 37 parts of oxygen.

The peroxide of iron is not magnetic. It is converted into black oxide by sulphureted hydrogen gas and many other substances; which deprive it of the second dose of oxygen, for which they have a stronger affinity, though they are incapable of decomposing the protoxide. Iron is capable of combining with all the simple combustible bodies.

A small mixture of it constitutes that particular kind of iron, known by the name of cold short iron, because it is brittle when cold, though it is malleable when hot.

Rinman has shewn that the brittleness and bad qualities of cold short iron may be removed by heating it strongly with limestone, and with this the experiments of Levavasseur correspond.

There are a great many varieties of iron, which artists distinguish by particular names; but all of them may be reduced under one or other of the three following classes: cast iron; wrought or soft iron; and steel.

Cast iron, or pig iron, is the name of the metal when first extracted from its ores. The ores from which iron is usually obtained are composed of oxide of iron and clay. The object of the manufacturer is to reduce the oxide to the metallic state, and to separate all the clay with which it is combined. These two objects are accomplished at once, by mixing the ore reduced to small pieces with a certain portion of limestone and of charcoal, and subjecting the whole to a very violent heat in furnaces constructed for the purpose. The charcoal absorbs the oxigen of the oxide, flies off in the state of carbonic acid gas, and leaves the iron in the metallic state; the lime combines with the clay, and both together run into fusion, and form a kind of fluid glass; the iron is also melted by the violence of the heat, and being heavier than the glass, falls down, and is collected at the bottom of the furnace. Thus the contents of the furnace are separated into two portions; the glass swims at the surface, and the iron rests at the bottom. A hole at the lower part of the furnace is now opened, and the iron allowed to flow out into moulds prepared for its reception.

The cast iron thus obtained is distinguished by the following properties: It is scarcely malleable at any temperature. It is generally so hard as to resist the file. It can neither be hardened nor softened by ignition and cooling. It is exceedingly brittle. It melts at 130° Wedgewood. It is more sonorous than steel. For the most part it is of a dark-grey or blackish colour; but sometimes it is whitish, and then it contains a quantity of phosphuret of iron, which considerably impairs its qualities. A great number of utensils are formed of iron in this state.

To convert it into wrought iron, it is put into a furnace, and kept melted, by means of the flame of the combustibles, which is made to play upon its surface. While melted, it is constantly stirred by a workman, that every part of it may be exposed to the air. In about an hour the hottest part of the mass begins to heave and swell, and to emit a lambent blue flame. This continues nearly an hour; and by that time the conversion is completed. The heaving is evidently produced by the emission of an elastic fluid. As the process advances, the iron gradually acquires more consistency; and at last, notwithstanding the continuance of the heat, it congeals all together. It is then taken while hot, and hammered violently, by means of a heavy hammer driven by machinery. This not only makes the particles of iron approach nearer each other, but drives away several impurities which would otherwise continue attached to the iron.

In this state it is the substance described under the name of iron. As it has never yet been decomposed, it is considered at present, when pure, as a simple body; but it has seldom or never been found without some small mixture of foreign substances. These substances are either some of the other metals, or oxygen, carbon, or phosphorus.

When small pieces of iron are stratified in a close crucible, with a sufficient quantity of charcoal-powder, and kept in a strong red heat for eight or ten hours, they are converted into steel, which is distinguished from iron by the following properties.

It is so hard as to be unmalleable while cold, or at least it acquires this property by being immersed while ignited into a cold liquid: for this immersion, though it has no effect upon iron, adds greatly to the hardness of steel.

It is brittle, resists the file, cuts glass, affords sparks with flint, and retains the magnetic virtue for any length of time. It loses this hardness by being ignited and cooled very slowly. It melts at above 130° Wedgewood. It is malleable when red-hot, but scarcely so when raised to a white heat. It may be hammered out into much thinner plates than iron. It is more sonorous; and its specific gravity, when hammered, is greater than that of iron.

By being repeatedly ignited in an open vessel, and hammered, it becomes wrought iron, which is a simple substance, and if perfectly pure would contain nothing but iron.

Steel is iron combined with a small portion of carbon, and has been for that reason called carbureted iron. The proportion of carbon has not been ascertained with much precision. From the analysis of Vauquelin, it amounts, at an average, to $\frac{1}{140}$ part. Mr. Clouet seems to affirm that it amounts to $\frac{1}{32}$ part; but he has not published the experiments which led him to a proportion, which so far exceeds what has been obtained by other chemists.

That steel is composed of iron combined with pure carbon, and not with charcoal, has been demonstrated by Morveau, who formed steel by combining together directly iron and diamond. At the suggestion of Clouet, he inclosed a diamond in a small crucible of pure iron, and exposed it completely covered up in a common crucible to a sufficient heat. The diamond disappeared, and the iron was converted into steel. The diamond weighed 907 parts, the iron 57800, and the steel obtained 56384; so that 2313 parts of the iron had been lost in the operation. From this experiment it follows, that steel contains about $\frac{1}{60}$ of its weight of carbon. This experiment was objected to by Mr. Mushet, but the objections were fully refuted by sir George M'Kenzie.

Rinman, long ago, pointed out a method by which steel may be distinguished from iron. When a little diluted nitric acid is dropt upon a plate of steel, allowed to remain a few minutes, and then washed off, it leaves behind it a black spot; whereas the spot formed by nitric acid on iron is whitish-green. We can easily see the reason of the black spot: it is owing to the carbon of the iron which is converted into charcoal by the acid. This experiment shows us, that carbon is much more readily oxidated when combined with iron than when crystallized in the diamond.

Cast iron, is iron combined with a still greater proportion of carbon than is necessary for forming steel. The quantity has not yet been ascertained with precision: Mr. Clouet makes it amount to $\frac{1}{8}$ of the iron. The blackness of the colour, and the fusibility of cast iron, are proportional to the quantity of carbon which it contains. Cast iron is almost always contaminated with foreign ingredients: these are chiefly oxide of iron, phosphuret of iron, and silica.

It is easy to see why iron is obtained from its ore in the state of cast iron. The quantity of charcoal, along with which the ore is fused, is so great, that the iron has an opportunity of saturating itself with it.

The conversion of cast iron into wrought iron is effected by burning away the charcoal, and depriving the iron wholly of oxygen: this is accomplished by heating it violently while exposed to the air. Mr. Clouet has found, that when cast iron is mixed with $\frac{1}{4}$ of its weight of black oxide of iron, and heated violently, it is equally converted into pure iron. The oxygen of the oxide, and the carbon of the cast iron, combine, and leave the iron in a state of purity.

The conversion of iron into steel is effected by combining it with carbon. This combination is performed in the large way by three different processes, and the products are distinguished by the names of natural steel, steel of cementation, and cast steel.

Natural steel is obtained from the ore by converting it first into cast iron, and then exposing the cast iron to a violent heat in a furnace while its surface is covered with a mass of melted scoriæ five or six inches deep. Part of the carbon combines with the oxygen which cast iron always contains, and flies off in the state of carbonic acid gas. The remainder combines with the pure iron, and constitutes it steel. This steel is inferior to the other species; its quality is not the same throughout; it is softer, and not so apt to break; and as the processes by which it is obtained are less expensive, it is sold at a lower price than the other species.

It is obvious that iron and carbon are capable of combining together in a variety of different proportions. When the carbon exceeds, the compound is carburet of iron, or plumbago. When the iron exceeds, the compound is steel or cast iron in various states, according to the proportion. All these compounds may be considered as subcarburets of iron. The hardness of iron increases with the proportion of charcoal with which it combines, till the carbon amounts to about $\frac{1}{60}$ of the whole mass. The hardness is then a maximum; the metal acquires the colour of silver, loses its granulated appearance, and assumes a crystallized form. If more carbon is added to the compound, the hardness diminishes in proportion to its quantity.

The affinities of iron, and its oxides, are arranged by Bergman as in the following table:

IRON.	OXIDE OF IRON.
Nickel,	Oxalic acid,
Cobalt,	Tartaric,
Manganese,	Camphoric,
Arsenic,	Sulphuric,
Copper,	Saclatic,
Gold,	Muriatic,
Silver,	Nitric,
Tin,	Phosphoric,
Antimony,	Arsenic,
Platinum,	Fluoric,
Bismuth,	Succinic,
Lead,	Citric,
Mercury.	Lactic,
	Acetic,
	Boracic,
	Prussic,
	Carbonic.

IRON-SICK, in the sea-language, is said of a ship or boat, when her bolts or nails are so eaten with rust, and so worn away, that they occasion hollows in the planks, whereby the vessel is rendered leaky.

IRRATIONAL, an appellation given to surd numbers and quantities. See ALGEBRA.

IRREGULAR, in grammar, such inflections of words as vary from the general rules; thus we say, irregular nouns, irregular verbs.

ISATIS, WOAD; a genus of the siliquosa order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, the siliquosa. The siliqua is lanceolated, unilocular, monospermous, bivalved, and deciduous; the valves navicular or canoe-shaped. There are four species; but the only one worthy of notice is the tinctoria, or common woad, which is cultivated in several parts of Britain for the purposes of dyeing, being used as a foundation for many of the dark colours. See DYEING.

ISCHÆMUM, a genus of the monœcia order, in the polygamia class of plants; and in the natural method ranking under the 4th order, gramina. The calyx of the hermaphrodite is a biflorous glume; the corolla bivalved; there are three stamina, two styles, and one seed. The calyx and corolla of the male, as in the former, with three stamina. There are eight species.

ISCHURY. See MEDICINE.

ISERTIA, a genus of the hexandria monogynia class and order; the cal. is coloured, four or six toothed; cor. six-cleft, funnel-form; pome subglobular, six-celled. There is one species, a tree of Cayenne.

ISINGLASS, in the materia medica, &c. See ACCIPENSER.

ISNARDIA, a genus of the monogynia order, in the tetrandria class of plants; and in the natural method ranking under the 17th order, calycanthemæ. There is no corolla; the calyx is quadrifid; the capsule quadrilocular, and girt with the calyx. There is one species, an aquatic and annual.

ISOCELES TRIANGLE, in geometry, one that has two equal sides.

ISOCHRONAL, ISOCHRONE, or ISO-

CHRONOUS, is applied to such vibrations of a pendulum, as are performed in the same space of time; as all the vibrations or swings of the same pendulum are, whether the arches it describes are longer or shorter: for when it describes a shorter arch, it moves so much the slower, and when a long one proportionably faster.

ISOCHRONAL LINE, that in which a heavy body is supposed to descend without any acceleration.

ISOETES, a genus of the natural order of filices, belonging to the cryptogamia class of plants. The antheræ of the male flower are within the base of the frons or leaf. The capsule of the female flower is bilocular, and within the base of the leaf. There are two species.

ISOPERIMETRICAL FIGURES, in geometry, are such as have equal perimeters, or circumferences.

1. Of isoperimetrical figures, that is the greatest that contains the greatest number of sides, or the most angles, and consequently a circle is the greatest of all figures that have the same ambit as it has.

2. Of two isoperimetrical triangles, having the same base, whereof two sides of one are equal, and of the other unequal, that is the greater whose two sides are equal.

3. Of isoperimetrical figures, whose sides are equal in number, that is the greatest which is equilateral and equiangular. From hence follows that common problem of making the hedging or walling that will wall in one acre, or even any determinate number of acres, a, fence or wall in any greater number of acres whatever b. In order to the solution of this problem, let the greater number b be supposed a square. Let x be one side of an oblong, whose area is a; then will $\frac{a}{x}$ be the other side; and $2\frac{a}{x} + 2x$ will be the ambit of the oblong, which must be equal to four times the square-root of b; that is, $2\frac{a}{x} + 2x = 4\sqrt{b}$. Whence the value of x may be easily had, and you may make infinite numbers of squares and oblongs that have the same ambit, and yet shall have different given areas, thus

Let $\sqrt{b} = d$,

Then, $\frac{2a + 4xx}{x} = 4d$

$$a + 2xx = 2dx$$

$$2xx - 2dx = -a$$

$$xx - dx = -\frac{a}{2}$$

$$xx - dx + \tfrac{1}{4}dd = -\frac{a}{2} + \tfrac{1}{4}dd$$

$$x = \sqrt{-\frac{a}{2} + \tfrac{1}{4}dd} + \tfrac{1}{2}d.$$

Thus, if one side of the square be 10; and one side of an oblong be 19, and the other 1: then will the ambits of that square and oblong be equal, viz. each 40, and yet the area of the square will be 100, and of the oblong but 19.

ISOPYRUM, in botany; a genus of the polygynia order, in the polyandria class of plants; and in the natural method ranking under the 26th order, multisiliquæ. There is no calyx, but five petals; the nectaria trifid and tubular; the capsules recurved and polyspermous. There are two species, of no note.

ISSUE, in law, has several significations, it being sometimes taken for the children begotten between a man and his wife; sometimes for profits arising from amercements and fines; and sometimes for the profits issuing out of lands or tenements: but this word generally signifies the conclusion, or point of matter, that issues from the allegations and pleas of the plaintiff and defendant in a cause to be tried by a jury or court.

There are two kinds of issues in relation to causes, that upon a matter of fact, and that upon a matter of law: that of fact is where the plaintiff and defendant have fixed upon a point to be tried by a jury: and that in law is where there are a demurrer to a declaration, &c. and a joinder in demurrer, which is determinable only by the judges. Issues of fact are either general or special: they are general, when it is left to the jury to find whether the defendant has done any such thing as the plaintiff has alleged against him; and special, where some special matter, or material point alleged by the defendant in his defence, is to be tried. General issue also signifies a plea in which the defendant is allowed to give the special matter in evidence, by way of excuse or justification; this is granted by several statutes, in order to prevent a prolixity in pleading, by allowing the defendant to give any thing in evidence, to prove that the plaintiff had no cause for his action.

ISSUES *on sheriffs*, are such amercements and fines to the crown, as are levied out of the issues and profits of the lands of sheriffs, for their faults and neglects: but these issues, on shewing a good and sufficient cause, may be taken off before they are estreated into the exchequer.

ISSUES. See SURGERY.

ITEA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The petals are long, and inserted into the calyx; the capsule unilocular and bivalved. There are two species, natives of North America.

IVA, a genus of the pentandria order, in the monœcia class of plants; and in the natural method ranking under the 49th order, compositæ. The male calyx is common and triphyllous; the florets of the disc monopetalous and quinquefid; the receptacle divided by small hairs. There is no female calyx nor corolla; but five florets in the radius; two long styles; and one naked and obtuse seed. There are two species, natives of America.

JUDGE. The judges are the chief magistrates in the law, to try civil and criminal causes. Of these there are twelve in England, viz. the lords chief justices of the courts of king's-bench and common-pleas; the lord chief baron of the exchequer; the three puisne or inferior judges of the two former courts, and the three puisne barons of the latter.

By stat. 1 Geo. III. c. 23. the judges are to continue in their offices during their good behaviour, notwithstanding any demise of the crown (which was formerly held immediately to vacate their seats), and their full salaries are absolutely secured to them during the continuance of their commissions, by which means the judges are rendered completely independant of the king, his ministers, or his successors.

A judge at his creation takes an oath, that he will serve the king, and indifferently administer justice to all men, without respect of persons, take no bribe, give no counsel where he is a party, nor deny right to any, though the king or any other, by letters, or by expressed words, command the contrary, &c. and in default of duty, to be answerable to the king in body, land, and goods.

Where a judge has an interest, neither he nor his deputy can determine a cause, or sit in court; and if he does, a prohibition lies. Hardw. 503.

Judges are punishable for wilful offences, against the duty of their situations; instances of which happily live only in remembrance. There are ancient precedents of judges who were fined when they transgressed the laws, though commanded by warrants from the king.

Judge is not answerable to the king, or the party, for mistakes or errors of his judgment, in a matter of which he has jurisdiction. 1 Salk. 397.

JUDGMENT. The opinion of the judges is so called, and is the very voice and final doom of the law, and therefore is always taken for unquestionable truth; or it is the sentence of the law pronounced by the court, upon the matter contained in the record.

JUDGMENTS are of four sorts, viz. 1. Where the facts are confessed by the parties, and the law determined by the court, which is termed judgment by demurrer.

2. Where the law is admitted by the parties, and the facts only are disputed, as in judgment upon a demurrer.

3. Where both the fact and the law arising thereon are admitted by the defendant, as in case of judgment by confession or default.

4. Where the plaintiff is convinced that fact or law, or both, are insufficient to support his action, and therefore abandons or withdraws his prosecution, as in case of judgment upon a nonsuit or retraxit. See WARRANT OF ATTORNEY.

Judgments are either interlocutory or final.

Interlocutory judgments are such as are given in the middle of a cause, upon some plea, proceeding, or default, which is only intermediate, and does not finally determine or complete the suit; as upon dilatory pleas, when the judgment in many cases is, that the defendant shall answer over; that is, put in a more substantial plea.

Final judgments, are such as at once put an end to the action, by declaring that the plaintiff has either entitled himself, or has not, to recover the remedy he sues for. 3 Black. 398.

JUGERUM, in Roman antiquity, a square of 120 Roman feet; its proportion to the English acre being as 10,000 to 16,097.

JUGLANS, the walnut, a genus of the monœcia class, and polyandria order of plants; and in the natural method ranking under the 50th order, amentaceæ. The male calyx is monophyllous, and squamiform; the corolla divided into six parts; there are 18 filaments: the female calyx is quadrifid, superior; the corolla quadripartite; there are two styles, and the fruit is a plum with a furrowed kernel. There are 8 species, the most remarkable of which is the regia or common walnut. Other two species, called the nigra and alba, or black and white Virginian walnut, are also cultivated in this country, though they are less proper for fruit, having very small kernels.

JUGULAR. See ANATOMY.

JUGULARES, in the Linnæan system, is the name of an order or division of fish, the general character of which is that they have ventral fins. See FISH.

JUJUBES. See MATERIA MEDICA.

JULEP. See PHARMACY.

JULIAN PERIOD. See CHRONOLOGY.

JULUS, a genus of insects, of the order aptera. The generic character is, antennæ moniliform; feelers two, jointed; body subcylindric; legs numerous, twice as many on each side as the segments of the body. The juli are very nearly allied to the scolopendræ or centipedes, but their body, instead of being flattened, as in those insects, is nearly cylindrical; and every joint or segment is furnished with two pair of feet, the number on each side doubling that of the segments, whereas in the scolopendræ the number of joints and of feet is equal on each side. The eyes of the juli are composed of numerous hexagonal convexities, as in the major part of the insect tribe, and the mouth is furnished with a pair of denticulated jaws. These animals, when disturbed, roll themselves up in a flat spiral: their general motion is rather slow and undulatory. The most common species, the julus sabulosus, is often seen in similar situations with the onisci and scolopendræ, and usually measures about an inch and quarter in length: its colour is a polished brownish black, except the legs, which are pale or whitish: it is an oviparous animal, and the young, when first hatched, are very small, of a whitish colour, and are furnished only with three pair of legs, which are situated on each side the superior part, or near the head; the remaining pairs not making their appearance till some days after, when about seven on a side become visible: the rest are gradually acquired till the number is complete, which usually amounts, according to Linnæus, to a hundred and twenty on each side: so long as this species continues in its young or growing state, it is of a pale colour, with a dark-red spot on each side of every segment: in this state it may sometimes be found in the soft mould of hollow trees.

Julus Indus, or great Indian julus, bears an extreme resemblance to the former, but is of such a size as to measure six or seven inches in length: its colour is similar to that of the preceding. It is found in the warmer parts of Asia and America, inhabiting woods and other retired places: the number of legs, according to Linnæus, is a hundred and fifteen on each side, but this seems to be a variable character.

Julus lagurus, or hare-tailed julus, is a very minute and singular species, not exceeding, when at full growth, the eighth of an inch in length. Its colour is pale-brown, and its shape rather broad, and flattish. This insect is by no means uncommon, being seen during the summer months creeping about the barks of trees, walls, &c. It is considered by Linnæus as a species of scolopendra, but as the legs are double the number the segments on each side, it is more properly referred by Degeer, Scopoli, and others, to the present genus. In fact it may be allowed, like the julus complanatus, another slightly flattened species, to form a kind of connecting link between the two genera. The julus terrestris has 100 legs on each side: the body is a polished black. It inhabits most parts of Europe, under stones and in the earth. See Plate Nat. Hist. fig. 234.

JUNCUS, the rush, a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 5th order, tripetaloideæ. The calyx is hexaphyllous; there is no corolla; the capsule is unilocular. There are 29 species, universally known, being very troublesome weeds, and difficult to be eradicated. The pith of two kinds, called the conglomeratus and effusus, or round-headed and soft rushes, is used for wicks to lamps and rushlights. The conglomeratus, and aculus or marine rush, are planted with great care on the banks of the sea in Holland, in order to prevent the water from washing away the earth; which would otherwise be removed every tide, if it was not for the roots of those rushes, which fasten very deep in the ground, and mat themselves near the surface in such a manner as to hold the earth closely together. In the summer-time when the rushes are fully grown, they are cut and tied up in bundles, which are dried, and afterwards carried into the larger towns and cities, where they are wrought into baskets, and several other useful things, which are frequently sent into England. These sorts do not grow so strong in this country as on the Maese, where they sometimes arrive at the height of four feet and upwards.

JUNGERMANNIA, a genus of the natural order of algæ, in the cryptogamia class of plants. The male flower is pedunculated, and naked; the anthera quadrivalved: the female flower is sessile, naked, with roundish seeds. There are 48 species, all natives of Britain, growing in woods, shady places, by the sides of ditches, &c. Many of them are beautiful objects for the microscope.

JUNGIA, a genus of the polygamia segregata order, in the syngenesia class of plants: the common receptacle is chaffy; the perianthium three-flowered; the florets tubular, two-lipped; the exterior lip ligulate; the interior one bipartite. There is one species, a native of S. America.

JUNIPERUS, the juniper tree; a genus of the monadelphia order, in the monœcia class of plants; and in the natural method ranking under the 51st order, coniferæ. The male amentum is a calyx of scales; there is no corolla; three stamina: the female calyx tripartite; there are three petals, and as many styles; the berry is trispermous, and equal, by means of three tubercles of the indurated calyx adhering to it. There are 12 species; the most remarkable are, 1. The communis, or common juniper, grows naturally in many parts of Britain upon dry barren commons, where it seldom rises above the height of a low shrub, which grows naturally only in dry, chalky, or sandy land. Of this species there is a variety called Swedish juniper, which grows ten or twelve feet high, very branchy the whole length, with the branches growing more erect, and leaves, flowers, and fruit, like the former. 2. The oxycedrus, or Spanish juniper, rises from ten to fifteen feet high, closely branched from bottom to top; having short, awl-shaped, spreading leaves by threes, and small diœcious flowers, succeeded by large reddish-brown berries. 3. The thurifera, or blue-berried Spanish juniper, grows twenty feet high or more. 4. The Virginiana, or Virginia cedar, grows thirty or forty feet high, branching from bottom to top in a conic manner. 5. The Lycia, Lycian cedar, or olibanum tree, grows twenty feet high. 6. The Phœnicia, or Phœnician cedar, grows about twenty feet high. It is a native of Portugal. 7. The Bermudiana, or Bermudian cedar, grows twenty or thirty feet high. 8. The sabina, or savin tree; of which there are three varieties, the spreading, upright, and variegated savin. The propagation of all the junipers is by seed, and of the savins by layers and cuttings.

Juniper-berries have a strong, not disagreeable smell; and a warm, pungent, sweet taste, which, if they are long chewed, or previously well bruised, is followed by a bitterish one. The pungency seems to reside in the bark; the sweet in the juice; the aromatic flavour in oily vesicles spread through the substance of the pulp, and distinguishable even by the eye; and the bitter in the seeds.

JURY. This strong tower of defence of the British constitution, which is one of the leading features of the Magna Charta, is composed of a certain number of persons sworn to enquire of, and try some fact, and declare the truth upon the evidence brought before them.

In criminal cases juries are divided into grand and petty. The grand jury must be all freeholders, but it does not appear that any specific estate has been determined to be necessary; before them the charge is laid, and unless twelve or more of them are of opinion that it is well founded, the accusation is dismissed; which they call not finding a true bill. If they find a true bill, it must afterwards be confirmed by the unanimous suffrage of a petty jury of 12 men upon whom no suspicion of partiality can possibly rest.

In civil cases juries are divided into common and special. The latter are generally employed in cases where any difficulties with respect to commercial transactions arise, and are best decided by a special jury of merchants.

To obtain a special jury, a motion is made in court, and rule granted, for the sheriff to attend the master, prothonotary, or other proper officer, with his freeholders' book, in the presence of the attorneys on both sides, and to take indifferently forty-eight freeholders, when each party strikes off twelve, and the remaining twenty-four are returned upon the pannel.

A common jury is one returned by the sheriff according to the directions of 3 Geo. II. c. 25. which appoints that the sheriff shall not return a separate pannel for every cause, but the same for every cause to be tried at the same assizes, containing not less than forty-eight, nor more than seventy-two; and that their names being written on tickets, shall be put into a box, and when the cause is called, twelve whose names shall be first drawn shall be sworn, unless absent, challenged, or excused. They are then sworn to give a true verdict according to the evidence, unless they are challenged.

Challenges are of two kinds: challenges to the array, and challenges to the poll. Challenges to the array are an exception to the whole pannel. Challenges to the poll are exceptions to particular jurors, and are reduced to four heads by sir Edward Coke.

1. Propter honoris respectum; as a lord of parliament may be challenged by both parties, or challenge himself.

2. Propter defectum. If a juryman is an alien-born, or if he is a slave or bondman, they are defects; but the principal deficiency is want of a sufficient estate, which is now ten pounds per annum in England, and six pounds in Wales, of freehold or copyhold lands; and any leaseholder for the term of five hundred years, or any term determinable upon life or lives of the clear yearly value of twenty pounds per annum above the rent, is qualified.

3. Propter affectum. When the juror may be suspected of partiality.

4. Propter delictum. For some crime or misdemeanor that affects the juror's credit, and renders him infamous.

The service of jurymen is also sometimes excused; as sick and decrepid persons, persons not commorant in the county, men above seventy years old, and infants; physicians, counsel, attorneys, officers of the courts, and the like. Clergymen are also usually excused, but are liable in respect of their lay fees, unless they are in the service of the king, or some bishop.

In criminal cases, when the prisoner has put himself upon the country, the sheriff returns a pannel of unexceptionable freeholders of the county where the fact is committed.

In these cases, at least in capital ones, challenges may be made not only on the accounts before mentioned, both to the array or to the polls on the parts of the king and prisoner, but the prisoner is allowed a kind of peremptory challenge (which is now limited to twenty persons), without shewing any cause at all. This privilege is denied to the king, who must assign a reason for the challenge.

If by reason of challenges, or in default of the jurors, a sufficient number cannot be had of the original pannel, a tales may be awarded both in civil and criminal cases, that is, a sufficient number of persons present in court to be joined to the other jurors, who are however liable to the same challenges as the principal jurors.

The jury, after the proofs are summed up, unless the case is very clear, retire to consider, and are kept without meat, drink, fire, or candle, till they are unanimously agreed. If the jury eat or drink, or have victuals about them, without the consent of the court, before the verdict, it is finable; and if they do it at the charge of him for whom they find, the verdict will be set aside. Also if they speak with either of the parties, or their agents, after they are gone from the bar, or if they receive any fresh evidence, or cast lots to prevent dispute, the verdict is bad.

When the jury have delivered their verdict, and it is recorded in court, they are dismissed.

A jury when either party is an alien-born, shall be half denizens, and the other aliens (if there are so many in the place); but when both parties are aliens, it is presumed there is no more partiality for the one than the other, and therefore it was resolved the jury shall all be denizens.

If a juror receives a bribe from either party, he shall forfeit ten times as much as he has taken, half to the king, and half to him who sues.

A man who threatens or assaults a juror for giving a verdict against him, is punishable by fine and imprisonment; and if he strikes him in court in the presence of the judge, he shall lose his hand and his goods, and the profits of his land during life, and suffer perpetual imprisonment.

IVORY, ebur, in natural history, &c. a hard, solid, and firm substance, of a white colour, and capable of a very good polish. It is the tusk of the elephant, and is hollow from the base to a certain height, the cavity being filled up with a compact medullary substance, seeming to have a great number of glands in it. It is observed that the Ceylon ivory, and that of the island of Achem, do not become yellow in the wearing, as all other ivory does; for this reason the teeth of these places bear a larger price than those of the coast of Guinea.

To soften ivory and other bones, lay them for twelve hours in aqua fortis, and then three days in the juice of beets, and they will become so soft that they may be worked into any form. To harden them again, lay them in strong vinegar. Dioscorides says, that by boiling ivory for the space of six hours with the root of mandragoras, it will become so soft that it may be managed as one pleases.

IVORY-*black* is the coal of ivory or bone formed by great heat, while deprived of all access of air.

JUPITER, in astronomy, one of the superior planets, remarkable for its great brightness. See ASTRONOMY.

JURY-MAST, whatever is set up in room of a mast that has been lost in a storm or in an engagement, and to which a lesser yard, ropes, and sails, are fixed.

JUSSIEA, a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 17th order, calycanthemæ. The calyx is quadripartite, or quinquepartite superior; there are four or five petals; the capsule quadrilocular or quinquelocular, oblong, opening at the angles: the seeds are numerous and small. There are 11 species, mostly herbaceous plants of the W. Indies.

JUSTICE, in a legal sense, a person deputed by the king to administer justice to his subjects, whose authority arises from his deputation, and not by right of magistracy.

In the courts of king's bench and common pleas there are two judges styled chief justices, each of whom retains the title of lord during the time of his continuing in office. The first of these, who is styled lord chief justice of England, has a very extensive power and jurisdiction in pleas of the crown. He hears all pleas in civil causes brought before him in the court of king's bench, and also the pleas of the crown; while, on the other hand, the lord chief justice of the common pleas has the hearing of all civil causes between common persons. Besides the lords chief justices, there are in each of the above courts three puisne justices; there are also several other justices appointed by the king for the execution of the laws; such as the lords justices in eyre of the forests, who are two justices appointed to determine all offences committed in the king's forests; justices of assize, of oyer and terminer, of gaol-delivery, &c. They are also called justices of nisi prius, and so denominated from the words used in a common form of adjournment of a cause in the court of common pleas. See NISI PRIUS, OYER and TERMINER, COMMON PLEAS, and KING'S BENCH.

JUSTICES *of the Peace*. See PEACE.

JUSTICIARY, or court of JUSTICIARY, in Scotland, a court of supreme jurisdiction in all criminal cases.

This court came in place of the justice-eyre or justice-general, which last was taken away by parliament in 1672, and was erected into a justice or criminal court, consisting of a justice-general alterable at the monarch's pleasure, justice clerk, and five other judges, who are lords of session.

This court commonly sits upon Mondays, and has an ordinary clerk, who has his commission from the justice-clerk. They have four macers, and a doomster appointed by the lords of the session.

The form of the process is this: the clerk raises a libel or indictment upon a bill passed by any of the lords of that court, at the instance of the pursuer, against the defendant or criminal, who is immediately committed to prison after citation. When the party, witnesses, great assize, or jury of forty-five men, are cited, the day of compearance being come, fifteen of the great assize are chosen to be the assize upon the pannel, or prisoner at the bar. The assize sits with the judges to hear the libel read, witnesses examined, and the debates on both sides, which are written verbatim in the adjournal books. The king's advocate pleads for the pursuer, being the king's cause, and other advocates for the pannel. The debates being closed, the judges find the libel or indictment either non-relevant, in which case they desert the diet, and assoil or absolve the party accused; or, if relevant, then the assize or jury of fifteen is removed into a closer room, none being present with them, where they choose their chancellor and clerk, and consider the libel, deposition, and debates; and bring in their verdict of the pannel sealed, guilty or not guilty: if not guilty, the lords absolve; if guilty, they condemn and declare their sentence of condemnation, and command the sentence to be pronounced against the pannel by a macer and the mouth of the doomster. The lords of the justiciary likewise go circuits twice a year into the country. See the article CIRCUIT.

JUSTICIES, a writ directed to a sheriff, by virtue of which he is empowered to hold a plea of debt in his county-court for a sum above 40*s*. though by his ordinary power he has only cognizance of sums under 40*s*.

JUSTIFICATION, in law, is an affirming or shewing good reason in court, why one does such a thing as he is called to answer; as to justify in a cause of a replevin.

IVY. See HEDERA.

IXIA, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the sixth order, ensatæ. The corolla is hexapetalous, patent, and equal; there are three stigmata, a little upright and petalous. There are fifty-four species, consisting of herbaceous, tuberous, and bulbous-rooted flowery perennials, from one to two feet high, terminated by hexapetalous flowers of different colours. They are propagated by offsets, which should be taken off in summer at the decay of the leaves: but as all the plants of this genus are natives of warm climates, few of them can bear the open air of this country in winter.

IXORA, a genus of the tetrandria monogynia class of plants. The corolla consists of a single petal; the tube is cylindric, very long and slender; the limb is plane, and divided into four oval segments; the fruit is a berry of a roundish figure, with only one cell; the seeds are four in number, convex on one side, and angular on the other. There are nine species, very ornamental shrubs for the stove.

JUSTICIA, Malabar nut; a genus of the monogynia order, in the diandria class of plants; and in the natural method ranking under the 40th order, personatæ. The corolla is ringent; the capsule bilocular, parting with an elastic spring at the heel; the stamina have only one anthera. There are eighty species, most of them natives of the East Indies, growing many feet high; some adorned with fine large leaves, others with small narrow ones, and all of them with monopetalous ringent flowers. Only two species are commonly cultivated in our gardens, viz. the adhatoda, or common Malabar nut, and the hyssopifolia or snap-tree. The first grows ten or twelve feet high, with a strong woody stem; and from the ends of the branches short spikes of white flowers, with dark spots, having the helmet of the corolla concave. The second has a shrubby stem, and white flowers, commonly by threes, from the sides of the branches; succeeded by capsules, which burst open with elastic force for the discharge of the seeds; whence the name of snap-tree.

JYNX, the wryneck, a genus of birds belonging to the order of picæ; the characters of which are, that the bill is slender, round, and pointed; the nostrils are concave and naked; the tongue is very long, very slender, cylindric, and terminated by a hard point; and the feet are formed for climbing. There is only one species, viz. the torquilla. The colours of this bird are elegantly pencilled, though its plumage is marked with the plainest colours. The wryneck, Mr. Pennant apprehends, is a bird of passage, appearing with us in the spring before the cuckoo. Its note is like that of the kestril, a quick-repeated squeak; its eggs are white, with a very thin shell; it builds in the hollows of trees, making its nest of dry grass. It has a very whimsical way of turning and twisting its neck about, and bringing its head over its shoulders, whence it had its Latin name torquilla, and its English one of wryneck.

K.

K, or k, the tenth letter of our alphabet; as a numeral, denotes 250; and with a line over it, K, 250000.

KÆMPFERIA, *zedoary*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the eighth order, scitamineæ. The corolla is sexpartite, with three of the segments larger than the rest, patulous; and one only bipartite. The species are, 1. The galanga, common galangal, or long zedoary. 2. The rotunda, or round zedoary. Both are perennial in root; but the leaves rise annually in spring, and decay in winter. They flower in summer; each flower is of one petal, tubulous below, but plain above, and divided into six parts; they continue three or four weeks in beauty, but are never succeeded by seeds in this country. Both these plants must be potted in light rich mould, and always kept in the hot-house.

KALI, a genus of marine plants, which are burnt to procure mineral alkali.

KALMIA, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 18th order, bicornes. The calyx is quinquepartite; the corolla salver-shaped, formed with five nectariferous horns on the under or outer side; the capsule quinquelocular. Of this genus there are four species. Those chiefly in cultivation with us are,

1. The latifolia, a most beautiful shrub, which rises usually to the height of five or six feet, and sometimes twice that height in its native places. The flowers grow in bunches on the tops of the branches to footstalks three inches long; they are white, stained with purplish red, consisting of one petal in form of a cup, divided at the verge into five sections; in the middle are a stylus and 12 stamina, which, when the flower first opens, appear lying close to the sides of the cup at equal distances, their apices being lodged in 10 little hollow cells, which being prominent on the outside, appear as so many little tubercles. This plant is a native of Carolina, Virginia, and other parts of the northern continent of America, yet is not common, but found only in particular places; it grows on rocks hanging over rivulets and running streams, and on the sides of barren hills.

2. The angustifolia, rises to the height of about 16 feet, with evergreen leaves. The flowers grow in clusters, and when blown, appear white; but on a near view, are of a faint blueish colour, which as the flower decays grows paler.

KAOLIN, the name of an earth which is used as one of the two ingredients in oriental porcelain. See PORCELAIN.

KECKLE, or KECKLING, in the sea language, is the winding of old ropes about cables, to prevent them from galling.

KEDGING, in the sea-language, is when a ship is brought up or down a narrow river by means of the tide, the wind being contrary.

KEEL, the lowest piece of timber in a ship, running her whole length from the lower part of her stem to the lower part of her stern-post. Into it are all the lower futtocks fastened; and under part of it, a false keel is often used.

KEELSON, a principal timber in a ship, fayed withinside cross all the floor-timbers; and being adjusted to the keel with suitable scarfs, it serves to strengthen the bottom of the ship.

KEEP, in antient military history, a kind of strong tower which was built in the centre of a castle or fort, to which the besieged retreated, and made their last efforts of defence. Of this description is the keep of Windsor castle.

KEEPER *of the great seal*, is a lord by his office, is styled lord-keeper of the great seal of Great Britain, and is always one of the privy council. All grants, charters, and commissions of the king under the great seal, pass through the hands of the lord-keeper, for without that seal many of those grants, &c. would be of no force, the king being, in the interpretation of the law, a corporation, and therefore passing nothing but by the great seal, which is also said to be the public faith of the kingdom, being in the highest esteem and reputation. Whenever there is a lord-keeper, he is invested with the same place, authority, pre-eminence, jurisdiction, or execution of laws, as the lord chancellor of Great Britain is vested with.

KEEPER *of the privy seal*. See PRIVY-SEAL.

KEISELSCHIEFER. This mineral occurs usually in blocks and amorphous masses of different sizes; very often in the beds of rivers: colour various shades of grey: structure slaty: usually opaque: brittle: specific gravity from 2.880 to 2.415: infusible per se. This species is divided into two subspecies.

Keiselschiefer, common: colour blackish grey or greenish: often traversed by veins of quartz: surface smooth: texture compact: fracture splintery, or imperfectly conchoidal: composed according to Wiegleb of

75.00	silica
10.00	lime
4.58	magnesia
3.54	iron
5.02	inflammable matter
98.14	

Lydian stone is another species of keiselschiefer: commonly intersected by veins of quartz: fracture even: sometimes inclining to conchoidal: specific gravity 2.596: powder black: colour greyish black.

This, or a stone similar to it, was used by the antients as a touchstone. They drew the metal to be examined along the stone, and judged of its purity by the colour of the metallic streak. On this account they called it βασανος, "the trier." They called it also Lydian stone, because, as Theophrastus informs us, it was found most abundantly in the river Tmolus in Lydia.

KELP, in the glass trade, a term used for a sort of potass made use of in many of the glass works, particularly for the green glass. It is the calcined ashes of a plant called by the same name; and in some places of sea-tangs or-laces, a sort of thick-leaved fucus or sea-wrack. This plant is thrown on the rocks and shores in great abundance, and in the summer months is raked together and dried as hay in the sun and wind, and afterwards burned to the ashes called kelp.

KEMO, a shell found on the coast of Sumatra; it is sometimes three or four feet in diameter, as white as ivory. See Marsden's Hist. of Sumatra.

KENKS, in the sea-language, doublings in a rope or cable, when handed in and out, so that it does not run easy; or when any rope makes turns or twists, and does not run free in the block.

KERATOPHYTUM, in natural history. See CORALLINES.

KERMES. See COCCUS.

KERMES MINERAL, a compound of sulphuret of antimony and potass.

KETCH, in naval architecture, a vessel with two masts, usually applied to one carrying bombs, or rather mortars.

KEVEL, in ship-building, a piece of plank fayed against the quickwork on the quarter-deck, in the shape of a semicircle; about which the running rigging is belaid.

KEY, in music, a fundamental note or tone to which the whole of a movement has a certain relation or bearing, to which all its modulations are referred and accommodated, and in which it both begins and ends. There are but two species of keys, one of the major, and one of the minor mode; all the keys in which we employ sharps or flats being deduced from the natural keys of C major, and A minor, of which indeed they are only transpositions.

KEY-STONE. See ARCHITECTURE.

KEYS. See ORGAN, HARPSICHORD, &c.

KIDNAPPING, is the forcible taking and carrying away a man, woman, or child, from their own country, and sending them to another. This is an offence at common law, and punishable by fine, imprisonment, and pillory.

By stat. 11 and 12 W. III. c. 7, if any captain of a merchant vessel shall during his being abroad force any person on shore, and wilfully leave them behind, or refuse to bring home all such men as he carried out, if able and desirous to return, he shall suffer three months imprisonment. Exclusive of the above punishment for this as a criminal offence, the party may recover upon an action for compensation in damages for the civil injury.

KIDNEYS. See ANATOMY.

KIFFEKIL. This mineral is dug up near Konie in Natolia, and is employed in forming the bowls of Turkish tobacco-pipes. The sale of it supports a monastery of dervises established near the place where it is dug. It is found in a large fissure six feet wide, in grey calcareous earth. The workmen assert that it grows again in the fissure, and puffs itself up like froth. This mineral, when fresh dug, is of the consistence of wax; it feels soft and greasy; its colour is yellow; its specific gravity 1.600: when thrown on the fire it sweats, emits a fetid vapour, becomes hard, and perfectly white.

According to the analysis of Klaproth, it is composed of 50.50 silica

50.50	silica
17.25	magnesia
25.00	water
5.00	carbonic acid
.50	lime.
98.25	

KIGGELARIA, a genus of the decandria order, in the dioecia class of plants, and in the natural method ranking under the 37th order, columniferæ. The male calyx is quinquepartite; the corolla pentapetalous; there are five trilobous glandules; the antheræ are perforated at top; the female calyx and corolla as in the male; there are five styles; the capsule unilocular, quinquevalved, and polyspermous. There is but one species, viz. the Africana. As this is a native of warm climates, it must be constantly kept in a stove in this country. It is propagated by seeds, layers, or cuttings, though most readily by seeds.

KILDERKIN, a liquid measure containing two firkins, or 18 gallons.

KINDRED. See DESCENT.

KING, signifies him who has the highest power and absolute rule over the whole land; and therefore the king is, in intendment of law, cleared of those defects which common persons are subject to; for he is always supposed to be of full age, though ever so young. He pardons life and limb to offenders against the crown and dignity, except such as he binds himself by oath not to forgive. The law ascribes to his majesty, in his political capacity, an absolute immortality. The king never dies. For immediately on the decease of the reigning prince in his natural capacity, his imperial dignity, by act of law, without any interregnum or interval, is vested at once in his heir, who is eo instanti king to all intents and purposes. And so tender is the law of supposing even a possibility of his death, that his natural dissolution is generally called his demise, an expression signifying merely a transfer of property. Plowd. 177.

By the articles of the union of the two kingdoms of England and Scotland, all papists, and persons marrying papists, are for ever excluded from the imperial crown of Great Britain; and in such case, the crown shall descend to such person being a protestant, as should have inherited the same, in case such papist, or person marrying a papist, was naturally dead. 5 Anne, c. 8.

KING'S BENCH. The king's bench is the supreme court of common law in the kingdom, and is so called because the king used to sit there in person; it consists of a chief justice, and three puisne justices, who are by their office the sovereign conservators of the peace, and supreme coroners of the land.

This court has a peculiar jurisdiction, not only over all capital offences, but also over all other misdemeanours of a public nature, tending either to a breach of the peace, or to oppression, or faction, or any manner of misgovernment. It has a discretionary power of inflicting exemplary punishment on offenders, either by fine, imprisonment, or other infamous punishment, as the nature of the crime, considered in all its circumstances, shall require.

The jurisdiction of this court is so transcendant, that it keeps all inferior jurisdictions within the bounds of their authority; and it may either remove their proceedings to be determined here, or prohibit their progress below: it superintends all civil corporations in the kingdom; commands magistrates and others to do what their duty requires, in every case where there is no specific remedy; protects the liberty of the subject, by speedy and summary interposition; takes cognizance both of criminal and civil causes; the former in what is called the crown side, or crown office; the latter in the plea side of the court.

This court has cognizance on the plea side of all actions of trespass, or other injury alleged to be committed vi et armis; of actions for forgery of deeds, maintenance, conspiracy, deceit, and actions on the case which allege any falsity or fraud.

In proceedings in this court, the defendant is arrested for a supposed trespass, which in reality he has never committed; and being thus in the custody of the marshal of this court, the plaintiff is at liberty to proceed against him for any other personal injury, which surmise of being in the custody of the marshal, the defendant is not at liberty to dispute.

This court is likewise a court of appeal, into which may be removed, by writ of error, all determinations of the court of common pleas, and of all inferior courts of record in England.

KING'S BENCH PRISON. King's bench new rules. East. 30 G. III. it is ordered by the court, that from and after the first day of Trinity term next, the rule made in the sixth year of the reign of king George I. and all other rules for establishing the rules of the king's bench prison, shall be, and the same are hereby, repealed. And it is further ordered, that from and after the said first day of Trinity term next, the rules of the king's bench prison shall be comprized within the bounds following, exclusive of the public houses hereinafter mentioned; that is to say, from Great Cumber-court in the parish of St. George the Martyr, in the county of Surry, along the north side of Dirty-lane, and Melancholy-walk, to Blackfriars'-road, along the western side of the said road to the obelisk, and thence along the south-west side of the London-road, round the direction post in the centre of the roads, near the public house known by the sign of the Elephant and Castle, and thence along the eastern side of Newington causeway to Great Cumber-court aforesaid: and it is also ordered, that the new gaol Southwark, and the highway, exclusive of the houses on each side of it, leading from the king's bench prison to the said new gaol, shall be within and part of the said rules. And it is lastly ordered, that all taverns, victualling-houses, ale-houses, and wine-vaults, and houses or places licensed to sell gin, or other spirituous liquors, shall be excluded out of, and deemed no part of the said rules. It is ordered, that from and after the first day of Trinity term next, no prisoner in the king's bench prison, or within the rules thereof, shall have, or be entitled to have, day rules above three days in each term. And it is further ordered, that every such prisoner having a day rule, shall return within the walls or rules of the said prison, at or before nine o'clock in the evening of the day on which such rule shall be granted.

KING'S PALACE. The limits of the king's

palace at Westminster extend from Charing-cross to Westminster-hall, and shall have such privileges as the antient palaces. 28 H. VIII. c. 12.

King'sfisher. See Alcedo.

KLINGSTEIN: this mineral composes whole mountains. They are usually insulated; and like basalt, shew a tendency to assume the form of four-sided prisms. Its colour is usually deep grey, of various shades; but most commonly greenish. Sometimes various shades appear together, which gives it the appearance of being spotted. Found not only constituting mountains, but also in globular masses, &c. Internal lustre arises chiefly from some crystals of hornblende and felspar which it contains. Structure slaty. Texture compact. Fracture usually splintery; sometimes conchoidal. Brittle. Gives a clear sound when struck with a hammer. Specific gravity 2.575. Powder light grey. Melts easily into a glass. A specimen analysed by Klaproth yielded 57.25 silica

57.25	silica
23.50	alumina
2.75	lime
3.25	oxide of iron
0.25	oxide of manganese
8.10	soda
3.00	water.
98.10	

KLEINHOVIA, a genus of the class and order gynandria decandria: the calyx is five-leaved; corolla five-petalled; nect. bell-shaped; caps. inflated, five-lobed. There is one species, a tree of Java.

KNAPSACK, a rough leather or canvas bag, which is strapped to an infantry soldier's back when he marches, and which contains his necessaries. Square knapsacks are supposed to be most convenient. They should be made with a division to hold the shoes, blacking-balls, and brushes, separate from the linen. White goat-skins are sometimes used; but we do not conceive them to be equal to the painted canvas ones. Soldiers are put under stoppages for the payment of their knapsacks, which after six years become their property.

KNAUTIA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 48th order, aggregatæ. The common calyx is oblong, simple, quinqueflorous; the proper one simple, superior; the florets irregular; the receptacle naked. There are four species, chiefly annuals of the Levant.

KNEE. See Anatomy.

Knee, in a ship, a crooked piece of timber, bent like a knee, used to bind the beams and futtocks together, by being bolted fast into them both. These are used about all the decks.

KNEES, *carling*, in a ship, those timbers which extend from the sides to the hatchway, and bear up the deck on both sides.

KNIGHT, properly signifies a person, who, for his virtue and martial prowess, is by the king raised above the rank of gentleman into a higher class of dignity and honour. The ceremonies at the creation of knights have been various; the principal was a box on the ear, and a stroke with a sword on the shoulder; they put on him a shoulder-belt, and a gilt sword, spurs, and other military accoutrements; after which, being armed as a knight, he was led to the church in great pomp. Camden describes the manner of making a knight-bachelor among us, which is the lowest, though the most antient order of knighthood, to be thus: the person kneeling was gently struck on the shoulder by the prince, and accosted in these words, "rise," or "be a knight in the name of God." For the several kinds of knights among us, see Banneret, Baronet, Bath, Garter, &c.

KNIGHTS *of the shire*, or Knights *of parliament*, in the British polity, are two knights or gentlemen of estate, who are elected, on the king's writ, by the freeholders of every county, to represent them in parliament. The qualification of a knight of the shire is to be possessed of 600*l*. per ann. in a freehold estate. Their expences during their sittings were by a statute of Henry VIII. to be defrayed by the county; but this is now never required.

Knight-marshal, an officer in the king's household, who has jurisdiction and cognizance of any transgression within the king's household and verge; as also of contracts made there, whereof one of the house is party.

Knights, in a ship, two thick short pieces of wood, commonly carved like a man's head, having four shivers in each, three for the halyards, and one for the top-ropes to run in; one of them stands fast bolted on the beams abaft the foremast, and is therefore called the fore-knight; and the other, standing abaft the mainmast, is called the main-knight.

KNOXIA, a genus of the class and order tetrandria monogynia. The corolla is one-petalled, funnel-form; seeds two-grooved. There is one species, a herb of Ceylon.

KOENIGIA, a genus of the trigynia order, belonging to the triandria class of plants. The calyx is triphyllous; there is no corolla, and but one ovate and naked seed.

KORAN. See Alcoran.

KUPFERNICKEL, is a sulphuret of nickel, and is generally compounded of nickel, arsenic, and sulphuret of iron.

KURTUS, a genus of fishes of the order jugulares; the generic character of which is, body broad, carinated both above and below, with greatly elevated back; gill-membrane two-rayed. The genus kurtus, instituted by Dr. Bloch, consists at present of a single species only. This is a native of the Indian seas; and is supposed to feed on shell-fish, small cancri, and other sea insects, the remains of which were observed in the stomach of the specimen examined by Dr. Bloch. The length of this fish was about ten inches, including the tail, and its greatest breadth something more than four inches; its shape is deep or broad, the sides being much compressed, and the back rising very high in the middle. The colour of the whole body is silvery, as if covered with foil, without any appearance of scales; the back is tinged with gold-colour and marked by three or four black spots on its ridge, and the fins have a reddish cast.

L.

L, or l, the eleventh letter of our alphabet, as a numeral, denotes 50; and with over it, thus, L̄, 50000.

LA, in music, the syllable by which Guido denoted the last sound of each hexachord: if it begins in C, it answers to our *A*; if in G to E; and if in F to D.

LABARUM, in Roman antiquity, the standard borne before the Roman emperors; being a rich purple streamer, supported by a spear.

LABDANUM, or Ladanum. This resin is obtained from the cystus creticus, a shrub which grows in Syria and the Grecian islands. The surface of the shrub is covered with a viscid juice, which when concreted forms ladanum. It is collected while moist by drawing over it a kind of rake with thongs fixed to it; from these it is afterwards scraped with a knife. The best is in masses almost black, and very soft, having a fragrant odour and a bitterish taste. When dissolved in alcohol, it leaves behind it a little gum. The specific gravity of this resin is about 1.18. See Resins.

LABEL, in heraldry, a fillet usually placed in the middle along the chief of the coat, without touching its extremities.

Label of a circumferentor, a long thin brass ruler, with a sight at one end, and a centre-hole at the other; chiefly used with a tangent line to take altitudes.

LABORATORY and *Apparatus*, chemical. A chemical laboratory, though extremely useful, and even essential to all who embark extensively in the practice of chemistry, either as an art, or as a branch of liberal knowledge, is by no means required for the performance of those simple experiments which furnish the evidence of the fundamental truths of the science. A room that is well lighted, easily ventilated, and destitute of any valuable furniture, is all that is absolutely necessary for the purpose. It is even advisable that the construction of a regular laboratory should be deferred till the student has made some progress in the science; for he will then be better qualified to accommodate its plan to his own peculiar views and convenience.

It is scarcely possible to offer the plan of a laboratory, which will be suitable to every person, and to all situations; or to suggest any thing more than a few rules that should be generally observed. Different apartments are required for the various classes of chemical operations. The principal one may be on the ground floor; twenty-five feet long, fourteen or sixteen feet wide, and open to the roof, in which there should be contrivances for allowing the occasional escape of suffocating vapours. This will be destined chiefly for containing furnaces, both fixed and portable. It should be amply furnished with shelves and drawers, and with a large table in the centre, the best form of which is that of a double cross. Another apartment may be appropriated to the minuter operations of chemistry; such as those of precipitation on a small scale, the processes that require merely the heat of a lamp, and experiments on the gases. In a third, of smaller size, may be deposited accurate balances, and other instruments of considerable nicety, which would be injured by the acid fumes that are constantly spread through a laboratory.

The following are the principal instruments that are required in chemical investigations; but it is impossible, without entering into very tedious details, to enumerate all that should be in the possession of a practical chemist.

1. Furnaces. These may either be formed of solid brick-work, or of such materials as admit of their removal from place to place. See FURNACE, and CHEMISTRY.

2. For containing the materials, which are to be submitted to the action of heat in a wind furnace, vessels called crucibles are employed. They are most commonly made of a mixture of fire-clay and sand, occasionally with the addition of plumbago, or black lead. The Hessian crucibles are best adapted for supporting an intense heat without melting; but they are liable to crack when suddenly heated or cooled. The porcelain ones made by Messrs. Wedgewood, are of much purer materials, but are still more apt to crack on sudden changes of temperature; and when used, they should therefore be placed in a common crucible of larger size, the interval being filled with sand. The black-lead crucibles resist very sudden changes of temperature, and may be repeatedly used; but they are destroyed when some saline substances (such as nitre) are melted in them, and are consumed by a current of air. For certain purposes crucibles are formed of pure silver or platina. Their form varies considerably; but it is necessary, in all cases, to raise them from the bars of the grate, by a stand. For the purpose of submitting substances to the continued action of a red heat, and with a considerable surface exposed to the air, a hollow arched vessel, with a flat bottom, termed a muffle, is commonly used. See CHEMISTRY.

3. Evaporating vessels should always be of a flat shape, so as to expose them extensively to the action of heat. They are formed of glass, of earthenware, and of various metals. Those of glass are with difficulty made sufficiently thin, and are often broken by changes of temperature; but they have a great advantage in the smoothness of their surface, and in resisting the action of most acid and corrosive substances. Evaporating vessels of porcelain, or Wedgwood's ware, are next in utility, are less costly, and less liable to be cracked. They are made both of glazed and unglazed ware. For ordinary purposes, the former are to be preferred: but the unglazed should be employed when great accuracy is required, since the glazing is acted on by several chemical substances. Evaporating vessels of glass, or porcelain, are generally bedded up to their edge in sand; but those of various metals are placed immediately over the naked fire. When the glass or porcelain vessel is very thin, and of small size, it may be safely placed on the ring of a brass stand, and the flame of an Argand's lamp, cautiously regulated, may be applied beneath it. A lamp thus supported, so as to be raised or lowered at pleasure, on an upright pillar, to which rings of various diameters are adapted, will be found extremely useful; and when a strong heat is required, it is advisable to employ a lamp provided with double concentric wicks.

4. In the process of evaporation, the vapour for the most part is allowed to escape; but in certain chemical processes, the collection of the volatile portion is the principal object. This process is termed distillation. See DISTILLATION.

The common still, however, can only be employed for volatilizing substances that do not act on copper, or other metals, and is, therefore, limited to very few operations, and on that account alembics and retorts are necessary. See CHEMISTRY.

In several instances, the substance raised by distillation, is partly a condensible liquid, and partly a gas, which is not condensed till it is brought into contact with water. To effect this double purpose, a series of receivers termed Woulfe's apparatus is employed. See CHEMISTRY.

When a volatile substance is submitted to distillation, it is necessary to prevent the escape of the vapour through the junctures of the vessels; and this is accomplished by the application of lutes. The most simple method of confining the vapour, it is obvious, would be to connect the places of juncture accurately together by grinding; and accordingly the neck of the retort is sometimes ground to the mouth of the receiver. This, however, adds too much to the expence of apparatus to be generally practised.

When the distilled liquid has no corrosive property, (such as water, alcohol, ether, &c.) slips of moistened bladder, or of paper or linen spread with flour paste, white of egg, or mucilage of gum Arabic, sufficiently answer the purpose. The substance which remains, after expressing the oil from bitter almonds, and which is sold under the name of almond meal or flour, forms a useful lute, when mixed to the consistency of glaziers' putty, with water or mucilage.

For confining the vapour of acid or highly corrosive substances, the fat lute is well adapted. It is formed by beating perfectly dry and finely-sifted tobacco-pipe clay with painters' drying-oil, to such a consistence that it may be moulded by the hand. The same clay, beaten up with as much sand as it will bear without losing its tenacity, with the addition of cut tow, or of horse-dung, and a proper quantity of water, furnishes a good lute, which has the advantage of resisting a considerable heat, and is applicable in cases where the fat lute would be melted or destroyed. Various other lutes are recommended by chemical writers; but the few that have been enumerated are found to be amply sufficient for every purpose. See LUTE.

On some occasions, it is necessary to protect the retort from too sudden changes of temperature by a proper coating. For glass retorts, a mixture of common clay or loam with sand, and cut shreds of flax, may be employed. If the distillation is performed by a sand heat, the coating needs not to be applied higher than that part of the retort which is bedded in sand; but if the process is performed in a wind furnace, the whole body of the retort, and that part of the neck also which is exposed to heat, must be carefully coated. To this kind of distillation, however, earthen retorts are better adapted; and they may be covered with a composition originally recommended by Mr. Willis. Two ounces of borax are to be dissolved in a pint of boiling water, and a sufficient quantity of slaked lime added to give it the thickness of cream. This is to be applied by a painter's brush, and allowed to dry. Over this a thin paste is afterwards to be applied, formed of slaked lime and common linseed-oil, well mixed and perfectly plastic. In a day or two, the coating will be sufficiently dry to allow the use of the retort.

For joining together the parts of iron vessels used in distillation, a mixture of the finest China clay, with solution of borax, is well adapted. In all cases, the different parts of any apparatus made of iron should be accurately fitted by boring and grinding, and the above lute is to be applied to the part which is received into an aperture. This will generally be sufficient without any exterior luting; otherwise the lute of clay, sand, and flax, already described, may be used.

In every instance, where a lute or coating is applied, it is advisable to allow it to dry before the distillation is begun; and even the fat lute, by exposure to the air during one or two days after its application, is much improved in its quality. The clay and sand lute is perfectly useless, except it is previously quite dry. In applying a lute, the part immediately over the juncture should swell outwards, and its diameter should be gradually diminished on each side.

Besides the apparatus already described, a variety of vessels and instruments are necessary, having little resemblance to each other in the purposes to which they are adapted. Glass vessels are required for effecting solution, which often requires the application of heat, and sometimes for a considerable duration. In the latter case it is termed digestion, and the vessel called a mattrass is the most proper for performing it. When solution is quickly effected, a bottle, with a rounded bottom, may be used, or a common Florence-oil flask serves the same purpose extremely well, and bears without cracking, sudden changes of temperature. Glass rods, of various length, and spoons of the same material, or of porcelain, are useful for stirring acid and corrosive liquids; and a stock of cylindrical tubes of various sizes, is required for occasional purposes. It is necessary also to be provided with a series of glass measures, graduated into drachms, ounces, and pints.

Accurate beams and scales, of various sizes, with corresponding weights, some of which are capable of weighing several pounds, while the smaller size ascertain a minute fraction of a grain, are essential instruments in the chemical laboratory. So also are mortars of different materials, such as of glass, porcelain, agate, and metal. Wooden stands of various kinds for supporting receivers, should be provided. For purposes of this sort, and for occasionally raising to a proper height any article of apparatus, a series of blocks, made of well-seasoned wood, eight inches (or any other number) square, and respectively eight, four, two, one, and half an inch in thickness, will be found extremely useful; since by combining them in different ways, no less than thirty-one different heights may be attained.

The blowpipe is an instrument of much utility in chemical researches. A small one, invented by Mr. Pepys, with a flat cylindrical box for condensing the vapour of the breath, and for containing caps, to be occasionally applied with apertures of various sizes, is perhaps, the most commodious form. A blowpipe, which is supplied with air from a pair of double bellows, worked by the foot, may be applied to purposes that require both hands to be left at liberty, and will be found useful in blowing glass, and in bending tubes. The latter purpose, however, may be accomplished by holding them over an Argand's lamp with double wicks.

Laboratory, signifies also in military affairs, that place where all sorts of fire-works are prepared both for actual service, and for pleasure, viz. quick matches, fusees, portfires, grape-shot, case-shot, carcases, hand-grenades, cartridges, shells filled and fusees fixed, wads, &c.

LABRUS, a genus of fishes of the order thoracici: the generic character is, teeth strong and subacute: the grinders sometimes, as in the spari, convex and crowded: lips thick and doubled: rays of the dorsal fin, in some species, elongated into soft processes. Gill-covers unarmed and scaly.

Labrus hepatus, snout rather pointed: teeth small: palate furnished with a rough bone. Native of the Mediterranean, sometimes wandering into rivers. There are 41 species belonging to this genus, all of which are but imperfectly understood.

LABOURER. See Master and Servant.

LABYRINTH, in gardening, a winding mazy walk between hedges, through a wood or wilderness. The chief aim is to make the walks so perplexed and intricate, that a person may lose himself in them, and meet with as great a number of disappointments as possible. They are rarely to be met with, except in great gardens; as Versailles, Hampton-court, &c.

LAC, an appellation given to several chemical preparations.

Lac. This resin exudes from the tree called the croton lacciferum, when punctured by an insect. For the history of its formation, and the uses to which it is applied by the insects, the reader is referred to the article Gum, &c. It is a substance of a deep-red colour verging on brown, and semitransparent, and distinguished by various names according to its purity. It possesses the properties of a resin, and is the basis of many varnishes, and of the finest kinds of sealing-wax.

Lac *sulphuris*, is obtained by precipitating sulphur, when in combination: it is composed of sulphur united to a little water.

LACHENALIA, a genus of the class and order hexandria monogynia. The cor. is six-parted, three outer petals difform; caps. three-winged; cells many-seeded; seeds globular, affixed to the recept. There are twelve species, chiefly bulbs of the Cape.

LACTATS, in chemistry, a genus of salts but little known. 1. Lactat of potass, a deliquescent salt soluble in alcohol. 2. Lactat of soda. This salt does not crystallize. It is soluble in alcohol. 3. Lactat of ammonia. Crystals which deliquesce. Heat separates a great part of the ammonia before destroying the acid. 4. Lactat of barytes; lime; alumina; all deliquesce.

LACCIC acid. About the year 1786, Dr. Anderson of Madras mentioned, in a letter to the governor and council of that place, that nests of insects, resembling small cowry shells, had been brought to him from the woods by the natives, who ate them with avidity. These supposed nests he soon afterwards discovered to be the coverings of the females of an undescribed species of coccus, which he shortly found means to propagate with great facility on several of the trees and shrubs growing in his neighbourhood.

On examining this substance, which he called white lac, he observed in it a very considerable resemblance to bees' wax; he noticed also, that the animal which secretes it provides itself by some means or other with a small quantity of honey, resembling that produced by our bees; and in one of his letters he complains, that the children whom he employed to gather it were tempted by its sweetness to eat so much of it, as materially to reduce the produce of his crop. Small quantities of this matter were sent into Europe in 1789, both in its natural state and melted into cakes; and in 1793 Dr. Pearson, at the request of sir Joseph Banks, undertook a chemical examination of its qualities, and his experiments were published in the Philosophical Transactions for 1794.

A piece of white lac, from 3 to 15 grains in weight, is probably produced by each insect. These pieces are of a grey colour, opaque, rough, and roundish. When white lac was purified by being strained through muslin, it was of a brown colour, brittle, hard, and had a bitterish taste. It melted in alcohol, and in water of the temperature of 145°. In many of its properties it resembles bees' wax, though it differs in others; and Dr. Pearson supposes that both substances are composed of the same ingredients, but in different proportions.

1. Two thousand grains of white lac were exposed in such a degree of heat as was just sufficient to melt them. As they grew soft and fluid, there oozed out 550 grains of a reddish watery liquid, which smelled like newly baken bread. To this liquid Dr. Pearson has given the name of laccic acid.

2. It possesses the following properties:

It turns paper stained with turnsole to a red colour.

After being filtred, it has a slightly saltish taste with bitterness, but it is not at all sour.

When heated, it smells precisely like newly baken hot bread.

On standing, it grows somewhat turbid, and deposits a small quantity of sediment.

Its specific gravity at the temperature of 60° is 1.025.

A little of it having been evaporated till it grew very turbid, afforded on standing small needle-shaped crystals in mucilaginous matter.

Two hundred and fifty grains of it were poured into a very small retort and distilled. As the liquor grew warm, mucilage-like clouds appeared; but as the heat increased they disappeared again. At the temperature of 200° the liquor distilled over very fast: a small quantity of extractive matter remained behind. The distilled liquor while hot smelled like newly baken bread, and was perfectly transparent and yellowish. A shred of paper stained with turnsole, which had been put into the receiver, was not reddened; nor did another which had been immersed in a solution of sulphat of iron, and also placed in the receiver, turn to a blue colour upon being moistened with the solution of potass.

About 100 grains of this distilled liquid being evaporated till it grew turbid, after being set by for a night, afforded acicular crystals, which under a lens appeared in a group not unlike the umbel of parsley. The whole of them did not amount to the quarter of a grain. They tasted only bitterish.

Another 100 grains being evaporated to dryness in a very low temperature, a blackish matter was left behind, which did not entirely disappear on heating the spoon containing it very hot in the naked fire; but on heating oxalic acid to a much less degree, it evaporated and left not a trace behind.

Carbonat of lime dissolved in this distilled liquid with effervescence. The solution tasted bitterish, did not turn paper stained with turnsole red, and on adding to it carbonat of potass a copious precipitation ensued. A little of this solution of lime and of alkali being evaporated to dryness, and the residuum made red-hot, nothing remained but carbonat of lime, and carbonat of potass.

This liquid did not render nitrat of lime turbid, but it produced turbidness in nitrat and muriat of barytes.

To 500 grains of the reddish-coloured liquor obtained by melting white lac, carbonat of soda was added till the effervescence ceased, and the mixture was neutralized; for which purpose three grains of the carbonat were necessary. During this combination a quantity of mucilaginous matter, with a little carbonat of lime, was precipitated. The saturated solution being filtrated and evaporated to the due degree, afforded on standing deliquescent crystals, which on exposure to fire, left only a residuum of carbonat of soda.

Lime-water being added to this reddish-coloured liquor produced a light purple turbid appearance; and on standing there were clouds just perceptible.

Sulphuret of lime occasioned a white precipitation, but no sulphureted hydrogen gas was perceptible by the smell.

Tincture of galls produced a green precipitation.

Sulphat of iron produced a purplish colour, but no precipitation; nor was any precipitate formed by the addition first of a little vinegar and then of a little potass to the mixture.

Acetat of lead occasioned a reddish precipitation, which redissolved on adding a little nitric acid.

Nitrat of mercury produced a whitish turbid liquor.

Oxalic acid produced immediately the precipitation of white acicular crystals owing probably to the presence of a little lime in the liquid.

Tartrat of potass produced a precipitation not unlike what takes place on adding tartaric acid to tartrat of potass; but it did not dissolve again on adding potass.

LACE, in commerce, a work composed of many threads of gold, silver, or silk, interwoven one with the other, and worked upon a pillow with spindles, according to the pattern designed; the open work being formed with pins, which are placed and displaced as the spindles are moved.

Method of cleaning gold-lace and embroidery when tarnished.—For this purpose alkaline liquors are by no means to be used; for while they clean the gold they corrode the silk, and change or discharge its colour. Soap also alters the shade, and even the species of certain colours. But spirit of wine may be used without any danger of its injuring either the colour or quality of the subject; and in many cases proves as effectual for restoring the lustre of the gold as the corrosive detergents.

But though spirit of wine is the most innocent material that can be employed for this purpose, it is not in all cases proper. The golden covering may be in some parts worn off; or the base metal, with which it has been iniquitously alloyed, may be corroded by the air, so as to leave the particles of the gold disunited; while the silver underneath, tarnished to a yellow hue, may continue a tolerable colour to the whole: in which cases it is apparent that the removal of the tarnish would be prejudicial to the colour, and make the lace or embroidery less like gold than it was before.

LACE, *bone*, a lace made of fine linen thread or silk, much in the same manner as that of gold and silver. The pattern of the lace is fixed upon a large round pillow, and pins being stuck into the holes or openings in the pattern, the threads are interwoven by means of a number of bobins, made of bone or ivory, each of which contains a small quantity of fine thread, in such a manner as to make the lace exactly resemble the pattern. There are several towns in England, and particularly in Buckinghamshire, that carry on this manufacture; but vast quantities of the finest laces have been imported from Flanders.

LACERTA, *lizard*, a genus of the amphibia class, and of the order of reptiles: the generic character is, body four-footed, elongated, tailed; without any secondary integument.

This numerous genus may be divided into the following sections, viz.

1. Crocodiles, furnished with very strong scales.

2. Guanas, and other lizards, either with serrated or carinated backs and tails.

3. Cordyles, with denticulated, and sometimes spiny scales, either on the body or tail, or both.

4. Lizards proper, smooth, and the greater number furnished with broad square scales or plates on the abdomen.

5. Chamæleons, with granulated skin, large head, long missile tongue, and cylindric tail.

6. Geckos, with granulated or tuberculated skin, and lobated feet, with the toes lamellated beneath.

7. Scinks, with smooth, fish-like, scales.

8. Salamanders, newts, or efts, with soft skins, and of which some are water-lizards.

9. Snake-lizards, with extremely long bodies, very short legs, and minute feet.

The above divisions neither are, nor can be, perfectly precise; since species may occur which may, with almost equal propriety, be referred to either of the neighbouring sections; but, in general, they will be found useful in the investigation of the species. The following are the most noted:

1. Lacerta crocodilus, or crocodile. The crocodile, so remarkable for its size and powers of destruction, has in all ages been regarded as one of the most formidable animals of the warmer regions. It is a native of Asia and Africa, but seems to be most common in the latter; inhabiting large rivers, as the Nile (see Plate Nat. Hist. fig. 237), the Niger, &c. and preying principally on fish, but occasionally seizing on almost every animal which happens to be exposed to its rapacity. The size to which the crocodile sometimes arrives is prodigious; specimens being frequently seen of 20 feet in length, and instances are commemorated of some which have exceeded the length of 30 feet. The armour with which the upper part of the body is covered may be numbered among the most elaborate pieces of nature's mechanism. In the full-grown animal it is so strong and thick as easily to repel a musket-ball; on the lower parts it is much thinner, and of a more pliable nature: the whole animal appears as if covered with the most regular and curious carved work: the colour of a full-grown crocodile is blackish-brown above, and yellowish-white beneath; the upper parts of the legs and the sides varied with deep yellow, and in some parts tinged with green. In the younger animals the colour on the upper parts is a mixture of brown and pale yellow, the under parts being nearly white: the eyes are provided with a nictitating membrane, or transparent moveable pellicle, as in birds: the mouth is of vast width, the rictus or gape having a somewhat flexuous outline, and both jaws being furnished with very numerous sharp-pointed teeth, of which those about the middle part of each jaw considerably exceed the rest in size, and seem analogous to the canine teeth in the viviparous quadrupeds or mammalia: the number of teeth in each jaw is 30, or more; and they are so disposed as to alternate with each other when the mouth is closed: on taking out the teeth and examining the alveoli, it has been found that small teeth were forming beneath, in order to supply the loss of the others when shed: the auditory foramina are situated on the top of the head, above the eyes, and are moderately large, oval, covered by a membrane, having a longitudinal slit or opening, and thus in some degree resembling a pair of closed eyes: the legs are short, but strong and muscular: the fore feet have five toes, and are unwebbed: the hind feet have only four toes, which are united towards their base by a strong web: the two interior toes on each of the fore feet, and the interior one of the hind feet, are destitute of claws: on the other toes are strong, short, and curved claws: the tail is very long, of a laterally compressed form, and furnished above with an upright process, formed by the gradual approximation of two elevated crests proceeding from the lower part of the back.

The crocodile in a young state is by no means to be dreaded, its small size and weakness preventing it from being able to injure any of the larger animals: it therefore contents itself with fish and other small prey; and such as have occasionally been brought to Europe are so far from being formidable or ferocious, that they may be generally handled with impunity, and either from weakness, or the effect of a cold climate, seem much inclined to torpidity; but in the glowing regions of Africa, where it arrives at its full strength and power, it is justly regarded as the most formidable inhabitant of the rivers. It lies in wait near the banks, and snatches dogs and other animals, swallowing them instantly, and then plunging into the flood, and seeking some retired part, where it may lie concealed till hunger again invites it to its prey. In its manner of attack it is exactly imitated by the common lacerta palustris, or water-newt, which, though not more than four or five inches long, will with the greatest ease swallow an insect of more than an inch in length; and that at one single effort, and with a motion so quick, that the eye can scarcely follow it. It poises itself in the water, and having gained a convenient distance, springs with the utmost celerity on the insect, and swallows it. If, therefore, a small lizard of four or five inches only in length can thus instantaneously swallow an animal of a fourth part of its own length, we need not wonder that a crocodile of 18, 20, or 25, feet long, should suddenly ingorge a dog or other quadruped.

Crocodiles, like the rest of the lacertæ, are oviparous: they deposit their eggs in the sand or mud near or on the banks of the rivers they frequent, and the young when hatched immediately proceed to the water; but the major part are said to be commonly devoured by other animals, as ichneumons, birds, &c. The egg of the common nilotic crocodile is not much larger than that of a goose, and in external appearance bears a most perfect resemblance to that of a bird; being covered with a calcareous shell, under which is a membrane. When the young are first excluded the head bears a much larger proportion to the body than when full-grown. The eggs, as well as the flesh of the crocodile itself, are numbered among the delicacies of some of the African nations, and are said to form one of their favourite repasts.

In the large rivers of Africa crocodiles are said to be sometimes seen swimming together in vast shoals, and resembling the trunks of so many large trees floating on the water.

The negroes will sometimes attack and kill a single crocodile, by stabbing it under the belly, where the skin, at the interstices of the scales, is soft and flexible. It is also, in some countries, the custom to hunt the crocodile by means of strong dogs, properly trained to the purpose, and armed with spiked collars. It is likewise pretended, that in some parts of Africa crocodiles are occasionally tamed; and it is said that they form an article of royal magnificence with the monarchs of those regions, being kept in large ponds or lakes appropriated to their residence. We may add, that the antient Romans exhibited these animals in their public spectacles and triumphs. Scaurus, during his ædileship, treated the people with a sight of five crocodiles, exhibited in a temporary lake; and Augustus introduced one into his triumph over Cleopatra, as well as several others, for the entertainment of the people.

2. Lacerta alligator. So very great is the general resemblance between this animal and the crocodile, that many naturalists have been strongly inclined to consider it as a mere variety, rather than a distinct species. The more accurate discrimination, however, of Blumenbach and some others seems in reality to prove that the alligator or American crocodile is specifically distinct from the nilotic, though the difference is not such as immediately to strike a general observer. The leading difference, if it be allowed to constitute a distinction of species, seems to be, that the head of the alligator is rather smooth on the upper part than marked with those very strong rugosities and hard carinated scales which appear on that of the crocodile; and that the snout is considerably flatter and wider, as well as more rounded at the extremity. The alligator arrives at a size not much inferior to that of the crocodile, specimens having been often seen of 18 or 20 feet in length.

"Though the largest and greatest numbers of alligators," says Catesby, "inhabit the torrid zone, the continent abounds with them 10 degrees more north, particularly as far as the river Neus in North Carolina, in the latitude of about 33 degrees, beyond which I have never heard of any, which latitude nearly answers to the northernmost parts of Africa, where they are likewise found. They frequent not only salt rivers near the sea, but streams of fresh water in the upper parts of the country, and in lakes of salt and fresh water, on the banks of which they lie lurking among reeds, to surprise cattle and other animals. In Jamaica, and many parts of the continent, they are found about 20 feet in length: they cannot be more terrible in their aspect than they are formidable and mischievous in their natures, sparing neither man nor beast they can surprise, pulling them down under water, that being dead, they may with greater facility, and without struggle or resistance, devour them. As quadrupeds do not so often come in their way, they almost subsist on fish; but as Providence, for the preservation, or to prevent the extinction of defenceless creatures, has in many instances restrained the devouring appetites of voracious animals, by some impediment or other, so this destructive monster, by the close connexion of his vertebræ, can neither swim nor run any other way than straight forward, and is consequently disabled from turning with that agility requisite to catch his prey by pursuit: therefore they do it by surprise in the water as well as by land; for effecting which nature seems in some measure to have recompensed their want of agility, by giving them a power of deceiving and catching their prey by a sagacity peculiar to them, as well as by the outer form and colour of their body, which on land resembles an old dirty log or tree, and in the water frequently lies floating on the surface, and there has the like appearance, by which, and his silent artifice, fish, fowl, turtle, and all other animals, are deceived, suddenly catched, and devoured.

"In Carolina they lie torpid from about October to March, in caverns and hollows in the banks of rivers, and at their coming out in the spring make an hideous bellowing noise. The hind part of their belly and tail are eaten by the Indians. The flesh is delicately white, but has so perfumed a taste and smell that I never could relish it with pleasure."

3. Lacerta gangetica. The gangetic crocodile is so strikingly distinguished both from the nilotic and the alligator by the peculiar form of the mouth, that it is hardly possible, even on a cursory view, to confound it with either of the former; the jaws being remarkably long, narrow, and perfectly straight, and the upper mandible terminated above an elevated tubercle. In a very young state the length and narrowness of the snout are still more conspicuous than in the full-grown animal. The teeth are nearly double the number of those of the common crocodile, and are of equal size throughout the whole length of the jaws. This species is a native of India, and is principally seen in the Ganges, where it arrives at a size at least equal to the nilotic crocodile.

4. Lacerta iguana. Though the lizard tribe affords numerous examples of strange and peculiar form, yet few species are perhaps more eminent in this respect than the guana, which grows to a very considerable size, and is often seen of the length of three, four, and even five feet. It is a native of many parts of America and the West Indian islands, and is also said to occur in some parts of the East Indies. Its general colour is green, but with much variation in the tinge of different individuals: it is generally shaded with brown in some parts of the body, and sometimes this is even the predominating colour. The back of the guana is very strongly serrated; and this, together with the gular pouch, which it has the power of extending or inflating occasionally to a great degree, gives a formidable appearance to an animal otherwise harmless. It inhabits rocky and woody places, and feeds on insects and vegetables. It is itself reckoned an excellent food, being extremely nourishing and delicate; but it is observed to disagree with some constitutions. The common method of catching it is by casting a noose over its head, and thus drawing it from its situation; for it seldom makes an effort to escape, but stands looking intently at its discoverer, inflating its throat at the same time in an extraordinary manner.

The guana may be easily tamed while young, and is both an innocent and beautiful creature in that state.

5. Lacerta basiliscus. The basilisk of the antients, supposed to be the most malignant of all poisonous animals, and of which the very aspect was said to be fatal, is a fabulous existence, to be found only in the representations of painters and poets.

But the animal known in modern natural history by this name is a species of lizard, of a very singular shape, and which is particularly distinguished by a long and broad wing-like process or expansion continued along the whole length of the back, and to a very considerable distance on the upper part of the tail, and furnished at certain distances with internal radii analogous to those in the fins of fishes, and still more so to those in the wings of the draco volans, or flying lizard. This process is of different elevation in different parts, so as to appear strongly sinuated and indented, and is capable of being either dilated or contracted at the pleasure of the animal. The occiput or hind part of the head is elevated into a very conspicuous pointed hood or hollow crest.

Notwithstanding its formidable appearance the basilisk is a perfectly harmless animal, and, like many other of the lizard tribe, resides principally among trees, where it feeds on insects, &c. The colour of the basilisk is a pale cinereous brown, with some darker variegations towards the upper part of the body. It is principally found in South America, and sometimes considerably exceeds the length before mentioned, measuring three feet, or even more, from the nose to the extremity of the tail. It is said to be an animal of great agility, and is capable of swimming occasionally with perfect ease, as well as of springing from tree to tree by the help of its dorsal crest, which it expands in order to support its flight.

6. Lacerta calotes. This species is considerably allied to the common guana in habit or general appearance; but is of much smaller size, rarely exceeding the length of a foot and a half from the tip of the nose to the extremity of the tail. It is also destitute of the very large gular pouch, so conspicuous in that animal; instead of which it has merely a slight inflation or enlargement on that part. In colour it occasionally varies, like most of this tribe; but it is commonly of an elegant bright blue, variegated by several broad, and somewhat irregular white or whitish transverse bands on each side of the body and tail. It is a native of the warmer regions both of Asia and Africa, and is found in many of the Indian islands, and particularly in Ceylon, in which it is common. According to the count de Cepede it is also found in Spain, &c. and is said by that author to wander about the tops of houses in quest of spiders; and he observes, that it is even reported to prey on rats, and to fight with small serpents in the manner of the common green lizard and some others. See Plate Nat. Hist. fig. 236.

7. Lacerta monitor. The monitor, or monitory lizard, is one of the most beautiful of the whole tribe, and is also one of the largest; sometimes measuring not less than four or five feet from the nose to the tip of the tail. Its shape is slender and elegant, the head being small, the snout gradually tapering, the limbs moderately slender, the tail laterally compressed, and insensibly decreasing towards the tip, which is very slender and sharp. Though the colours of this lizard are

simple, yet such is their disposition, that it is impossible to survey their general effect without admiration. In this respect, however, the animal varies perhaps more than most others of its tribe. It is commonly black, with the abdomen white, the latter colour extending to some distance up the sides, in the form of several pointed bands, besides which the whole body is generally ornamented by several transverse bands consisting of white annular spots, while the head is marked with various streaks of the same colour, the limbs with very numerous round spots, and the tail with broad, distant, transverse bands. It is a native of South America, where it frequents woody and watery places; and, if credit may be given to the reports of some authors, is of a disposition as gentle as its appearance is beautiful. It has even gained the title of monitor, salvaguarda, &c. from its pretended attachment to the human race, and it has been said that it warns mankind of the approach of the alligator by a loud and shrill whistle.

Cordyles, with either denticulated or spiny scales on the body or tail, or both.

8. Lacerta pelluma, is one of the middle-sized lizards; the total length being nearly two feet, and the length of the body and tail nearly equal. It is a native of Chili, where it is said to inhabit hollows under ground. It is covered on the upper parts with very minute scales, and is beautifully variegated with green, yellow, blue, and black: the under parts are of a glossy yellowish-green: the tail long and verticillated by rows of rhomboid scales. The skin of this lizard is said to be used by the Chilians for the purpose of a purse.

9. Lacerta stellio, is remarkable for the unusually rough or hispid appearance of its whole upper surface; both body, limbs, and tail, being covered with pointed scales, projecting here and there to a considerable distance beyond the surface, so that it appears muricated with spines: the tail is rather short than long, and is verticillated with rows of pointed scales. The general colour of the animal is a pale blueish-brown, with a few deeper and lighter transverse variegations: its general length is about eight inches. It is a native of many parts of Africa.

Lizards proper, smooth, and the greater number furnished with broad square plates or scales on the abdomen.

10. Lacerta agilis, green lizard, is found in all the warmer parts of Europe, and seems pretty generally diffused over the antient continent. It sometimes arrives at a very considerable size, measuring more than two feet to the extremity of the tail: its more general length, however, is from 10 to 15 inches. In its colours it is the most beautiful of all the European lacertæ, exhibiting a rich and varied mixture of darker and lighter green, interspersed with specks and marks of yellow, brown, blackish, and even sometimes red. The green lizard is found in various situations, in gardens, about warm walls, buildings, &c. and is an extremely active animal, pursuing with great celerity its insect prey, and escaping with great readiness from pursuit when disturbed. If taken, however, it is soon observed to become familiar, and may even be tamed to a certain degree; for which reason it is considered as a favourite animal in many of the warmer parts of Europe. It appears to run into numerous varieties both as to size and colour; but in all these states the particular characteristics of the species are easily ascertained.

11. Lacerta bullaris, red-throat lizard. This, according to Catesby, is usually six inches long, and of a shining grass-green colour. It is common in Jamaica, frequenting hedges and trees, but is not seen in houses: when approached it swells its throat into a globular form, the protruded skin on that part appearing of a bright-red colour, which disappears in its withdrawn or contracted state: this action is supposed to be a kind of menace, in order to deter its enemy; but it is incapable of doing any mischief by its bite or otherwise. See Plate Nat. Hist. fig. 235.

Chameleons, with granulated skin, missile tongue, &c.

12. Lacerta chamæleon. Few animals have been more celebrated by natural historians than the chameleon, which has been sometimes said to possess the power of changing its colour at pleasure, and of assimilating it to that of any particular object or situation. This, however, must be received with very great limitations; the change of colour which the animal exhibits varying in degree according to circumstances of health, temperature of the weather, and many other causes, and consisting chiefly in a sort of alteration of shades from the natural greenish or blueish grey of the skin into pale yellowish, with irregular spots or patches of dull red.

It is also to be observed, that the natural or usual colour of chameleons varies very considerably; some being much darker than others, and it has even been seen approaching to a blackish tinge. An occasional change of colour is likewise observable, though in a less striking degree, in some other lizards.

The general length of the chameleon, from the tip of the nose to the beginning of the tail, is about ten inches, and the tail is of nearly similar length, but the animal is found of various sizes, and sometimes exceeds the length above mentioned. It is a creature of a harmless nature, and supports itself by feeding on insects; for which purpose the structure of the tongue is finely adapted, consisting of a long, missile body, furnished with a dilated and somewhat tubular tip, by means of which the animal seizes insects with great ease, darting out its tongue in the manner of a woodpecker, and retracting it instantaneously with the prey secured on its tip. It can also support a long abstinence, and hence arose the popular idea of the chameleon being nourished by air alone. It is found in many parts of the world, and particularly in India and Africa. It is also sometimes seen in the warmer parts of Spain and Portugal.

The general or usual changes of colour in the chameleon, are from a blueish ash-colour, (its natural tinge) to a green and sometimes yellowish colour, spotted unequally with red. If the animal is exposed to a full sunshine, the unilluminated side generally appears, within the space of some minutes, of a pale yellow, with large roundish patches or spots of red-brown. On reversing the situation of the animal, the same change takes place in an opposite direction; the side which was before in the shade now becoming either brown or ash-colour, while the other side becomes yellow and red; but these changes are subject to much variety both as to intensity of colours and disposition of spots.

Besides the common chameleon, different races appear to exist, which are principally distinguished by their colour, and the more or less elevated state of the angular or crested part of the head. These, which Linnæus was content to consider as varieties, are now raised to the dignity of species, and are so distinguished in the Gmelinian edition of the Systema Naturæ.

Geckos, with granulated or tuberculated skin, lobated feet, and toes lamellated beneath.

13. Lacerta gecko. The gecko, said to be so named from the sound of its voice, which resembles the above word uttered in a shrill tone, is a native of many parts of Asia and Africa, as well as of some of the warmer regions of Europe. It is one of the middle-sized lizards, measuring, in general, about a foot in length, or rather more. It is of a thicker and stouter form than most other lizards, having a large and somewhat triangular flattish head, covered with small scales, a wide mouth, large eyes, minute teeth, and a broad flat tongue. The limbs are of moderate length, and the feet are of a broader form than the rest of the genus.

The gecko inhabits obscure recesses, caverns, old walls, trees, &c. and wanders about chiefly on the approach of rain. It is considered as of a poisonous nature, a highly acrimonious kind of fluid exuding from the lamellæ of the feet, which remaining on the surface of fruit or any other edible substance is often productive of troublesome symptoms to those who happen to swallow it. From the peculiar structure of its feet, the gecko can readily adhere to the smoothest surfaces. The general colour of the animal is pale brown, with a few irregular dusky or blueish variegations; but in those which inhabit the warmer regions of the globe, this colour seems to be exalted into a much more brilliant appearance.

14. Lacerta fimbriata. This remarkable species seems to have been first described by the count de Cepede, who informs us that it appears in some degree to connect the chameleon, the gecko, and the water-newts; the head, skin, and general form of the body, resembling those of the chameleon: the tail that of the water-newts, being of a compressed form, though in a different manner (not vertically but horizontally flattened), while the feet resemble those of the gecko. The largest specimen examined by the count de Cepede measured about eight inches and six lines in length, of which the tail measured two inches and four lines.

The colour of this animal is not constant or permanent, as in most lizards, but variable, as in the chameleon, presenting successively different shades of red, yellow, green, and blue. This variation of colour is, however, confined to the upper surface of the animal; the lower always continuing of a bright yellow. These changes, we are informed, have been observed in the living animal by Mons. Bruyeres, in his native country, viz. Madagascar, where it is not very uncommon, and where, though a harmless animal, it is held in great abhorrence by the natives, who consider it as of a poisonous nature, and fly from it with precipitation; pretending that it darts on their breast, and adheres with such force by its fringed membrane, that it cannot be separated from the skin without the assistance of a razor. The principal cause of this popular dread of the animal, is its habit of running open-mouthed towards the spectator, instead of attempting to escape when discovered. Its chief residence is on the branches of trees, where it lives on insects, holding itself secure by coiling its tail, short as it is, half round the twig on which it sits. It chiefly appears in rainy weather, when it moves with considerable agility, often springing from bough to bough. On the ground it walks but slowly, the fore legs being shorter than the hinder.

Scinks, with round fish-like scales.

15. Lacerta scincus, or officinal scink. The scink is one of the middle-sized or smaller lizards, and is a native of many of the eastern parts of the world. It abounds in Lybia, Syria, Egypt, and Arabia, frequenting moderately dry and sandy soils, and growing to the length of six or seven inches, or even sometimes more. The head of the scink is rather small than large, the body thick and round, the tail in general considerably shorter than the body. The whole animal is of a pale yellowish-brown colour, with a few broad, dusky, transverse undulations or zones, and is uniformly covered with moderately large or fish-like scales, lying extremely close and smooth, so that the surface has a glossy or oily appearance. It is an animal of harmless manners, and, like most other lizards, supports itself on the various insects which wander about the regions it inhabits.

This animal was once in high estimation as an article in the materia medica, and the flesh, particularly of the belly, was supposed to be diuretic, alexipharmic, restorative, and useful in leprous and many other cases; but whatever virtues it may possess when used fresh, it is not considered as of any importance when in its dried or imported state, and while it continued to be used in practice served only to increase the number of ingredients in that curious remnant of what Dr. Lewis happily terms the wild exuberance of medical superstition in former ages, the celebrated confectio damocratis, or mithridate.

Salamanders, Newts, or Efts.

16. Lacerta salamandra. The salamander, so long the subject of popular error, and of which so many idle tales have been recited by the more antient naturalists, is an inhabitant of many parts of Germany, Italy, France, &c. but does not appear to have been discovered in England. It delights in moist and shady places, woods, &c. and is chiefly seen during a rainy season. In the winter it lies concealed in the hollows about the roots of old trees, in subterraneous recesses, or in the cavities of old walls, &c. The salamander is easily distinguished by its colours; being of a deep shining black, variegated with large, oblong, and rather irregular patches of bright orange-yellow, which, on each side of the back, are commonly so disposed as to form a pair of interrupted longitudinal stripes: the sides are marked by many large transverse wrinkles, the intermediate spaces rising into strongly marked convexities; and the sides of the tail often exhibit a similar appearance: on each side of the back of the head are situated a pair of large tubercles, which are in reality the parotid glands: and are thus protuberant not only in some others of the lizard tribe, but in a remarkable manner in the genus rana: these parts, as well as the back and sides of the body, are beset in the salamander with several large open pores or foramina, through which exudes a peculiar fluid, serving to lubricate the skin, and which, on any irritation, is secreted in a more sudden and copious manner under the form of a whitish gluten, of a slightly acrimonious nature; and from the readiness with which the animal, when disturbed, appears to evacuate it, and that even occasionally to some distance, has arisen the long-continued popular error of the salamander's being enabled to live uninjured in the fire, which it has been supposed capable of extinguishing by its natural coldness and moisture: the real fact is, that like any of the cold and glutinous animals, as snails, &c. it, of course, is not quite so instantaneously destroyed by the force of fire as an animal of a drier nature would be. The general length of the salamander is about seven or eight inches, though it sometimes arrives at a much larger size. It is capable of living in water as well as on land, and is sometimes found in stagnant pools, &c. Its general pace is slow, and its manners torpid.

A strange error appears to have prevailed relative to the supposed poisonous nature of this animal; and the malignity of its venom has even been considered as scarcely admitting a remedy. It may be sufficient to observe, that the salamander is perfectly innoxious, and incapable of inflicting either wound or poison on any of the larger animals, though it appears, from the experiments of Laurenti, that the common small grey lizard (L. agil. var.) is poisoned by biting a salamander, and thus swallowing the secreted fluid of the skin; becoming almost immediately convulsed, and dying in a very short time afterwards.

The salamander is a viviparous species; producing its young perfectly formed, having been first hatched from internal eggs, as in the viper, and some other amphibia. It is said to retire to the water in order to deposit its young, which, at the first exclusion, are furnished with ramified branchial fins or processes on each side the neck, and which being merely temporary organs, are afterwards obliterated, as in the young of frogs and water-newts. The number of young produced at one birth by the salamander is said sometimes to amount to 30 or 40.

17. Lacerta vulgaris. This, which is the smallest of the British lizards, is altogether a terrestrial species. It is commonly seen in gardens, and not unfrequently in the neighbourhood of dunghills, &c. It also occasionally makes its way into cellars in the manner of the slug, the toad, &c.

18. Lacerta aquatica. This, which in England occurs almost in every stagnant water, is a small species. Its general length is about three inches and a half, and it very rarely exceeds that of four inches at most.

The water-newts are remarkable for a high degree of reproductive power, and have been known to exhibit the restoration of their legs, tails, and even, according to Dr. Blumenbach, of the eyes themselves, after having been deprived of them by cutting.

Snake lizards, with extremely long bodies and short legs.

19. Lacerta chalcides. The chalcides is a native of many of the warmer parts of Europe, as well as of Africa, and is found of different sizes, from the length of a few inches to that of a foot, or even more. Its general length, however, seems to be eight or nine inches. The chalcides is an animal of a harmless nature, frequenting moist shady places, moving rather slowly, and feeding on insects, small worms, &c. It is a viviparous species, and is said to produce a great many young. The serpents to which it bears the nearest alliance in point of form, are those of the genus anguis, and particularly the A. fragilis, or common slow-worm.

20. Lacerta apus. A still nearer approach is made to the snake tribe by this large and singular lizard than even by the chalcides. It is a native of Greece, the southern parts of Siberia, and doubtless of many other parts of Europe and Asia, though it seems to have been but recently known to naturalists. It is found of the length of nearly three feet, and so perfectly resembles the general form of a large snake, that it is not without a near inspection that it is ascertained to belong to the race of lizards; being furnished merely with a pair of very short and somewhat acuminated processes by way of feet, situated at a vast distance from the fore parts of the body, nearly on each side the vent: the processes have no divisions or toes, but seem to form one simple projection, with a slight indenture only. The animal frequents moist and shady places, and appears to be of a harmless character.

LACHNEA, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking under the 31st order, vepreculæ. There is no calyx; the corolla is quadrifid, with the limb unequal; there is one seed a little resembling a berry. There are two species, shrubs of the Cape.

LACHRYMALIS, FISTULA. See SURGERY.

LACHRYMATORY, in antiquity, a vessel wherein were collected the tears of a deceased person's friends, and preserved along with the ashes and urn.

LACIS, a genus of the class and order polyandria digynia. There is no calyx or corolla. The filaments are winged on both sides below; the receptacle is girt with 12 spines; capsules ovate. There is one species, an aquatic of Guiana.

LACISTEMA, a genus of the monandria digynia class and order. The calyx is the scale of the ament; corolla four-parted; filaments bifid; berry pedicelled, one-seeded. There is one species, a shrub of Jamaica.

LACK OF RUPEES, is 100,000 rupees; which, supposing them standard, or siccas, at 2*s.* 6*d.* amounts to 12,500*l.* sterling.

LACQUERS, are varnishes applied upon tin, brass, and other metals, to preserve them from tarnishing, and to improve their colour. The basis of lacquers is a solution of the resinous substance called seed-lac in spirit of wine. The spirit ought to be very much concentrated, in order to dissolve much of the lac. For this purpose, some authors direct dry potass to be thrown into the spirit. This alkali attracts the water, with which it forms a liquid that subsides distinctly from the spirit at the bottom of the vessel. From this liquid the spirit may be separated by decantation. By this method the spirit is much concentrated; but, at the same time, it becomes impregnated with part of the alkali, which depraves its colour, and communicates a property to the lacquer of imbibing moisture from the air. These inconveniences may be prevented by distilling the spirit; or, if the artist has not an opportunity of performing that process, he may cleanse the spirit, in a great measure, from the alkali, by adding to it some calcined alum; the acid of which uniting with the alkali remaining in the spirit, forms with it a vitriolated tartar, which, not being soluble in spirit of wine, falls to the bottom together with the earth of the decomposed alum. To a pint of the purified spirit, about three ounces of powdered shell-lac are to be added; and the mixture to be digested during the same day with a moderate heat. The liquor ought then to be poured off, strained, and cleared by settling. This clear liquor is now fit to receive the required colour from certain resinous colouring substances, the principal of which are gamboge and annotto; the former of which gives a yellow, and the latter an orange colour. In order to give a golden colour, two parts of gamboge are added to one of annotto; but these colouring substances may be separately dissolved in the tincture of lac, and the colour required may be adjusted by mixing the two solutions in different proportions. When silver leaf or tin is to be lacquered, a larger quantity of the colouring materials is requisite than when the lacquer is intended to be laid on brass.

LACTEAL VESSELS. See ANATOMY.

LACTIC ACID. If milk be kept for some time it becomes sour. The acid which then appears in it was first examined by Scheele, and found by him to have peculiar properties. It is called lactic acid. In the whey of milk this acid is mixed with a little curd, some phosphat of lime, sugar of milk, and mucilage. All these must be separated before the acid can be examined. Scheele accomplished this by the following process:

Evaporate a quantity of sour whey to an eighth part, and then filtrate it: this separates the cheesy parts. Saturate the liquid with lime-water, and the phosphat of lime precipitates. Filtrate again, and dilute the liquid with three times its own bulk of water; then let fall into it oxalic acid, drop by drop, to precipitate the lime which it has dissolved from the lime-water; then add a very small quantity of lime-water, to see whether too much oxalic acid has been added. If there has, oxalat of lime immediately precipitates. Evaporate the solution to the consistence of honey, pour in a sufficient quantity of alcohohol, and filtrate again; the acid passes through dissolved in the alcohol, but the sugar of milk and every other substance remain behind. Add to the solution a small quantity of water, and distil with a small heat, the alcohol passes over, and leaves behind the lactic acid dissolved in water.

This acid is incapable of crystallizing: when evaporated to dryness, it deliquesces again in the air. When distilled, water comes over first, then a weak acid resembling the tartaric, then an empyreumatic oil mixed with more of the same acid, and, lastly, carbonic acid and carbureted hydrogen gas: there remains behind a small quantity of charcoal.

The combinations which this acid forms with alkalies, earths, and metallic oxides, are called lactats, which see.

All that is known concerning these salts are the following facts, ascertained by Scheele. When saturated with fixed alkalies, it gave salts which were deliquescent and soluble in spirit of wine. It formed deliquescent salts with ammonia, with barytes, with lime, and alumina; but with magnesia it formed small crystals, which however at length deliquesced. This acid had no effect on bismuth, cobalt, antimony, tin, mercury, silver, and gold. It dissolved zinc and iron; and it produced with these metals hydrogen gas. Zinc was the only metal with which it crystallized. Copper rendered this acid first slightly blue, then green, and lastly a deep blue; but no crystals were formed. Digested upon lead it became sweet, but did not crystallize.

LACTUCA, the *lettuce*, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the calyx imbricated, cylindrical, with a membranaceous margin; the pappus is simple, stipated, or stalked. There are 11 species, most of which are plants of no use, and never cultivated but in botanic gardens for variety. That commonly cultivated in the kitchen-garden is the sative, which includes the following varieties: 1. The common or garden lettuce. 2. Cabbage lettuce. 3. Silesia lettuce. 4. Dutch brown lettuce. 5. Aleppo, or sperm lettuce. 6. Imperial lettuce. 7. Green capuchin lettuce. 8. Versailles, or upright white cos lettuce. 9. Black cos. 10. Red cos. 11. Red capuchin lettuce. 12. Roman lettuce. 13. Prince lettuce. 14. Royal lettuce. 15. Egyptian cos lettuce.

The first of these sorts is very common in all gardens, and is commonly sown for cutting very young, to mix with other salad herbs in spring; and the second, or cabbage lettuce, is only this mended by culture. The first crop should be sown in February, in an open situation; the others at three weeks distance; but the later ones under covert, but not under the drippings of trees. The Silesia, imperial, royal, black, white, and upright cos lettuces, may be first sown in the latter part of February or the beginning of March, on a warm light soil, and in an open situation: when the plants are come up, they must be thinned to 15 inches distance every way; they will then require no further care than the keeping them clear of weeds; and the black cos, as it grows large, should have its leaves tied together to whiten the inner part. Succeeding crops of these should be sown in April, May, and June; and towards the latter part of August they may be sown for a winter crop, to be preserved under glasses, or in a bed arched over with hoops and covered with mats. The most valuable of all the English lettuces are the white cos, or the Versailles; the Silesia; and the Egyptian cos. The brown Dutch and the green capuchin are very hardy, and may be sown late under walls, where they will stand the winter, and be valuable when no others are to be had. The red capuchin, Roman, and prince lettuce, are very early kinds, and are sown for variety; as are also the Aleppo ones for the beauty of their spotted leaves.

The several sorts of garden lettuces are very wholesome, emollient, cooling salad herbs, easy of digestion, and somewhat loosening the belly. Most writers suppose that they have a narcotic quality; and indeed in many cases they contribute to procure rest: this they effect by abating heat, and relaxing the fibres. The seeds are in the number of the four lesser cold seeds.

LACUNAR. See ARCHITECTURE.

LADDERS, *scaling*, in the military art, are used in scaling when a place is to be taken by surprise. They are made several ways: here we make them of flat staves, so that they may move about their pins, and shut like a parallel ruler, for conveniently carrying them: the French make them of several pieces, so as to be joined together, and to be made of any necessary length: sometimes they are made of single ropes, knotted at proper distances, with iron hooks at each end, one to fasten them upon the wall above, and the other in the ground; and sometimes they are made with two ropes, and staves between them, to keep the ropes at a proper distance, and to tread upon. When they are used in the action of scaling walls, they ought to be rather too long than too short, and to be given in charge only to the stoutest of the detachment. The soldiers should carry these ladders with the left-arm passed through the second step, taking care to hold them upright close to their sides, and very short below, to prevent any accident in leaping into the ditch.

The first rank of each division, provided with ladders, should set out with the rest at the signal, marching resolutely with their firelocks slung, to jump into the ditch: when they are arrived they should apply their ladders against the parapet, observing to place them towards the salient angles rather than the middle of the curtin, because the enemy have less force there. Care must be taken to place the ladders within a foot of each other, and not to give them too much or too little slope, so that they may not be overturned or broken with the weight of the soldiers mounting upon them.

The ladders being applied, those who have carried them, and those who come after, should mount up, and rush upon the enemy sword in hand: if he who goes first happens to be overturned, the next should take care not to be thrown down by his comrade; but, on the contrary, immediately mount himself, so as not to give the enemy time to load his piece.

As the soldiers who mount first may be easily tumbled over, and their fall may cause the attack to fail, it would perhaps be right to protect their breasts with the fore parts of cuirasses; because if they can penetrate the rest may easily follow.

LADY'S SMOCK. See CARDEMINE.

LADY'S SLIPPER. See CYPRIPEDIUM.

LAETIA, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous, or none; the calyx is pentaphyllous; the fruit is unilocular and trigonal; the seeds have a pulpy arillus or coat. There are four species, natives of America. One of them, the apetala, or gum-wood, Dr. Wright informs us, is very common in the woodlands and copses of Jamaica, where it rises to a considerable height and thickness. Pieces of the trunk or branches, suspended in the heat of the sun, discharge a clear turpentine or balsam, which concretes into a white resin, and which seems to be the same as gum sandarach. Pounce is there made of it; and our author is of opinion that it might be useful in medicine like other gums of the same nature.

LAGERSTROEMIA, a genus of the monogynia order, in the polyandria class of plants. The corolla is hexapetalous, and curled; the calyx sexfid, and campanulated; there are many stamina, and of these the six exterior ones thicker than the rest, and longer than the petals. There are four species, trees of the East Indies.

LAGOECIA, a genus of the monogynia order, in the pentandria class of plants. The involucrum is universal and partial; the petals bifid; the seeds solitary, inferior. There is one species, wild cummin, an annual, of the Levant.

LAGUNEA, a genus of the class and order monadelphia polyandria. The calyx is simple, five-cusped; style simple; stigma peltated; capsule five-celled, five-valved. There are three species, shrubs of the East Indies and Surinam.

LAGURUS, a genus of the digynia order, in the triandria class of plants, and in the natural method ranking under the fourth order, gramina. The calyx is bivalved with a villous awn, the exterior petal of the corolla terminated by two awns, with a third on its back retorted. There is one species, a grass of the south of Europe.

LAKES, certain colours made by combining the colouring matter of cochineal, or of certain vegetables, with pure alumine, or with oxide of tin, zinc, &c.

LAMA, the sovereign pontiff, or rather god, of the Asiatic Tartars, inhabiting the country of Barantola. The lama is not only adored by the inhabitants of the country, but also by the kings of Tartary, who send him rich presents, and go in pilgrimage to pay him adoration, calling him lama-congiu, *i. e.* God the everlasting father of heaven. He is never to be seen but in a secret place of his palace, amidst a great number of lamps, sitting cross-legged upon a cushion, and adorned all over with gold and precious stones; where, at a distance, they prostrate themselves before him, it not being lawful for any to kiss even his feet. He is called the great lama, or lama of lamas, that is, priest of priests. And to persuade the people that he is immortal, the inferior priests, when he dies, substitute another in his stead, and so continue to cheat from generation to generation. These priests persuade the people that the lama was raised from death many hundred years ago, that he has lived ever since, and will continue to live for ever.

LAMINÆ, in physiology, the thin plates of which many substances consist.

LAMIUM, *dead-nettle*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. The upper lip of the corolla is entire, arched, the under lip bilobous; the throat with a dent or tooth on each side of the margin. There are 13 species, of which only two, viz. the album, white archangel or dead-nettle, and the purpureum, or red archangel, deserve notice. The flowers of the first, which appear in April and May, have been particularly celebrated in uterine fluors, and other female weaknesses, and also in disorders of the lungs; but they appear to be of very weak virtue. The young leaves of both species are boiled and eaten in some places like greens.

LAMP, a vessel containing oil, with a lighted wick; of which there an indefinite number made of various constructions for various purposes. We shall particularly notice Argand's lamp, and an improvement made upon it.

Argand's lamp is a very ingenious contrivance, and is the invention of a citizen of Geneva. The principle on which the superiority of the lamp depends, is the admission of a larger quantity of air to the flame than can be done in the common way. This is accomplished by making the wick of a circular form, by which means a current of air rushes through the cylinder on which it is placed, with great force; and, along with that which has access to the outside, excites the flame to such a degree that the smoke is entirely consumed. Thus both the light and heat are prodigiously increased, at the same time that there is a very considerable saving in the expence of oil, the consumption of the inflammable matter being exceedingly augmented by the quantity of air admitted to the flame; so that what in common lamps is dissipated in smoke is here converted into a brilliant flame.

This lamp is now very much in use, and is consequently well known.

We shall now describe an improvement of this neat invention. See Plate Lamp, &c.

The upper compartment of the Plate represents an improved construction of Argand's lamp. A, fig. 1, is the reservoir for the oil, which unscrews at B; in order to fill it the oil is poured in at a hole *a*, fig. 4, in the lower end of the reservoir, which is covered, when the lamp is not burning, by a sliding collar, *b*, drawn up by a handle, *d*, which comes through a hole in the screw *e*, by which the reservoir is screwed in the short tube, E, fig. 1: there being no vent-holes in the upper part of the reservoir, A, to admit the air as the oil runs out, a bubble of air must enter the hole *a*, fig. 4, to supply the place of every drop of oil that comes out, when the reservoir, A, is screwed to the tube, E; the collar, *b*, being down, the oil runs out (the air being admitted from without through a small hole, *f*), till E is filled above the level of the hole, *a*, which prevents more air getting in; it remains in this state till by the burning of the lamp the oil is drawn down beneath the hole *a*, when it is filled again as before; by this means the lamp is always well supplied, but never overstocked with oil. From the bottom of the tube, E, fig. 1, the oil is conveyed by a pipe, D, to the lamp, the constitution of which is best explained in fig. 2; EF is the external tube of brass, which is supplied with oil by the pipe D; in the centre of this another tube, GG, is soldered, which is open at both ends: between these tubes is a cylinder of slightly wove cotton, *gg*, called the wick; this is fastened to a small cylinder of brass, *hh* (shewn separately in fig. 3), which can be moved down and up as the wick burns. The wick is lowered or raised by turning round the cylinder, HH (shewn separately in figs. 5), by means of its rim, II, fastened to the cylinder, HH, by three small rods, *ii*; the cylinder, HH, fig. 5, has a spiral groove, *kk*, cut obliquely round it: the cylinder, *hh*, figs. 2 and 3, which goes within the cylinder, HH, has a small stub, *l*, projecting from it, which works into the groove, *kk*, fig. 5; the leaf, *l*, is long enough to project a small distance through the groove, *kk*, and when in its place takes against a small bead, *n*, fig. 2, fixed withinside the cylinder, FF, so as to prevent its turning, when HH is turned by its rim, II. By the above arrangement it is evident, that when the cylinder, HH, fig. 5, is turned round, and *h* is prevented from turning, the sides of the groove, *k*, will act as an inclined plane against the stub, *l*, and raise the cylinder *h* down or up, and the cotton wick, *gg*, with it. The rim, II, figs. 1, 2, and 5, has an ornamented border, L, round it, which serves to secure the glass chimney, *o*, from being overthrown. To prevent the cylinder, HH, from being lifted out by accident, it has a rim, *o*, figs. 2 and 5, at the lower end, cut through in one place to allow it to pass down by the bead, *n*; when it is below the end of the bead it cannot be raised, unless the notch in the rim, *o*, corresponds with the bead. When the wick, *gg*, figs. 1 and 5, is lighted, it rarefies the air in the glass chimney, O, and causes a draught through the tube, GG, to supply the inside of the wick, and also under the edge of the glass chimney to supply the outside: as the wick burns down it can be raised from time to time by turning the rim, I, as before described. The tube, FF, is always nearly full of oil, brought by the pipe, D. When it is required to put in a new wick, the glass chimney, O, is lifted off; the tube, *hh*, is screwed up to the top; by turning the rim, II, the tube, fig. 3, is then taken out, the old wick pulled off, and a new one is put round the small part, *m*, of the tube, which is then put in again, and screwed down to the proper depth for lighting the wick.

Rolling-Lamp, a machine, AB (see Pl. Miscel. fig. 145.) with two moveable circles, DE, FG, within; whose common centre of motion and gravity is at K, where their axes of motion cross one another. If the lamp, KC, made pretty heavy, and moveable about its axis, HI, and whose centre of gravity is at C, be fitted within the inner circle, the common centre of gravity of the whole machine will fall between K and C; and by reason of the pivots A, B, D, E, H, I, will be always at liberty to descend: hence, though the whole machine be rolled along the ground, or moved in any manner, the flame will always be uppermost, and the oil cannot spill.

It is in this manner they hang the compass at sea; and thus should all the moon-lanterns be made that are carried before coaches, chaises, and the like.

LAMP-BLACK, among colourmen. See BLACK.

LAMPREY. See PETROMYZON.

LAMPYRIS, *glow-worm*, a genus of insects of the order coleoptera: the generic character is, antennæ filiform; wing-sheaths flexile; thorax flat, semiorbicular, concealing and surrounding the head; abdomen with the sides pleated into papillæ; female (in most species) wingless. The lampyris noctiluca, or common glow-worm, is a highly curious and interesting animal. It is seen during the summer months as late as the close of Aug. if the season is mild, on dry banks, about woods, pastures, and hedgeways, exhibiting, as soon as the dusk of the evening commences, the most vivid and beautiful phosphoric splendour, in form of a round spot of considerable size. The animal itself, which is the female insect, measures about three quarters of an inch in length, and is of a dull earthy brown colour on the upper parts, and beneath, more or less tinged with rose-colour, with the two or three last joints of the body of a pale or whitish sulphur-colour. It is from these parts that the phosphoric light abovementioned proceeds, which is of a yellow colour, with a very slight cast of green: the body, exclusive of the thorax, consists of ten joints or divisions. The larva, pupa, and complete female insect, scarcely differ perceptibly from each other in general appearance, but the phosphoric light is strongest in the complete animal. The glow-worm is a slow-moving insect, and in its manner of walking frequently seems to drag itself on by starts, or slight efforts. The male is smaller than the female, and is provided both with wings and wing-sheaths; and it is but rarely seen.

It is certain, that in some species of this genus the male, as well as the female, is luminous; as in the lampyris Italica, which seems to be a native of our own island also, though less common here than in the warmer parts of Europe. Aldrovandus describes the winged glow-worm as having its wing-shells of a dusky colour, and at the end of the body two brilliant fiery spots like the flame of sulphur. See Plate Nat. Hist. figs. 238, 239.

In the Philosophical Transactions for the year 1684, we find a paper by a Mr. Waller, describing the English flying glow-worm as of a dark colour, with the tail part very luminous. He maintains that both male and female of this species are winged, and that the female is larger than the male: the light of this insect was very vivid, so as to be plainly perceived even when a candle was in the room. Mr. Waller observed this species at Northaw, in Hertfordshire. From the figure given by this writer it appears to be about half an inch in length, which is much smaller than the common female glow-worm.

In Italy this flying glow-worm is extremely plentiful; and we are informed by Dr. Smith and other travellers, that it is a very common practice for the ladies to stick them by way of ornament in different parts of their head-dress during the evening hours.

The common or wingless glow-worm may be very successfully kept, if properly supplied with moist turf, grass, moss, &c. for a considerable length of time; and as soon as the evening commences, will regularly exhibit its beautiful effulgence, illuminating every object within a small space around it, and sometimes the light is so vivid as to be perceived through the box in which it is kept. This insect deposits its eggs, which are small and yellowish, on the leaves of grass, &c. There are 18 species of the lampyris.

LAND, in the sea language, makes part of several compound terms: thus *land-laid*, or to lay the land, is just to lose sight of it. *Land-locked*, is when land lies all round the ship, so that no point of the compass is open to the sea: if she is at anchor in such a place, she is said to ride land-locked, and is therefore concluded to ride safe from the violence of winds and tides. *Land-mark*, any mountain, rock, steeple, tree, &c. that may serve to make the land known at sea. *Land is shut in*, a term used to signify that another point of land hinders the sight of that the ship came from. *Land to*, or the ship lies land to, that is, she is so far from shore that it can only be just discerned. *Land-turn*, is a wind that in almost all hot countries blows at certain times from the shore in the night. *To set the land*, that is, to see by the compass how it bears.

LANDSCAPE. See PAINTING.

LAND-TAX, an antient branch of the public revenue, the origin of which may be traced to the fines or commutations for military service, levied during the feudal system under the name of scutages. These are supposed to have been at first mere arbitrary compositions, as the king and the persons liable could agree; but the practice having been much abused, it was declared by Magna Charta, and afterwards repeatedly confirmed by acts of parliament, that no scutage should be imposed without the consent of the great men and commons, in parliament assembled. This tax was sometimes exacted under the name of hydage, or carrucage; but taxes on land came afterwards to be generally denominated subsidies, or assessments. During the Commonwealth, taxes on land were levied by monthly assessments; and commissioners were appointed in each county for rating the individuals. These assessments varied according to the exigencies of the times, from 35,000*l.* to 120,000*l.* a month; the assessments in Scotland were commonly 6000*l.* but sometimes 1000*l.* a month; in Ireland 9000*l.* a month. This mode of raising money was found so productive, that, with some little variations, it has under the denomination of land-tax ever since formed an important branch of the revenue.

The land-tax, till lately, differed from all the other branches of the public revenue (except part of the duties on malt), in being imposed annually, whereas other taxes have been granted either for a term of years, or, more commonly of late years, for ever; but though granted for only one year at a time, it has been regularly continued from year to year since the Revolution, having never been wholly taken off; but it has varied with respect to the rate at which it has been imposed, having been usually reduced during peace, and increased again in time of war, to answer, in part, the increased expenditure. In 1693 it was first raised to four shillings in the pound, upon a valuation given in in the preceding year, and according to which it has continued to be raised to the present time, at the following rates:

In 1698 and 1699,	at 3*s.*
1700,	at 2*s.*
1701,	at 3*s.*
1702 to 1712,	at 4*s.*
1713 to 1715,	at 2*s.*
1716,	at 4*s.*
1717 to 1721,	at 3*s.*
1722 to 1726,	at 2*s.*
1727,	at 4*s.*
1728 and 1729,	at 3*s.*
1730 and 1731,	at 2*s.*
1732 and 1733,	at 1*s.*
1734 to 1739,	at 2*s.*
1740 to 1749,	at 4*s.*
1750 to 1752,	at 3*s.*
1753 to 1755,	at 2*s.*
1756 to 1766,	at 4*s.*
1767 to 1770,	at 3*s.*
1771,	at 4*s.*
1772 to 1775,	at 3*s.*
1776 to 1798,	at 4*s.*

The sums to be raised at 4*s.* in the pound were stated, in the annual act, at 1,989,673*l.* 7*s.* 10¼*d.* for England, and 47,954*l.* 1*s.* 2*d.* for Scotland, making together 2,037,627*l.* 9*s.* 0¼*d.*; and upon credit of this assessment 2,000,000*l.* was annually borrowed of the Bank in anticipation of the tax, for which sum exchequer-bills were given them, which were to be discharged out of the produce of the tax as it came in; but the full amount of the assessment was seldom, if ever, collected, so that the nett payments into the exchequer always fell short of the sum borrowed on the credit thereof, exclusive of interest on the bills; and the deficiency was made good out of the supplies for the next year.

In 1798 the current value of the public funds having been unusually depressed for some time past, and apprehensions being entertained that the further increase of the funded debt would be attended with peculiar inconvenience, unless some mode was discovered of counteracting its effects, a project was adopted of offering the land-tax for redemption or sale. With this view an act was passed, making the land-tax a perpetual tax, from 25th March, 1799; and being thus converted into a permanent annuity, it was offered for sale to the proprietors of the lands upon which it was charged; or if they declined it, to any other person who chose to become a purchaser. In the first case it was considered as a redemption of the tax, the estate becoming in future wholly freed from it; in the latter case the purchaser became entitled to receive the land-tax regularly from the receiver-general, half-yearly, on the 16th of March and 20th of September in every year. The consideration to be given in either case was not to be in money, but stock, either in the three per cent. consols., or three per cent. reduced, to be transferred to the commissioners for the reduction of the national debt. The quantity of stock to be transferred for redemption of the tax by persons interested in the land on which it was charged, was so much capital as yielded an annuity or dividend exceeding the amount of the tax to be redeemed by one-tenth part thereof; and the stock to be transferred for purchase of the tax by persons not interested in the land, was so much capital as yielded an annuity or dividend exceeding the tax to be purchased by one-fifth part thereof. Thus the amount of three per cent. stock to be transferred for 10*l.* per annum tax was 366*l.* 13*s.* 4*d.* for redemption, or 400*l.* for purchase.

This scheme was adopted with the view of facilitating the raising of money on loan, by absorbing a large quantity of floating stock, and thus raising the current price; while at the same time it would be attended with an increase of revenue. This at least was the avowed object of the measure, which it was estimated would be the means of redeeming or taking out of the market about 80,000,000*l.* of stock; the advantages offered by it were however, by no means such as to induce a general approval of it, many persons subject to the tax declined redeeming it, and but few were inclined to become purchasers. The period first limited was several times extended, but the plan succeeded very imperfectly, and on the 1st February, 1803, the otal amount of 3 per cent. stock, which had been transferred for the redemption of land tax, was only 21,794,307*l.* 17*s.* 3*d.*

LANERIA, a genus of the hexandria monogynia class and order. The corolla is superior, woolly; the caps. three-celled. There is one species, a herb of the Cape.

LANGAYA, a genus of serpents: the generic character is, abdominal plates; caudal rings; terminal scales.

Langaya nasuta, snouted langaya. The genus langaya, consisting of a single species only, differs from all the rest of the serpent tribe in having the upper part or beginning of the tail marked into complete rings or circular divisions resembling those on the body of the amphisbena, while the extreme or terminal part is covered with small scales, as in the genus anguis.

The langaya nasuta, or long-snouted langaya, is in length about two feet eight inches, and its greatest diameter about seven lines: the head is covered with large scales, but the snout, which is extremely long and sharp, projecting to a considerable distance beyond the lower jaw, is covered with very small scales; the teeth, in shape and disposition, resemble those of a viper. The natives of Madagascar are said to hold the langaya in great dread, considering it as a highly poisonous serpent.

LANGUED, in heraldry, expresses such animals whose tongue appearing out of the mouth, is borne of a different colour from that of the body.

LANIUS, the *shrike*, or *butcher-bird*; a genus belonging to the order of accipitres, the characters of which are these: the beak is somewhat straight, with a tooth on each side towards the apex, and naked at the base; and the tongue is lacerated.

1. The excubitor, great cinereous shrike, or greater butcher-bird, is in length 10 inches. The plumage on the upper parts is of a pale ash-colour; the under, white; through the eyes there is a black stripe; the scapulars are white; the base of the greater quills is white, the rest black. The method of killing its prey is singular, and its manner of devouring it not less extraordinary: small birds it will seize by the throat, and strangle; and which probably is the reason the Germans also call this bird wurchangel, or the suffocating angel. It feeds on small birds, young nestlings, beetles, and caterpillars. When it has killed the prey, it fixes them on some thorn, and when thus spitted, pulls them to pieces with its bill. When confined in a cage, they will often treat their food in much the same manner, sticking it against the wires before they devour it. This bird inhabits many parts of Europe and North America. The female makes its nest with heath and moss, lining it with wool and gossamer, and lays six eggs, about as big as those of a thrush, of a dull olive-green, spotted at the thickest end with black. In spring and summer it imitates the voices of other birds, by way of decoying them within reach, that it may destroy them; but beyond this the natural note is the same throughout all seasons. In countries where they are plenty, the husbandmen value them, on supposition of their destroying rats, mice, and other vermin. They are supposed to live five or six years; and are often trained up for catching small birds in Russia.

2. The collurio, or lesser butcher-bird, is seven inches and a half in length. This bird is much more common than the former species. Mr. Latham suspects its being a bird of passage, never having seen it in winter. It lays six white eggs, marked with a rufous brown circle towards the large end. The nest is generally in a hedge or low bush, near which, it is said, no small bird chooses to build; for it not only feeds on insects, but also on the young of other birds in the nest, taking hold of them by the neck, and strangling them, beginning to eat them first at the brain and eyes. It is fonder of grasshoppers and beetles than of other insects, which it eats by morsels, and when satisfied, sticks the remainder on a thorn: when kept in a cage, it does the same against the wires of it, like the former species.

3. The infaustus, or rock shrike, is in length seven inches and three quarters. The bill is about an inch long, and blackish; the head and neck are of a dark ash-colour, marked with small rufous spots; the upper part of the back is a dark brown; the lower much paler, inclining to ash, especially towards the tail; the quills and wing-coverts are dusky, with pale margins; the breast, and under parts of the body, are orange, marked with small spots, some white and others brown. This species is met with in many parts of Europe, from Italy on the one hand, to Russia on the other; and is found in some parts of Germany, the Alpine mountains, those of Tyrol, and such-like places. The manners of this bird seem disputed. It has an agreeable note of its own, approaching to that of the hedge sparrow; and will also learn to imitate that of others. It makes the nest among the holes of the rocks, &c. hiding it with great art; and lays three or four eggs, feeding the young with worms and insects, on which it also feeds itself. It may be taken young from the nest, and brought up as the nightingale.

4. The faustus, or white-wreathed shrike, is about the size of a common thrush. Its bill is pale; the upper parts of the body are grey; the under ferruginous; from the eyes to the hind head there passes a whitish line, composed of numerous white feathers, rendering it truly characteristic; the wings are rounded; the quills brownish, with grey edges, which are crossed with numerous slender brown lines; the tail is rounded, brown, and crossed with numerous bars of darker brown; the legs are pale. This elegant species inhabits China, where it is known by the name of whommaj. It may be observed, among others, in Chinese paper-hangings, where the white line seems to encompass the back part of the head like a wreath.

5. The tyrannus, or tyrant shrike, is about the size of a thrush. Its bill is a blackish brown, beset with bristles at the base; the irides are brown; the upper parts of the plumage grey brown; the under white; the breast inclines to ash-colour; the head is blackish on the upper part; the base of the feathers on that part in the male is orange, but seldom visible except it erects the feathers, when there appears a streak of orange down the middle of the crown. It inhabits Virginia. There is a variety which inhabits St. Domingo and Jamaica. These birds are called titiri, pipiri, or quiquiri, from their cry, which resembles those words. All authors agree in the manners of these birds, which are ferocious to a great degree while the hen is sitting; no bird whatever dare approach their nest; they will attack the first which comes near, without reserve, and usually come off conquerors.

Many species of this genus are found in Cayenne, and other hot countries, as the lanius varius. See Plate Nat. Hist. fig. 240.

LANNIERS, or Lanniards, in a ship, are small ropes reeved into the dead-man's-eyes of all shrowds, either to slacken them or to set them tawt; the stays of all masts are also set tawt by lanniers.

LANTANA, or Indian Sage, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is indistinctly quadridentated; the stigma broken, and turned back like a hoof; the fruit is a plum with a bilocular kernel. There are 19 species, consisting of shrubby exotics from Africa and America for the greenhouse or stove, growing to the height of a yard or two, and adorned with oblong, oval, and roundish simple leaves, with monopetalous, tubular, four-parted flowers of different colours. They may be propagated either by seeds or cuttings. 1. The camara, or wild sage, is remarkable for the beauty of its flowers, which are yellow, tinged with red. 2. The involucrata, or sea-side sage, has small ash-coloured leaves and a most agreeable smell. They are both natives of the West Indies, the former growing wild among the bushes, and the latter being found near the sea. Their leaves, particularly those of the sea-side sage, are used by the black people in teas for colds and complaints of the stomach. 3. The aculeata is a beautiful stove plant, remarkable for its flowers changing from yellow to red. See Plate Nat. Hist. fig. 243.

LANTERN, Magic, an optic machine, whereby little painted images are represented so much magnified, as to be accounted the effect of magic by the ignorant. See Optics.

Lantern. See Architecture.

LAPIDARY. There are various machines employed in the cutting of precious stones, according to the quality: the diamond, which is extremely hard, is cut on a wheel of soft steel, turned by a mill, with diamond-dust, tempered with olive-oil, which also serves to polish it.

The Oriental ruby, sapphire, and topaz, are cut on a copper wheel with diamond-dust, tempered with olive-oil, and are polished on another copper wheel with tripoli and water. The hyacinth, emerald, amethyst, garnets, agates, and other stones, not of an equal degree of hardness with the other, are cut on a leaden wheel with smalt and water, and polished on a tin wheel with tripoli. The turquois of the old and new rock, girasol, and opal, are cut and polished on a wooden wheel with tripoli also.

LAPIS, in general, is used to denote a stone of any kind. See MINERALOGY.

LAPIS *calcedonius*, a genus of stones consisting of silica, a small quantity of alumina, with about one-tenth of lime, and a slight trace of oxide of iron: hard, lightish, shining within, breaking into fragments with sharp edges; compact, not mouldering in the air; of a more or less perfectly conchoidal texture; never opake, tough, admitting of a high polish, and generally of a common form; not melting before the blowpipe. See Plate Nat. Hist. fig. 241.

LAPLYSIA, or SEA-HARE, a genus of marine insects belonging to the order of vermes mollusca. See Plate. The body is covered with membranes reflected. It has a shield-like membrane on the back, a lateral pore on the right side, the anus on the extremity of the back, with four feelers resembling ears. The figure represents the depilans minor, which grows to two inches and a half in length, and to more than an inch in diameter; its body approaches to an oval figure, and is soft, punctated, of a kind of gelatinous substance, and of a pale lead-colour; from the larger extremity there arise four oblong and thick protuberances: these are the tentacula; two of them stand nearly erect, two are thrown backward. It is not uncommon about our shores, especially off Anglesea. It causes, by its poisonous juice, the hair to fall off the hands of those that touch it; and is so extremely fetid as to create sickness at the stomach. The major, or greater sea-hare, grows to the length of eight inches.

LAPPAGO, a genus of the triandria digynia class and order. There is one species, a grass.

LAPSANA, *nipplewort*, a genus of the polygamia æqualis order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the calyx calicu-lated, with all the inferior scales canaliculated or finely channelled. There are five species, which grow commonly as weeds by the sides of ditches. The young leaves of the common kind, called dock-cresses, have the taste of radishes, and are eaten raw at Constantinople as a sallad. In some parts of England the common people boil them as greens, but they have a bitter and disagreeable taste.

LAPSE, the omission of a patron to present to a church, within six months after voidable; by which neglect title is given to the ordinary to collate to such church: and in such case, the patronage devolves from the patron to the bishop, from the bishop to the archbishop, and from the archbishop to the king. A donative does not go in lapse; but the ordinary may compel the patron by ecclesiastical censures to fill up the vacancy. But if the donative has been augmented by the governors of queen Anne's bounty, it will lapse in like manner as presentative livings.

LAPSED LEGACY, is where the legatee dies before the testator; or where a legacy is given upon a future contingency, and the legatee dies before the contingency happens. As if a legacy is given to a person when he attains the age of 21 years, and the legatee dies before that age; in this case the legacy is a lost or lapsed legacy, and shall sink into the residuum of the personal estate. 2 Black. 613.

LARBOARD, among seamen, the left hand side of the ship, when you stand with your face towards the head.

LARCENY, is the felonious and fraudulent taking away of the personal goods of another; which goods, if they are above the value of 12*d.* it is called grand larceny; if of that value or under, it is petit larceny; which two species are distinguished in their punishment, but not otherwise. 4 Black. 229.

The mind only makes the taking of another's goods to be felony, or a bare trespass only; but as the variety of circumstances is so great, and the complications thereof so mingled, it is impossible to prescribe all the circumstances evincing a felonious intent, or the contrary; it must therefore be left to the due and attentive consideration of the judge and jury, wherein the best rule is, in doubtful matters, rather to incline to acquittal, than conviction. But in general it may be observed, that the ordinary discovery of a felonious intent, is, if the party do it secretly, or being charged with the goods deny it. 1 H. H. 509.

As all felony includes trespass, every indictment must have the words feloniously took, as well as carried away: whence it follows, that if the party be guilty of no trespass in taking the goods, he cannot be guilty of felony in carrying them away. 1 Haw. 89.

With respect to what shall be considered a sufficient carrying away, to constitute the offence of larceny; it seems that any the least removing of the thing taken, from the place where it was before, is sufficient for this purpose, though it be not quite carried off. 1 Haw. 93.

As grand larceny is a felonious and fraudulent taking of the mere personal goods of another above the value of 12*d.* so it is petit larceny, where the thing stolen is but of the value of 12*d.* or under. In the several other particulars above-mentioned, petit larceny agrees with grand larceny. 1 Haw. 95.

In petit larceny there can be no accessaries either before or after. 1 H. H. 530.

Larceny from the person. If larceny from the person be done privily without his knowledge, by picking of pockets or otherwise, it is excluded from the benefit of clergy by 8 Eliz. c. 4, provided the thing stolen be above the value of 12*d.* 2 H. H. 336.

But if done openly and avowedly before his face, it is within the benefit of clergy. 1 Haw. 97.

Larceny from the house. Every person who shall be convicted of the feloniously taking away in the day-time, any money or goods of the value of 5*s.* in any dwelling-house, or out-house thereunto belonging, and used to and with the same, though no person be therein, shall be guilty of felony, without benefit of clergy. 39 Eliz. c. 15.

Receiving stolen goods. Any person who shall buy or receive any stolen goods, knowing them to be stolen; or shall receive, harbour, or conceal any felons or thieves, knowing them to be so; shall be deemed accessary to the felony: and being convicted on the testimony of one witness, shall suffer death as a felon convict; but he shall be entitled to his clergy. 5 Anne c. 31.

Any person convicted of receiving or buying stolen goods, knowing them to be stolen, may be transported for fourteen years. 4 Geo. I. c. 11.

Where the principal felon is found guilty to the value of 10*d.* that is, of petit larceny only, the receiver, knowing the goods to have been stolen, cannot be transported for fourteen years, and ought not to be put upon his trial; for the acts which make receivers of stolen goods knowingly, accessaries to the felony, must be understood to make them accessaries in such cases only, where by law an accessary may be; and there can be no accessary to petit larceny. Fost. 74.

Every person who shall apprehend any one guilty of breaking open houses in a felonious manner, or of privately and feloniously stealing goods, wares, or merchandizes, of the value of 5*s.* in any shop, warehouse, coach-house, or stable, though it is not broken open, and though no person is therein to be put in fear, and shall prosecute him to conviction, shall have a certificate without fee, under the hand of the judge, certifying such conviction, and within what parish or place the felony was committed, and also that such felon was discovered and taken, or discovered or taken, by the person so discovering or apprehending; and if any dispute arise between several persons so discovering or apprehending, the judge shall appoint the certificate into so many shares, to be divided among the persons concerned, as to him shall seem just and reasonable. Leache's Cro. Law, 307. See BURGLARY.

LARK. See ALAUDA.

LARKSPUR. See DELPHINIUM.

LARVA, in natural history, a name given by Linnæus to insects in that state, called by other writers eruca, or caterpillar.

LARUS, the *gull*, a genus in the order of anseres, the characters of which are: the bill is straight, cultrated, a little crooked at the point, and without teeth; the inferior mandible is gibbous below the apex; the nostrils are linear, a little broader before, and situated in the middle of the beak. The different species are principally distinguished by their colour. The most remarkable are,

1. The marinus, or black-backed gull, in length 29 inches, in breadth five feet nine. The bill is very strong and thick, and almost four inches long; the colour a pale yellow; the head, neck, whole under-side, tail, and lower part of the back, are white; the upper part of the back and wings are black; the quill-feathers tipt with white; the legs of a pale flesh-colour. It inhabits several parts of England, and breeds on the highest cliffs. The egg is blunt at each end, of a dusky olive-colour, quite black at the greater end, and the rest of it thinly marked with dusky spots. It is also common on most of the northern coasts of Europe. It frequents Greenland, but chiefly inhabits the distant rocks. It lays there eggs in May, placing them on the heaps of dung which the birds leave there from time to time. It is said to attack other birds, and to be particularly an

enemy to the eider duck. It very greedily devours carrion, though its most general food is fish. It is common also in America, as low as South Carolina, where it is called the old-wife.

2. The cataractes, or Skua gull, is in length two feet; the extent four feet and a half; the weight three pounds; the feathers on the head, neck, back, scapulars, and coverts of the wings, are of a deep brown, marked with rust-colour (brightest in the male). The breast, belly, and vent are ferruginous, tinged with ash-colour. This bird inhabits Norway, the Ferroe isles, Shetland, and the noted rock Foula a little west of them. It is also a native of the South Sea. It is the most formidable of the gulls; its prey being not only fish, but what is wonderful in a web-footed bird, all the lesser sort of water-fowl, such as teal, &c. Mr. Schroter, a surgeon in the Ferroe isles, relates that it likewise preys on ducks, poultry, and even young lambs. The natives of the Orkneys are often very rudely treated by them while they are attending their sheep on the hills, and are obliged to guard their heads by holding up their sticks, on which the birds often kill themselves. In Foula it is a privileged bird, because it defends the flocks from the eagle, which it beats and pursues with great fury; so that even that rapacious bird seldom ventures near its quarters.

3. The parasiticus, or dung-hunter, is in length 21 inches: the upper parts of the body, wings, and tail, are black; the base of the quills white on the inner webs; and the two middle feathers of the tail are near four inches longer than the rest. This is a northern species, and very common in the Hebrides, where it breeds on heath. It comes in May, and retires in August; and if disturbed flies about like the lapwing, but soon alights. It is also found in the Orkneys; and on the coasts of Yorkshire, where it is called the feaser. This bird does not often swim, and flies generally in a slow manner, except in pursuit of other birds, which it often attacks, in order to make them disgorge the fish or other food which this common plunderer greedily catches up.

4. The canus, or common gull, is in length 16 or 17 inches; in breadth 36; weight one pound. The bill is yellow; the head, neck, under parts of the body and tail are white; the back and wings pale-grey. It is a tame species, and may be seen by hundreds on the shores of the Thames and other rivers, in the winter and spring, at low tides, picking up the various worms and small fish left by the tides; and will often follow the plough in the fields contiguous, for the sake of worms and insects which are turned up; particularly the cockchafer or dorbeetle in its larva state, which it joins with the rooks in devouring most greedily.

5. The tridactylus, or tarrock, is in length 14 inches, breadth 36; weight seven ounces. The head, neck, and under parts, are white; near each ear, and under the throat, there is a black spot; and at the hind part of the neck a crescent of black; the back and scapulars are blueish-grey; the wing-coverts dusky edged with grey, some of the larger wholly grey. This species breeds in Scotland, and inhabits other parts of northern Europe, quite to Iceland and Spitzbergen. It is observed frequently to attend the whales and seals, for the sake of the fish which the last drive before them into the shallows, when these birds dart into the water suddenly, and make them their prey.

6. The ridibundus, peewit, or black-head gull, is in length 15 inches, breadth three feet; weight ten ounces; the back and wings are of an ash-colour; the neck, all the under parts, and tail, are white; the first ten quills are white, margined, and more or less tipped with black; the others of an ash-colour. This species breeds on the shores of some of our rivers; but full as often in the inland fens of Lincolnshire, Cambridgeshire, and other parts of England. They make their nest on the ground, with rushes, dead grass, &c. and lay three eggs of a greenish brown, marked with red-brown blotches. After the breeding season, they again disperse to the sea-coasts. The young birds in the neighbourhood of the Thames are thought good eating, and are called the red legs. They were formerly more esteemed, and numbers were annually taken and fattened for the table. Whitelock, in his annals, mentions a piece of ground near Portsmouth, which produced to the owner 40*l.* a year by the sale of peewits, or this species of gull. These are the sea-gulls that in old times were admitted to the noblemen's tables. The note of these gulls is like a hoarse laugh.

7. The atricilla, or laughing gull, is in length 18 inches, breadth three feet. It is found in Russia on the river Don, particularly about Tschercask. The note resembles a coarse laugh, whence the name of the bird. It is met with also in different parts of the continent of America, and is very numerous in the Bahama islands.

There are 14 or 15 other species of this genus. See Plate Nat. Hist. fig. 242.

LARYNX. See Anatomy.

LASH, or Lace, in the sea language, signifies to bind and make fast.

LASERPITIUM, *lazar-wort*, a genus of the digynia order, in the pentandria class of plants, and in the natural method ranking under the 45th order, umbellatæ. The fruit is oblong, with eight membranaceous angles; the petals inflexed, emarginated, and patent. There are 15 species, none of which are at all remarkable for their beauty, so are only preserved in botanic gardens for the sake of variety.

LASIOSTOMA, a genus of the class and order tetrandria monogynia: the calyx is very short, five-petalled; corolla funnel-form, four-cleft; caps. orbiculate, one-celled, two-seeded. There is one species, a shrub of Guiana.

LASKETS, small lines, like loops, sewed to the bonnets and drablers of a ship, to lash or lace the bonnets to the courses, or the drablers to the bonnets.

LASKING, at sea, is much the same with going large, or veering, that is, going with a quarterly wind.

LAST, in general, signifies the burden or load of a ship. It signifies also a certain measure of fish, corn, wool, leather, &c. A last of codfish, white herrings, meal, and ashes for soap, is 12 barrels; of corn or rapeseed, 10 quarters; of gunpowder 24 barrels; of red-herrings 20 cades; of hides 12 dozen; of leather 20 dickers; of pitch and tar 14 barrels; of wool 12 sacks; of stock-fish 1000; of flax or feathers 1700 pounds.

LATH, in building, a long, thin, and narrow slip of wood, nailed to the rafters of a roof or ceiling, in order to sustain the covering. These are distinguished into three kinds, according to the different kinds of wood of which they are made, viz. heart of oak, sap-laths, and deal-laths; of which the last two are used for ceilings and partitions, and the first for tiling only. Laths are also distinguished according to their length, into five-feet, four-feet, and three-feet laths, though the statute allows but of two lengths, those of five and those of three feet, each of which ought to be an inch and a half in breadth, and half an inch in thickness, but they are commonly less.

LATHE, a very useful engine for the turning of wood, ivory, metals, and other materials. The invention of the lathe is very antient; Diodorus Siculus says, the first who used it was a grandson of Dædalus, named Talus. Pliny ascribes it to Theodore of Samos, and mentions one Thericles, who rendered himself very famous by his dextery in managing the lathe. With this instrument the antients turned all kinds of vases, many whereof they enriched with figures and ornaments in basso relievo. Thus Virgil: "Lenta quibus torno facili superaddita vitis." The Greek and Latin authors make frequent mention of the lathe; and Cicero calls the workmen who used it vascularii. It was a proverb among the antients, to say a thing was formed in the lathe, to express its delicacy and justness.

The lathe is composed of two wooden cheeks or sides, parallel to the horizon, having a groove or opening between; perpendicular to these are two other pieces called puppets, made to slide between the cheeks, and to be fixed down at any point at pleasure. These have two points, between which the piece to be turned is sustained; the piece is turned round, backwards and forwards, by means of a string put round it, and fastened above to the end of a pliable pole, and underneath to a treadle or board moved with the foot. There is also a rest which bears up the tool, and keeps it steady.

The most simple kind of lathe is too well known to require a more ample description. We shall therefore give a figure of an improved lathe manufactured by Mr. Maudslay of Margaret-street. A (Plate Miscel. fig. 138.) is the great wheel, with four grooves on the rim: it is worked by a crank B and treadle C, in the common way; the catgut which goes round this wheel passes also round a smaller wheel D, called the mandrel, which has four grooves on its circumference of different diameters for giving it different velocities, corresponding with the four grooves on the great wheel A. In order to make the same band suit when applied to all the different grooves on the mandrel D, the wheel A can be elevated or depressed by a screw *a*, and another at the other end of the axle; and the connecting rod C can be lengthened or shortened by screwing the hooks at each end of it further out of, or into it. The end M, fig. 139. of the spindle of the mandrel D, is pointed, and works in a hole in the end of a screw, put through the standard E, fig. 138.; the other end of the bearing F, fig. 139. is conical, and works in a conical socket in the standard, so that by tightening up the screw in E, the conical end F may at any time be made to fit its socket: the puppet G has a cylindric hole through its top to receive the polished pointed rod *d*, which is moved by the screw *e*, and fixed by the screw *f*; the whole puppet is fixed on the triangular prismatic bar H, by a clamp fig. 143. the two ends of which, *a*, *b*, are put through holes *b*, in the bottom of the puppet under the bar, and the whole is fixed by the screw *c* pressing against it; by this means the puppet can be taken off the bar without first taking off the standard I, as in the common lathes; and the triangular bar is found to be far preferable to the double rectangular one in common use. The rest J is a similar contrivance; it is in 3 pieces; see figs. 140, 141, 142. Fig. 141 is a piece, the opening (*a*, *b*, *c*) in which is laid upon the bar H, fig. 138.; the four legs *d d d d* of fig. 142. are then put up under the bar (into the recesses in fig. 141. which are made to receive them), so that the notches in *d d d d* may be level with the top of fig. 141.: the two beads *e f* in fig. 140. are then slid into the notches in the top of *d d d d*, to keep the whole together; the groove *i* is to receive a corresponding piece on *e f*, fig. 140., to steady it; the whole of fig. 140. has a metallic cover, to keep the chips out of the grooves. It is plain, that by tightening the screw *h* in the bottom of figs. 138. and 142., the whole will be fixed and prevented from sliding along the bar H, and fig. 140. from sliding in a direction perpendicular to the bar; the piece *l*, on which the tool is laid, can be raised or lowered at pleasure, and fixed by the screw *m*. On the end *n* of the spindle P, figs. 138. and 139., is screwed occasionally an universal chuck for holding any kind of work which is to be turned (fig. 144.). A is the female screw to receive the screw *n*, fig. 138.; near the bottom of the screw A is another BB, which is prevented from moving endways by a collar in the middle of it fixed to the screw A: one end of the screw BB is cut right-handed, and the other left-handed, so that by turning the screw one way, the two nuts EF will recede from each other, or by turning it the contrary way, they will advance towards each other; the two nuts EF pass through an opening in the plate C, and project beyond the same, carrying jaws like those of a vice, by which the subject to be turned is held.

The large lathes which Mr. Maudslay uses in his manufactory, instead of being worked by the foot, as represented in fig. 138., are worked by hand; the wheel and fly-wheel which the men turn work by a strap on another wheel, fixed to the ceiling directly over it; on the axis of this wheel is a larger one, which turns another small wheel or pulley, fixed to the ceiling, directly over the mandrel of the lathe; and this last has on its axis a larger one which works the mandrel D, by a band of catgut. These latter wheels are fixed in a frame of cast iron, moveable on a joint; and this frame has always a strong tendency to rise up, in consequence of the action of a heavy weight; the rope from which, after passing over a pulley, is fastened to the frame. This weight not only operates to keep the mandrill-band tight, when applied to any of the grooves therein, but always makes the strap between the two wheels on the ceiling fit. As it is necessary that the workman should be able to stop his lathe, without the men stopping who are turning the great wheel, there are two pulleys, or rollers, (on the axis of the wheel over the lathe) for the strap coming from the other wheel, on the ceiling; one of these pulleys, called the dead pulley, is fixed to the axis, and turns with it; and the other which slips round it, is called the live pulley: these pulleys are put close to each other, so that by slipping the strap upon the live pulley, it will not turn the axis; but if it is slipped on the other, it will turn with it: this is effected by an horizontal bar, with two upright pins in it, between which the strap passes. This bar is moved in such a direction as will throw the strap upon the live pulley, by means of a strong bell-spring; and in a contrary direction it is moved by a cord fastened to it, which passes over a pulley, and hangs down within reach of the workman's hand: to this cord is fastened a weight, heavy enough to counteract the bell-spring, and bring the strap up to the dead pulley, to turn the lathe; but when the weight is laid upon a little shelf, prepared for the purpose, the spring will act and stop it.

The following is a description of Mr. Smart's newly invented lathe for turning cylinders of wood for the purpose of tent-poles, pickets, handles for tools, &c. &c. the operations of which are so readily performed, that from octagonal bars of yellow deal, 5½ feet long (previously prepared by means of a circular saw) one man, besides two labourers to turn the wheel, will turn out 600 perfectly cylindrical poles, in the space of 12 hours. AA, fig. 6., (Plate Smart's lathe) represents the standards for supporting the great wheel, that gives motion to the lathe; these are supported by pieces of board BB spiked to the ceiling or joists above, and by others CC affixed to the floor of the workshop. The great wheel DD is grooved round the edge for receiving the endless screw B and E, E, and is put in motion by the winch-handle F F. G and H are the standards of the lathe, firmly fixed to the floor, and carrying the side-pieces or bed II; the standard G is tall enough to act as a fixed puppet, and has a screw *a* working through it, for supporting the end of the mandrel or spindle of this lathe, as in the common lathe. K, L, and M, are three other puppets that can be fixed in any place desired, by wedges beneath the bed as usual. To the puppet K is screwed a thick iron plate *b*, which has a conical socket, nicely turned and polished, for receiving the mandrel: this puppet is further steadied by a brace N, screwed to it, and to the floor of the shop. To the puppet K and L two bars *oo* are fixed by screws, and the same are further supported and steadied by three short puppets P P P. The mandrel, and its pulley Q, are nearly of the common construction, except that the end *c* has a steel point in its centre, and two shorter points for preventing the octagonal piece of wood intended to be turned from slipping or turning without the mandrel. The puppet L has a square-pointed bar *d* fitted to it; and the puppet M has a screw, worked by its handle *e*, which by means of a collar advances or draws back the bar *d*. R is a piece of wood, fixed to the bed and to the floor, for the purpose of carrying a pulley *f*, whose use is to prevent the wheel-band EE from wearing by friction at the place where it crosses. Figs. 7. and 8. represent the gouge and plane, successively used instead of the common turner's chisel, &c.: the pieces of board *aa* are screwed to the block *b*, just at the proper distance of the outsides of the bars *oo*, fig. 1., so that when the tools, figs. 7. and 8. are placed on them, they can be slid along steadily, between the puppets K and L; the holes *cc* being so adapted as to suit the mandrel and bar *c* and *d* as centres, and their diameters are sufficient to let the octagonal bar intended to be turned pass through them, without touching; *d*, fig. 7., is a piece of tempered steel, formed as a gouge, and screwed fast to the side of the block, in the proper position for roughing off the angles of the octagonal bar, as it advances, and turns through the hole *c*. *c* fig. 7., is a flat piece of steel, like a plane-iron (shewn separately at *f*), which is so fixed by a screw, that it may smooth or complete the cylindrical surface of a pole, already gouged as above, which is advanced, and turned through it. The operation is thus performed: The two tools figs. 7 and 8, are placed on the bar *oo*, fig. 6, and shoved close up to the puppet L; the square bar being long enough for its point *d*, then to project through the centres of the holes *cc*, figs. 7 and 8. The workman then takes an octagonal pole, enters the centre pin of the mandrel *c* into the centre of its end, and the point *d* into the centre of the other end, turning the handle *e* sufficiently to allow the pole to be steadily turned: the wheel D is then set in motion; the workman pushes the gouge-tool, fig. 8., forwards, towards the puppet K, which, as it advances quickly, strikes off the angles of the pole in a rough or screw-like form. When the gouge-tool, fig. 8., has advanced to the end of the pole, the finishing-tool, fig. 7., is in like manner shoved forwards by the workman; and as it advances, the pole is turned into a complete and smooth cylinder. The projection of the mandrel *bc*, fig. 6, is sufficient to admit the gouge and plane tools, to advance so as to clear the end of the pole; and by turning back the handle *e*, the same can be taken out of the lathe as soon as it is stopped. The velocity of the mandrel Q is such, as to make upwards of 1200 turns per minute.

LATHRÆA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is quadrifid; there is a depressed glandule at the base of the suture of the germen. The capsule is unilocular. There are four species.

LATHS, *cleaving of*. The lath-cleavers having cut their timbers into lengths, cleave each piece with wedges into 8, 12, or 16, according to the size of their timber; these pieces are called bolts: this is done by the felt-grain, which is that grain which is seen to run round in rings at the end of a piece of a tree. Thus they are cut out for the breadth of the laths, and this work is called felting. Afterwards they cleave the laths into their proper thicknesses with their chit, by the quarter-grain, which is that which runs in straight lines towards the pith.

LATHYRUS, *chickling vetch*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The stylus is plain, villous above, towards the end broader; the upper two segments of the calyx are shorter than the rest.

The species are 23, among which are: 1. The latifolius, or everlasting pea. 2. The odorata, or sweet-scented pea. 3. The tangitanus, or Tangier pea, also an annual, and well known.

LATITAT, a writ whereby all men in personal actions are called originally to the king's bench. F. N. B. 78.

A latitat may be considered either as the commencement of the action, or only as a process to bring the defendant into court, at the election of the plaintiff. Bul. N. P. 151.

If it is stated as the commencement of the action to avoid a tender, the defendant may deny that the plaintiff had any cause of action at the time of suing it out. 1 Wils. 141.

Or if it is replied to a plea of the statute of limitations, the defendant, in order to maintain his plea, may aver the real time of suing it out, in opposition to the test. 2 Burr. 950. See Impey's B. R. and C. B. Practice.

LATITUDE. See GEOGRAPHY.

LATITUDE. See ASTRONOMY.

LATTEN denotes iron plates tinned over, of which tea-canisters are made.

LATTEN-BRASS, plates of milled brass, reduced to different thickness, according to the uses it is intended for.

LATUS RECTUM, in conic sections, the same with parameter. See CONIC SECTIONS.

LATUS TRANSVERSUM, in the hyperbola, that part of the transverse diameter, intercepted between the vertices of the two opposite sections.

LAVANDULA, *lavender*: a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 42 l order, verticillatæ. The calyx is ovate, and a little dentated, supported by a bractea or floral leaf; the corolla is resupinated; the stamina within the tube.

The species are seven in number, among which are: 1. The spica, or spike lavender, has a short shrubby stalk. The varieties of this are: common narrow-leaved lavender, with blue flowers, and with white flowers; broad-leaved lavender; dwarf lavender: all of them flowering in July. This species is the common lavender; but the narrow-leaved variety, with blue flowers, is the sort commonly cultivated for its flowers for medicine. 2. The stœchas, or French lavender, has a shrubby very branchy stalk, rising two or three feet high; very narrow, spear-shaped, pointed, hoary leaves, opposite; and all the branches terminated by short bushy spikes of purple flowers in June and July, succeeded by seeds in August. There is a variety with white flowers. 3. The dentata, or dentate-leaved stœchas, has a woody stalk, branching on every side three or four feet high; leaves deeply indented in a pinnated manner; and the branches terminated by scaly four-cornered spikes of flowers, appearing most part of summer.

The first two species are proper for the kitchen-garden, and for medicinal and other family uses, and to plant in the pleasure-ground to adorn the front of small shrubbery compartments, where they will increase the variety very agreeably; and are finely scented aromatics, both when growing, and their flowers when gathered; especially those of the first species, which are in great esteem for putting among clothes, and for distilling, and other economical uses. The flowers of the first sort are gathered for use in July.

LAVATERA, a genus of the polyandria order, in the polydelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The exterior calyx is double and trifid; the arilli or seed-coats are very many and monospermous. There are 9 species, most of them herbaceous flowery annuals, or shrubby perennials, growing erect from two or three to eight or ten feet high. They are easily propagated by seed in the open ground in the spring, and thrive best when sown where they are designed to remain.

LAUDANUM. See PHARMACY.

LAUGERIA, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking among those of which the order is doubtful. The corolla is quinquefid; the fruit is a plum with a quinquelocular kernel. There are two species, shrubs of the West Indies.

LAUNCH, in the sea-language, signifies to put out: as, launch the ship, that is, put her out of the dock; launch aft, or forward, speaking of things that are stowed in the hold, is, put them more forward; launch, ho! is a term used when a yard is hoisted high enough, and signifies hoist no more.

LAUNDER, among miners, a place where they wash the powdered ore.

LAUREATION, in the universities of Scotland, signifies the act of taking the degree of master of arts, which the students are permitted to do after four years study.

LAURUS, *the bay-tree*, a genus of the monogynia order, in the enneandria class of plants, and in the natural method ranking under the 12th order, holoraceæ. There is no calyx; the corolla is calycine, or serving in place of the calyx, and sexpartite: the nectarium with three glandules, each terminated by two bristles surrounding the germen. The interior filaments furnished with glandules at the base; the fruit a monospermous plum. There are 32 species, of which the most noted are: 1. The nobilis, or evergreen bay-tree, a native of Italy, and has an upright trunk branching on every side from the bottom upward, with spear-shaped, nervous, stiff, evergreen leaves, three inches long, and two broad; and small, yellowish, quadrifid, diœcious flowers, succeeded by red berries in autumn and winter. Of this species there are varieties, with broad, narrow, striped, or waved leaves. 2. The æstivalis, or deciduous bay, grows naturally in North America. It rises with an upright stem, covered with a purplish bark, having oblong, oval, acuminated, veined, deciduous leaves, two or three inches long, and half as broad, growing opposite, with small white flowers succeeded by red berries. 3. The benzoin, or benjamin tree, is also a native of North America; grows 15 or 20 feet high, divided into a very branchy head, with oval, acute, deciduous leaves, three or four inches long, and half as broad; and small yellowish flowers, not succeeded by berries in this country. This, it is to be remarked, is not the tree which bears the gum benzoin, that being a species of hyrax. 4. The sassafras is a native of the same country. It has a shrub-like straight stem, with both oval and three-lobed, shining, deciduous leaves, of different sizes, from three to 6 inches long, and nearly as broad, with small yellowish flowers succeeded by blackish berries, but not in this country. 5. The indica, or Indian bay-tree, rises with an upright straight trunk, branching regularly 20 or 30 feet high, adorned with very large, spear-shaped, plane, nervous, evergreen leaves on reddish footstalks; and bunches of small whitish-green flowers, succeeded by large oval black berries, which do not ripen in this country. 6. The barbonia, or Carolina red bay-tree, rises with an upright straight stem, branching 15 or 20 feet high; with large, spear-shaped, evergreen leaves, transversely veined; and long bunches of flowers on red footstalks, succeeded by large blue berries sitting in red cups. 7. The camphora, or camphor-tree, grows naturally in the woods of the western parts of Japan, and in the adjacent islands. See Plate Nat. Hist. fig. 244. The root smells stronger of camphor than any of the other parts, and yields it in greater plenty. The bark of the stalk is outwardly somewhat rough; but in the inner surface smooth and mucous, and therefore easily separated from the wood, which is dry, and of a white colour. The flowers are produced on the tops of footstalks, which proceed from the armpits of the leaves; but not till the tree has attained considerable age and size. The flower-stalks are slender, branched at the top, and divided into very short pedicles, each supporting a single flower. These flowers are white, and consist of six petals, which are succeeded by a purple and shining berry of the size of a pea, and in figure somewhat top-shaped. It is composed of a soft pulpy substance, that is purple, and has the taste of cloves and camphor; and of a nucleus or kernel of the size of a pepper, which is covered with a black, shining, oily corticle, of an insipid taste. 8. The cinnamomum, or cinnamon-tree, is a native of Ceylon. It has a large root, and divides into several branches, covered with a bark, which on the outer side is of a greyish brown, and on the inside has a reddish cast. The wood of the root is hard, white, and has no smell. The body of the tree, which grows to the height of 20 or 30 feet, is covered, as well as its numerous branches, with a bark which at first is green and afterwards red. The leaf is longer and narrower than the common bay-tree; and it is three-nerved, the nerves vanishing towards the top. When first unfolded, it is of a flame-colour; but after it has been for some time exposed to the air, and grows dry, it changes to a deep green on the upper surface, and to a lighter on the lower. The flowers are small and white, and grow in large bunches at the extremity of the branches: they have an agreeable smell, something like that of the lily of the valley. The fruit is shaped like an acorn, but is not so large. 9. The cassia, or base cinnamon, has lanceolated leaves, triple-nerved. 10. The persea, avocado-pear tree, or alligator pear, rises to a considerable height, with a straight trunk, of which the bark and wood are of a greyish colour. The leaves are long, oval, pointed, of a substance like leather, and of a beautiful green colour. The flowers are produced in large knots or clusters at the extremities of the branches, and consist each of six petals disposed in the form of a star, and of a dirty-white or yellow colour, with an agreeable odour, which diffuses itself to a considerable distance. It is a native of the West Indies. The persea begins to bear two years and a half, or at most three years, after being planted; and like most of the trees in warm climates, bears twice a year.

LAW. Laws of England are divided into lex non scripta, or the common law; and lex scripta, or statute law.

The lex non scripta is not so called from its being conveyed down from former ages by word of mouth, but because the original authority of these laws is not set down in writing, and they receive their force by long usage, and by their universal reception throughout the kingdom; and it is curious to observe, that these rude maxims of our ancestors, of which no person knows clearly the origin, exceed in clearness, brevity, and authority, all that the united wisdom of the most enlightened men have produced in later ages.

The common law is divided into:

1st. General custom, which is the universal rule of the whole kingdom, and is the law by which proceedings and determinations in the courts of justice are ordinarily directed. This for the most part settles the course of inheritance, the manner and form of acquiring and transferring property, the solemnities and obligations of contracts, the rules of expounding wills, deeds, and acts of parliament; the remedies of civil injuries, the different kinds of offences with the punishments allotted to each; the institution of four superior courts of record; and many other particulars which diffuse themselves as extensively as the distribution of common justice requires, all of which are not enacted by any particular statutes (though they are acknowledged by all) but depend entirely upon the common law.

2dly. Particular customs which concern the inhabitants of some particular district.

3dly. The third branch are those laws which are adopted by certain courts and jurisdictions, as the civil and canon laws.

The civil law is understood to signify the civil law of the Roman empire. The canon law is a body of Roman ecclesiastical law relating to matters over which the church exercises a jurisdiction. The civil law is used in four courts under certain restrictions, viz. the archbishops' and bishops' courts, usually styled curiæ christianitatis; the courts martial, the courts of admiralty, and the courts of the two universities.

The second division of the laws of England are the statutes made by the king, lords, and commons, assembled in parliament. The oldest statute extant is the celebrated Magna Charta, 9 Hen. 3; though, doubtless, the records of many antecedent to that have been lost, and the maxims received as common law.

Statutes are general or special, public or private: general or public acts are those which concern the whole nation; of these the judges are obliged to take notice, though they should not be formally pleaded by the party who claims an advantage under them. Special or private acts are such as operate on private persons and concerns, which must be formally set forth by the party, or the judges are not obliged to notice them.

Statutes are either declaratory of the common law, where it is become disreputable, or fallen into disuse; or remedial, when made to supply the defects, or abridge the superfluities of the common law. These latter are subdivided into enlarging and restraining statutes, by enlarging the common law where it was too circumscribed, and restraining it where it was too luxuriant.

There is besides those grounds of the laws of England, a court of equity to moderate and explain them. (See Equity.) The courts of equity are, however, only had recourse to in matters of property; for our constitution will not permit, that in criminal cases any judge should have the power of construing the law otherwise than according to the letter. This caution, while it protects the public liberty, can never oppress the individual. A man cannot suffer more punishment than the law directs, but he may suffer less. The laws cannot be strained to inflict a penalty beyond what the letter warrants, but in cases where the letter induces any apparent hardship, the crown has power to pardon.

In treating of the laws, the best mode, and which has been adopted by sir William Blackstone in his excellent Commentaries, after the example of Wood in his Institutes, is to divide them, 1st, into the rights of persons, or the rights as to personal security, personal liberty, and private property. 2nd, The rights of things, or the rights which a man may acquire in and to such external things as are unconnected with his person. 3rd. Private wrongs, or such as are the infringement of the private rights of individuals: and 4th. public wrongs, or such as are a violation the public rights, and affect the whole community.

It is of course unnecessary, and perhaps in a work of this nature irrelevant, to recommend the study of the law; it is sufficient to add the words of the great judge Blackstone on this subject. "It is incumbent (says he) upon every man to be acquainted with the laws, lest he incur the censure as well as the inconvenience of living in society without knowing the obligations it lays him under."

LAVENIA, a genus of the class and order syngenesia polygamia æqualis. The calyx is nearly regular; style bifid; down three-awned; recept. naked. There are two species, herbs of the East and West Indies.

LAWSONIA, *Egyptian privet*, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is quadrifid; the petals four; the stamina four, in pairs; the capsule is quadrilocular and polyspermous. There are four species, all natives of India. Some authors take the inermis to be the plant termed by the Arabians henna or alhenna, the pulverised leaves of which are much used by the Eastern nations for dyeing their nails yellow; but others, Dr. Hasselquist in particular, attribute that effect to the leaves of the other species of Egyptian privet which bears prickly branches. It is probable that neither set of writers are mistaken, and that the shrub in question is a variety only of the thorny lawsonia, rendered mild by culture.

LAY-BROTHERS, among the Romanists, those pious, but illiterate persons, who devote themselves, in some convent, to the service of the religious. They wear a different habit from that of the religious, but never enter into the choir, nor are present at the chapters; nor do they make any other vow, except of constancy and obedience. In nunneries there are also lay-sisters.

Lay-man, among painters, a small statue either of wax or wood, whose joints are so formed, that it may be put into any attitude or posture. Its principal use is for adjusting the drapery in clothing of figures.

LAYERS, in gardening, are tender shoots or twigs of trees, laid or buried in the ground, till, having struck root, they are separated from the parent tree, and become distinct plants. The propagating trees by layers is done in the following manner: the branches of the trees are to be slit a little way, and laid under the mould for about half a foot: the ground should be first made very light, and after they are laid they should be gently watered. If they will not remain easily in the position they are put in, they must be pegged down with wooden hooks: the best season for doing this is, for evergreens, toward the end of August, and for other trees in the beginning of Feb. If they are found to have taken root, they are to be cut off from the main plant the succeeding winter, and planted out. If the branch is too high from the ground, a tub of earth is to be raised to a proper height for it. Some pare off the rind, and others twist the branch before they lay it: but this is not necessary. The end of the layer should be about a foot out of the ground; and the branch may be either tied tight round with a wire, or cut upwards from a joint, or cut round for an inch or two at the place, and it is a good method to pierce several holes through it with an awl above the part tied with the wire.

LAZAR-HOUSE, or Lazaretto, a public building, in the nature of an hospital, to receive the poor and those afflicted with contagious distempers: in some places lazarettos are appointed for the performance of quarantine; in which case, those are obliged to be confined in them who are suspected to have come from places infected with the plague. This is usually a large building, at some distance from a city, whose apartments stand detached from each other, where vessels are unladen, and the crew shut up for about 40 days, more or less, according to the time and place of their departure. The lazaretto of Milan is esteemed one of the finest hospitals in Italy.

LAZULITE. This stone, which is found chiefly in the northern parts of Asia, was long known to mineralogists by the name of lapis lazuli.

Lazulite is always amorphous. Its texture is earthy. Its fracture uneven. Lustre 0. Opaque, or nearly so. Hardness 8 to 9. Specific gravity 2.76 to 2.945. Colour blue; often spotted white from specks of quartz, and yellow from particles of pyrites.

It retains its colour at 100° Wedgewood; in a higher heat it intumesces, and melts into a yellowish-black mass. With acids it effervesces a little, and if previously calcined, forms with them a jelly.

Margraff published an analysis of lazulite in the Berlin Memoirs for 1758. His analysis has since been confirmed by Klaproth, who found a specimen of it to contain

46.0	silica
14.5	alumina
28.0	carbonat of lime
6.5	sulphat of lime

3.0 oxide of iron
2.0 water

100.0

From the experiments of Morveau, it appears that the colouring matter of lazulite is sulphuret of iron.

LEAD, one of the perfect metals, appears to have been very early known. It is mentioned several times by Moses. The antients seem to have considered it as nearly related to tin. It is of a blueish-white colour; and when newly melted is very bright, but it soon becomes tarnished by exposure to the air. It has scarcely any taste, but emits on friction a peculiar smell. It stains paper or the fingers of a blueish colour. When taken internally, it acts as a poison. Its hardness is $5\frac{1}{2}$; its specific gravity is 11.3523. Its specific gravity is not increased by hammering, neither does it become harder, as is the case with other metals; a proof that the hardness which metals assume under the hammer is in consequence of an increase of density. It is very malleable, and may be reduced to very thin plates by the hammer; it may be also drawn out into wire, but its ductility is not great. Its tenacity is such, that a lead wire only $\frac{1}{120}$ inch diameter is capable of supporting 18 pounds without breaking. It melts, according to sir Isaac Newton, when heated to the temperature of 540° Fahrenheit: but Morveau makes its fusing point as high as 594°. When a very strong heat is applied, the metal boils and evaporates. If it is cooled slowly, it crystallizes. The abbé Mongez obtained it in quadrangular pyramids, lying on one of their sides. Each pyramid was composed apparently of three layers. Pajot obtained it in the form of a polyhedron with 32 sides, formed by the concourse of six quadrangular pyramids.

When exposed to the air, it soon loses its lustre, and acquires first a dirty-grey colour, and at last its surface becomes almost white. This is owing to its gradual combination with oxygen, and conversion into an oxide; but this conversion is exceedingly slow; the external crust of oxide, which forms first, preserving the rest of the metal for a long time from the action of the air.

Water has no direct action upon lead; but it facilitates the action of the external air. For when lead is exposed to the air, and kept constantly wet, it is oxidated much more rapidly than it otherwise would be. Hence the reason of the white crust which appears upon the sides of leaden vessels containing water, just at the place where the upper surface of the water usually terminates.

No less than four different combinations of lead with oxygen are at present known, though some of them have not been examined with much attention.

1. The protoxide, or first oxide of lead, may be obtained by dissolving lead in nitric acid, and boiling the crystals which that solution yields by concentration along with pieces of metallic lead. The consequence is the formation of scaly crystals of a yellow colour, brilliant, and very soluble in water. These crystals are composed of the protoxide of lead combined with nitric acid. The protoxide may be precipitated by means of potass. Its properties have not hitherto been examined. It contains but a small proportion of oxygen.

2. The deutoxide of lead may be formed by dissolving the metal in nitric acid, and pouring potass into the solution. A yellow-coloured powder is obtained, which is the deutoxide of lead. This oxide is composed of 91 parts of lead, and 9 of oxygen. When lead is kept melted in an open vessel, its surface is soon covered with a grey-coloured pellicle. When this pellicle is removed, another succeeds it; and by continuing the heat, the whole of the lead may soon be converted into this substance. If these pellicles are heated and agitated for a short time in an open vessel, they assume the form of a greenish-grey powder. Mr. Proust has shewn that this powder is a mixture of deutoxide, and a portion of lead in the metallic state. It owes its green colour to the blue and yellow powders which are mixed in it. If we continue to expose this powder to heat for some time longer in an open vessel, it absorbs more oxygen, assumes a yellow colour, and is then known in commerce by the name of massicot. The reason of this change is obvious. The metallic portion of the powder gradually absorbs oxygen, and the whole of course is converted into deutoxide.

When thin plates of lead are exposed to the vapour of warm vinegar, they are gradually corroded, and converted into a heavy white powder, used as a paint, and called white lead. This powder used formerly to be considered as a peculiar oxide of lead; but it is now known that it is a compound of the deutoxide and carbonic acid.

3. If massicot ground to a fine powder is put into a furnace, and constantly stirred while the flame of the burning coals plays against its surface, it is in about 48 hours converted into a beautiful red powder, known by the name of minium, or red lead. This powder, which is likewise used as a paint, and for various other purposes, is the tritoxide or red oxide of lead.

4. If nitric acid, of the specific gravity 1.260, is poured upon the red-coloured oxide of lead, 185 parts of the oxide are dissolved; but 15 parts remain in the state of a black, or rather deep-brown, powder. This is the peroxide, or brown oxide of lead, first discovered by Scheele. The best method of preparing it is the following, which was pointed out by Proust, and afterwards still farther improved by Vauquelin. Put a quantity of red oxide of lead into a vessel partly filled with water, and make oxymuriatic acid gas pass into it. The oxide becomes deeper and deeper coloured, and is at last dissolved. Pour potass into the solution, and the brown oxide of lead precipitates. By this process 68 parts of brown oxide may be obtained for every 100 of red oxide employed. This oxide is composed of about 79 parts of lead and 21 of oxygen. It is of a brilliant flea-brown colour. When heated it emits oxygen gas, becomes yellow, and melts into a kind of glass. When rubbed along with sulphur in a mortar, it sets the sulphur on fire, and causes it to burn with a brilliant flame. When heated on burning coals the lead is reduced. All the oxides of lead are very easily converted into glass; and in that state they oxidize and combine with almost all the other metals except gold, platinum, and silver. This property renders lead exceedingly useful in separating gold and silver from the baser metals with which they happen to be contaminated. The gold or silver to be purified is melted along with lead, and kept for some time in that state in a flat cup, called a cupel, made of burnt bones, or the ashes of wood. The lead is gradually vitrified, and sinks into the cupel, carrying along with it all the metals which were mixed with the silver and gold, and leaving these metals on the cupel in a state of purity. This process is called cupellation. The lead employed is afterwards extracted from the cupels, and is known in commerce by the name of litharge. It is a half-vitrified substance, of a high red colour, and composed of scales. It is merely an oxide of lead more or less contaminated with the oxides of other metals. But the best litharge is made by oxidizing lead directly, and then increasing the heat till the oxide is fused. The more violent the fusing heat, the whiter is the litharge.

Lead has not yet been combined with carbon, nor hydrogen; but it combines readily with sulphur and phosphorus.

1. Sulphuret of lead may be formed either by stratifying its two component parts, and melting them in a crucible, or by dropping sulphur at intervals on melted lead. The sulphuret of lead is brittle, brilliant, of a deep blue-grey colour, and much less fusible than lead. These two substances are often found naturally combined; the compound is then called galena, and is usually crystallized in cubes. Sulphuret of lead is composed, according to the experiment of Wenzel, of 86.8 parts of lead and 13.2 of sulphur.

2. Phosphuret of lead may be formed by mixing together equal parts of filings of lead and phosphoric glass, and then fusing them in a crucible. It may be cut with a knife, but separates into plates when hammered. It is of a silver-white colour with a shade of blue, but it soon tarnishes when exposed to the air. This phosphuret may also be formed by dropping phosphorus into melted lead. It is composed of about 12 parts of phosphorus, and 88 of lead.

Lead does not combine with azotic gas. Muriatic acid gradually corrodes it, and converts it into a white-coloured oxide.

Lead is capable of combining with most of the metals.

1. Lead may be easily alloyed with gold by fusion. The colour of the gold is injured, and its ductility diminished. This alloy is of no use; but it is often formed in order to purify gold by cupellation.

2. Platinum and lead unite in a strong heat: the alloy is brittle, of a purplish colour, and soon changes on exposure to the air. Many experiments have been made with this alloy, in order, if possible, to purify platinum from other metals by cupellation, as is done successfully with silver and gold: but scarcely any of the experiments have succeeded; because platinum requires a much more violent heat to keep it in fusion than can be easily given.

3. Silver is often alloyed with lead in order to purify it by cupellation. This alloy is very fusible, much softer than silver, and has much less tenacity, elasticity, and sonorousness; its colour is nearly that of lead, and its specific gravity greater than the mean density of the metals alloyed.

4. Mercury amalgamates readily with lead in any proportion, either by triturating it with lead filings, or by pouring it upon melted

lead. The amalgam is white and brilliant, and when the quantity of lead is sufficient, assumes a solid form. It is capable of crystallizing. The crystals are composed of one part of lead and one and a half of mercury.

5. Copper and lead may be easily combined by fusion. When the lead exceeds, the alloy is of a grey colour, and ductile while cold, but brittle when hot. It is employed sometimes for the purpose of making printer's types for very large characters.

6. It was formerly supposed that lead does not combine with iron; but the experiments of Guyton Morveau have proved, that when the two metals are melted together, two distinct alloys are formed. At the bottom is found a button of lead containing a little iron; above is the iron combined with a small portion of lead.

7. Lead and tin may be combined in any proportion by fusion. This alloy is harder, and possesses much more tenacity, than tin. Muschenbroeck informs us that these qualities are a maximum when the alloy is composed of three parts of tin and one of lead. What is called in this country ley pewter is often scarcely any thing else than this alloy. Tin foil too almost always is a compound of tin and lead. This alloy, in the proportion of two parts of lead and one of tin, is more soluble than either of the metals separately. It is accordingly used by plumbers as a solder.

The affinities of lead and of its oxides are as follow:

Lead.	Oxide of Lead.
Gold,	Sulphuric acid,
Silver,	Saclactic,
Copper,	Oxalic,
Mercury,	Arsenic,
Bismuth,	Tartaric,
Tin,	Muriatic,
Antimony,	Phosphoric,
Platinum,	Sulphurous,
Arsenic,	Suberic,
Zinc,	Nitric,
Nickel,	Fluoric,
Iron,	Citric,
Sulphur.	Lactic,
	Acetic,
	Boracic,
	Prussic,
	Carbonic.

Lead, *ores of.* Ores of lead occur in great abundance in almost every part of the world. They are generally in veins; sometimes in siliceous rocks, sometimes in calcareous rocks.

The following table exhibits a view of the different states in which this mineral has hitherto been observed.

I. Sulphurets.	III. Salts.
1. Galena,	1. Carbonat,
2. Blue lead ore,	2. Muriocarbonat,
3. Black ore of lead.	3. Sulphat,
	4. Phosphat,
II. Oxides.	5. Molybdat,
1. Earthy ore of lead,	6. Arseniat?
2. Arseniated protoxide.	7. Arseniophosphat?
3. Arseniated peroxide,	8. Chromat.

Of these the first species is by far the most common. From it indeed almost the whole of the lead of commerce is extracted.

LEAF. See Botany.

Leaf-gold. See Aurum, Gold, Gilding, &c.

Leaf. See Architecture.

Leaf, in clocks and watches, an appellation given to the notches of their pinions. See Clockwork.

LEAGUE, a measure of length, containing more or less geometrical paces, according to the different usages and customs of countries. A league at sea, where it is chiefly used by us, being a land-measure mostly peculiar to the French and Germans, contains three thousand geometrical paces, or three English miles. The French league sometimes contains the same measure, and in some parts of France it consists of three thousand five hundred paces: the mean or common league consists of two thousand four hundred paces, and the little league of two thousand. The Spanish leagues are larger than the French, seventeen Spanish leagues making a degree, or twenty French leagues, or sixty-nine and a half English statute miles. The Dutch and German leagues contain each four geographical miles. The Persian leagues are pretty near of the same extent with the Spanish; that is, they are equal to four Italian miles, which is pretty near to what Herodotus calls the length of the Persian parasang, which contained thirty stadia, eight of which, according to Strabo, make a mile.

LEAK, among seamen, is a hole in the ship through which the water comes in. To spring a leak is said of a ship that begins to leak; to stop a leak, is to fill it with a plug wrapt in oakum and well tarred; or putting in a tarpaulin clout, to keep the water out; or nailing a piece of sheet-lead upon the place.

LEAKAGE, the state of a vessel that leaks, or lets water, or other liquid, ooze in or out. See the preceding article. Leakage, in commerce, is an allowance of 12 per cent. in the customs, allowed to importers of wines for the waste and damage it is supposed to have received in the passage; an allowance of two barrels in twenty-two is also made to the brewers of ale and beer, by the excise-office.

LEAP, in music. This word is properly applicable to any disjunct degree, but is generally used to signify a distance consisting of several intermediate intervals.

Leap-year. See Bissextile.

LEASE, a conveyance of lands, generally in consideration of rent or other annual recompence made for life, for years, or at will, but always for a shorter term than the lessor has in the premises, otherwise it partakes more of the nature of an assignment.

By the common law, all persons seized of an estate might grant leases for any period less than their interest lasted; but statutes have been since made, some to enlarge and some to restrict it. They are divided into enabling and restricting statutes; by the enabling stat. 32 Henry VIII. c. 28. a tenant in tail may make leases to ensure for twenty-one years or three lives to bind his issue in tail, but not those in remainder or reversion. Husbands seized in right of their wives may make leases for the same period, provided the wife join in it. All persons seized of an estate of fee-simple in right of their churches, except parsons or vicars, may bind their successors under certain restrictions. 1. The lease must be by indenture; 2. It must begin from the day of making; 3. All old leases must be surrendered or be within a year of expiring; 4. It must be for three lives or twenty-one years, not both; 5. It may be for a shorter term, but must not exceed twenty-one years; 6. It must be of lands and tenements most commonly let for twenty years past; 7. The most usual rent for that time must be reserved; 8. Such leases cannot be made without impeachment of waste. It was also specified that the lease must be of corporeal hereditaments, that the lessor might resort to them to distrain; but by stat. 5 Geo. III. c. 17, a lease of tithes or other incorporeal hereditaments may be granted, and the successor shall have his remedy by an action of debt.

From the disabling statutes, we find that all colleges, cathedrals, and other ecclesiastical or eleemosynary corporations, and all parsons and vicars, are restrained from making leases unless under the following regulations: 1. They must not exceed 3 lives or 21 years: 2. The accustomed rent must at least be reserved thereon: 3. Houses in corporations or market-towns may be let for 40 years, provided they are not the mansion-houses of the lessors, or have not more than 10 acres of ground belonging to them; and provided the lessee agrees to keep them in repair, and they may be aliened in fee-simple for lands of equal value in recompence: 4. If there is an old lease which has more than 3 years to run, no new lease shall be made: 5. No lease shall be made without impeachment of waste: 6. All bonds and covenants tending to frustrate the provisions of the statutes of 13 and 18 Eliz. shall be void.

Two observations seem to present themselves concerning these statutes: 1. That they do not enable any persons to make such leases as they are by common law restrained from making; therefore, a parson or vicar, though he is restrained from making longer leases than for 21 years or 3 lives, even with the consent of the patron or ordinary, yet is not enabled to make any lease at all, to bind his successor without such consent. 2. Though leases contrary to these acts are void, yet they are good against the lessor during his life, if he is a sole corporation; and if it is an aggregate corporation, as long as the head lives: for the act was intended for the benefit of the successor alone, and it is a maxim of law that no man shall take advantage of his own wrong. With regard to college leases, one-third of the old rent must be reserved in wheat or malt, reserving a quarter of wheat for every 6*s.* 8*d.* and a quarter of malt for every 5*s.*; or the lessees must pay for the same, at the price of the market nearest the respective colleges on the market-day before the rent is due.

There are further restraining statutes which direct that if any beneficed clergyman is absent from his benefice above 80 days in the year, all leases and agreements made by him of the profits of his cure shall be void, except in the case of licensed pluralists; who are allowed to demise the living to the curate, if he is not absent more than 40 days in the year. See 13 Eliz. c. 20. 14 Eliz. c. 11. 18 Eliz. c. 11, and 43 Eliz. c. 9.

All leases except such as do not exceed

3 years from the making, whereupon the reserved rent must be at least two-thirds of the improved value, must be in writing, though no particular form of words is necessary to constitute a good lease.

They must be made to natural-born subjects of this realm, or such as have been naturalized, or to denizens, for all leases made to aliens shall be void; and there is even a statute in force, 32 Hen. VIII. c. 16, which imposes a penalty of 5*l*. on the lessor and lessee. It has however been held that an alien merchant may take a house for his own residence, but it shall not go to his executors; the reasons for these laws are evidently to prevent foreigners getting too firm a footing in the kingdom.

Lease and *release* is a conveyance which since the stat. 27 Hen. VIII. c. 10, commonly called the statute of uses, has taken place of the deed of feoffment, as it supplies the need of livery and seisin. It is made thus: A lease or bargain and sale for one year, from the tenant to the lessee, is first prepared, whereby the lessee becomes actually possessed of the lands, then by the above-mentioned statute the lessee is enabled to take a grant of the lands intended to be conveyed to him and his heirs for ever; accordingly a release is made, reciting the lease and declaring the uses. In the lease, a peppercorn is a good consideration to make the lessee capable of receiving a release. This mode of conveyance is become so usual, that it merits peculiar attention. See this matter very ably discussed by the annotator of the latter part of Coke's Commentaries, p. 271, No. I.

LEASES, *value of*. The purchaser of a lease may be considered as the purchaser of an annuity equal to the rack-rent of the estate; and the same principles, from which are deduced the present value of annuities to continue during any given term, will apply to the value of leases. The sum paid down for the grant of a lease is so much money paid in advance for the annual rents, as they may become due; or, it may be considered as a sum which put out to interest, will enable the lessor to repay himself the rack-rent of the estate, or the yearly value of his interest therein, during the given term; therefore no more money should be demanded by the lessor, for the grant of the lease, than will enable him to do this at a given rate of interest. In order to find what this sum should be it would be necessary to ascertain separately the present value of each annual rent, or the sum which, put out to interest at the given rate, will enable the landlord to repay himself the several yearly rents as they become due. Thus, if a person has 100*l*. due to him a twelvemonth hence, and he wishes to have the value of the same advanced immediately, the sum that ought to be given as an equivalent thereto, allowing 5 per cent. interest, is 95*l*. 4*s*. 9¼*d*.; for this is the sum which, put out to interest at the rate of 5 per cent., will, at the end of the year, amount to 100*l*. So also, if a person has 100*l*. due to him at the end of two years, and he wishes to have the value advanced immediately, the sum that ought to be given as an equivalent thereto, is 90*l*. 14*s*. ¾*d*. for this is the sum which put out at the same rate of interest, will, at the end of two years amount to 100*l*. In the same manner, if a person has 100*l*. due to him, at the end of three years, and he wishes to have the value of the same immediately, the sum that ought to be given as an equivalent thereto, is 86*l*. 7*s*. 8*d*. for this is the sum which put out at the same rate of interest, will, at the end of three years, amount to 100*l*. And if these three values are added together, they amount to 272*l*. 6*s*. 6*d*. which is the sum that ought to be paid down for the lease of an estate for three years, of the annual rent of 100*l*. Had the rate of interest been 6 per cent. or any higher rate, the answer would have come out less than the value above given; or, had it been 4 per cent. or any lower rate, the answer would have come out more than such value; whence it is obvious, that, in purchases of this kind, we ought previously to determine the rate of interest at which we are disposed to lay out our money. The value of leases at 5 per cent. compound interest, may be found from table 2, article Annuities; but as most persons in purchasing leases expect to make somewhat more than 5 per cent. interest of their money, the following table is more applicable to this purpose.

TABLE,

Shewing the Number of Years Purchase that ought to be given for a Lease, for any Number of Years not exceeding 100, at 6, 7, and 8 per Cent. Interest.

Years	6 per Cent.	7 per Cent.	8 per Cent.

100	16.6175	14.2692	12.4943

In order to find the value of a lease, it is first necessary to ascertain the true rack-rent of the estate, or the annual value that it may be justly estimated to be worth; otherwise it will be impossible to determine, with any degree of accuracy, the real sum which ought to be given for the purchase of the same. On this point difficulties will sometimes arise; for, the value of an estate depending very often on some real or supposed advantages, or on some local or personal recommendations, will, in many instances, occasion a difference of opinion; and in most cases, be a matter of some uncertainty. However, when all these circumstances have been taken into consideration, some annual rent equivalent thereto must be assumed, and when this is settled the value of the lease will be easily found; thus, if an estate is worth 150*l*. yearly rent, the value of a lease thereof for sixty-nine years, allowing the purchaser 6 per cent interest for his money, is 16,3676 (the number in the table) multiplied by 150, or 2455*l*. 2*s*. 9*d*. In many instances, the rent of the estate intended to be leased is charged with some annual expence, such as a reserved or quit rent, the payment of an annuity, taxes, and the like; in such cases the number of years purchase found in the table ought to be multiplied by the difference only between such annual expence and the whole estimated rent of the estate; thus if a person possesses an unexpired term of sixty years in a lease, for which he pays 100*l*. per annum rent, but which is now worth 150*l*. per annum, the gross sum which he ought to receive for the grant of such lease, will be equal to the present value of 50*l*. per annum, for the given term; or 16,1614 (the number in the table corresponding with 60 years, at 6 per cent.) multiplied by 50, which gives 808*l*. 1*s*. 4*d*.

In order to find the annual rent corresponding to any given sum paid for a lease, divide the sum paid by the number of years purchase that are found against the given term in the table, and the quotient will be the annual rent required. Example: A person has given 1000*l*. for the lease of an estate for 16 years, what annual rent is equivalent thereto in order to allow the purchaser 7 per cent. interest for his money? In the table against 16 years, and under 7 per cent. we shall find the number of years purchase to be 9.4466: therefore 1000 divided by 9.4466 gives 105*l*. 17*s*. for the annual rent required.

The values in the table are calculated on the supposition that the payments of the several rents of the estate are made yearly; if however the payments are made half-yearly or quarterly, and the purchaser can put out his money at the same rate, so as to receive his interest half-yearly or quarterly, which may commonly be done; the values will, in such cases, be somewhat more than those given in the table. The difference, however, is not very great, but if the exact value is required, it may in many cases be obtained by attending to the following remarks, viz. that "the value of a lease, the rent of which is payable half-yearly, is equal to half the value of the same lease payable yearly, calculated at half the given rate of interest, and to continue double the number of years; and that the value of a lease the rent of which is payable quarterly, is equal to one quarter the value of the same lease payable yearly, calculated at a quarter of the given rate of interest, and to continue four times the number of years."

It frequently happens that a long lease is not to be entered on or enjoyed till after the expiration of a short lease, or till the end of a given number of years; in such cases, deduct the value of the short lease, or the value set against the given number of years in the table, from the value of the longer lease, and the difference will give the true present value of the longer lease. Example: What sum ought to be given for the remainder of the lease of an estate for 56 years, after the next seven years, allowing the purchaser 6 per cent. interest for his money, the clear rent being reckoned at 70*l*. per annum? In the table against 56 years, and under 6 per cent. we find 16.0288, and in the same column against 7 years we find 5.5823; the latter value subtracted from the former leaves 10.4465, which multiplied by 70 gives 731.255 or 731*l*. 5*s*. 1*d*. for the sum required.

Leases are frequently granted during a life, or for a specified term of years subject to termination, if a given life or lives should fail or become extinct within such term; sometimes they depend on the longest of two or three lives, with liberty on the failure of one or more of the lives to nominate others on payment of a fine. The values of such leases are given in a very useful collection of tables for the purchasing and renewing of leases by F. Baily, and may in most cases be found from the tables inserted under the article LIFE ANNUITIES.

LEATHER. See CUTIS, and TANNING.

LEAVEN. See FERMENTATION.

LECHŒA, a genus of the triandria trigynia class and order. The calyx is three-leaved: petals, three-linear; capsules, three-celled, three-valved, seeds solitary. There are three species, herbaceous plants of America and China.

LECYTHIS, a genus of the polyandria monogynia class and order. The calyx is six-leaved; corolla, six-petalled; nectarine, lingulate, staminiferous; peric. circumcised, many-seeded. There are six species, trees or shrubs of Guiana.

LEDGER, the principal book wherein merchants enter their accounts. See BOOK-KEEPING.

LEDGES, in a ship, are small pieces of timber lying athwart from the waste-trees to the roof-trees: they serve to bear up the gratings or nettings over the half-deck. See SHIP-BUILDING.

LEDUM, marsh cistus, or wild rosemary; a genus of the monogynia order, in the decandria class of plants; and in the natural method ranking under the 18th order, bicornes. The calyx is quinquefid; the corolla plain and quinquepartite; the capsule quinquelocular, and opening at the base. There are three species: The palustre with very narrow leaves, grows naturally upon bogs and mosses in many parts of Yorkshire, Cheshire, and Lancashire. The flowers are produced in small clusters at the end of the branches, and are shaped like those of the strawberry-tree, but spread open wider at top. These are of a reddish colour, and in the natural places of their growth are succeeded by seed-vessels filled with small seeds which ripen in autumn.

LEE, in the sea-language, a word of various significations, though it is generally understood to mean the part opposite to the wind. Thus lee-shore, is that shore against which the wind blows. Lee-latch, or have a care of the lee-latch, is, take care that the ship don't go to the leeward, or too near the shore; a lee the helm, put it to the leeward side of the ship; to lie by the lee, or to come up to the lee, is to bring the ship so, that all her sails may lie flat against her masts and shrouds, and that the wind may come right upon her broadside.

LEE-FANG, is a rope reeved into the cringles of the courses, to hale in the bottom of the sail, that the bonnets may be laced on, or the sail taken in.

LEE-WAY, is the angle that the rhumb-line upon which the ship endeavours to sail, makes with the rhumb upon which she really sails. See NAVIGATION.

LEEA, a genus of the class and order pentandria monogynia. The calyx is one-petalled; nect. on the side of the corolla, upright, five-cleft; berry, five-seeded. There are three species, trees of the East Indies.

LEECH. See HIRUDO.

LEEK. See ALLIUM.

LEERSIA, a genus of the class and order triandria digynia. Calyx none; glume, two-valved, closed. There are three species, grasses of America.

LEET, a little court held within a manor, and called the king's court, on account that its authority to punish offences originally belonged to the crown, whence it is derived to inferior persons. See COURT.

LEETCH-LINES, small ropes made fast to the leetch of the topsails, to which they belong, and reeved into a block at the yard close by the topsail-ties. They serve to hale in the leetch of the sail when the topsails are to be taken in.

LEGACY, a bequest of a sum of money, or any personal effects of a testator: and these are to be paid by his representative, after all the debts of the deceased are discharged, as far as the assets will extend.

All the goods and chattels of the deceased, are by law vested in the representative, who is bound to see whether there be left a sufficient fund to pay the debts of the testator, and if it should prove inadequate, the pecuniary legacies must proportionately abate; a specific legacy, however, is not to abate unless there be insufficient without it.

If the legatee die before the testator, such will in general be termed a lapsed legacy, and fall into the general fund; where however, from the general import of the will, it can be collected that the testator intended such a vested legacy, it will in such case go to the representative of the deceased legatee.

If a bequest be made to a person, if or when he attains a certain age, the legacy will be lapsed, if he die before he attain that age; but if such legacy may be made payable at that age, and the legatee die before that age, such legacy will be vested in his representative.

If in the latter case, the testator devise interest to be paid in the mean time, it will nevertheless be a vested legacy.

Where a legacy is bequeathed over to another, in case the first legatee die under a certain age, or the like, the legacy will be payable immediately on the death of the first legatee; and though such legacy be not bequeathed over, yet if it carry interest, the representative will become immediately entitled to it.

In case of a vested legacy due immediately, and charged on land, or money in the funds which yields an immediate profit, interest shall be payable from the death of the testator; but if it be charged on the personal estate only of the testator, which cannot be collected in, it will carry interest only from the end of the year after the death of the testator.

If a bequest be for necessaries, and of small amount, the executor will be justified in advancing a part of the principal; but this should be done under very particular circumspection, as the executor may be compelled to pay the full legacy on the infant's attaining his majority, without deducting the sum previously advanced.

When all the debts and particular legacies are discharged, the residue or surplus must be paid to the residuary legatee, if any be so appointed in the will; but if there be none appointed or intended, it will go to the executor or next of kin.

When this residue does not go to the executor, it is to be distributed among the intestate's next of kin, according to the statute of distributions; except the same is otherwise disposable by particular customs, as those of London, York, &c. See EXECUTOR.

LEGATE, a cardinal or bishop, whom the pope sends as his ambassador to sovereign princes.

There are three kinds of legates, viz. legates a latere, legates de latere, and legates by office, or legati nati; of these the most considerable are the legates a latere, the next are the legates de latere.

Legates by office are those who have not any particular legation given them, but who by virtue of their dignity and rank in the church, become legates; such are the archbishops of Rheims and Arles; but the authority of these legates is much inferior to that of the legates a latere.

LEGATUS, in Roman antiquity, a military officer who commanded as deputy of the chief general.

LEGER-LINE, in music, one added to the staff of five lines, when the ascending or descending notes run very high or low.

LEGION, in Roman antiquity, a body of foot which consisted of ten cohorts.

The exact number contained in a legion, was fixed by Romulus at three thousand; though Plutarch assures us, that after the reception of the Sabines into Rome, he increased it to six thousand. The common number afterwards, in the first times of the free state, was four thousand; but in the war with Hannibal, it arose to five thousand, and after this it is probable that it sunk again to four thousand, or four thousand two hundred, which was the number in the time of Polybius.

LEGNOTIS, a genus of the class and order polyandria monogynia. The calyx is five-cleft; pet. 5; caps. 3-celled. There are two species, trees of Jamaica and Guiana.

LEMMA, in mathematics, a proposition which serves previously to prepare the way for the more easy apprehension of the demonstration of some theorem, or construction of some problem.

LEMNA, a genus of the monœcia diandria class and order. The male cal. is one-leaved; cor. none: female, cal. one-leaved; cor. none; style one; caps. one-celled. There are six species, known by the name of duck-weed, or duck-meat.

LEMNISEA, a genus of the class and order polyandria monogynia. The cal. is 5-toothed; cor. 6-petalled, recurved; nect. cap-shaped, girding; the germ. per. 5-celled, seeds solitary. There is 1 species, a tree of Guiana.

LEMON. See CITRUS.

LEMON, *salt of*. See OXALAT *of potass*.

LEMUR, MACAUCO, a genus of quadrupeds of the order primates: the generic character is, front-teeth in the upper jaw, four; the intermediate ones remote: in the lower jaw, six; longer, stretched forwards, compressed, parallel, approximated. Canine-teeth solitary, approximated; grinders several, sublobated; the foremost somewhat longer and sharper.

The genus lemur or macauco consists of animals approaching to monkeys in the form of their feet, which, in most species, are furnished with flat nails; but differing in their manners, and void of that mischievous and petulant disposition which so much distinguishes the monkey tribe from other quadrupeds.

In this, as in the former genus, we meet with some species without a tail, while others have that part extremely long. Of the tailless species the most remarkable is the

1. Lemur tardigradus, slow lemur. It is about the size of a small cat, measuring sixteen inches in length; its colour is an elegant pale-brown or mouse-colour; the face flattish; the nose inclining to a sharpened form; the eyes yellow-brown, large, and extremely protuberant, so as to appear in the living animal like perfect hemispheres. They are surrounded by a circle of dark brown, which also runs down the back of the animal. This species is very slow in its motions, and from this circumstance has actually been ranked by some naturalists among the sloths; though in no other respect resembling them. It is a nocturnal animal, and sleeps, or at least lies motionless, during the greatest part of the day; its voice is shrill and plaintive.

2. Lemur indri. This is a very large species; it is entirely of a black colour, except on the face, which is greyish; a greyish cast also prevails towards the lower part of the abdomen, and the rump is white. The face is of a lengthened or dog-like form; the ears shortish and slightly tufted; the hair or fur is silky and thick, and in some parts of a curly or crisped appearance: it is the largest animal of this genus, and is said by Mons. Sonnerat, its first describer, to be three feet and a half high; it is said to be a gentle and docile animal, and to be trained, when taken young, for chace, in the manner of a dog. Its voice resembles the crying of an infant. It is a native of Madagascar, where it is known by the name of Indri, which is said to signify the man of the wood. The nails in this species are flat, but pointed at the ends; and there is no appearance of a tail.

3. Lemur macaco, ruffed lemur. This is the species described by the count de Buffon, under the name of the vari, its colours often consisting of a patched distribution of black and white; though its real or natural colour is supposed to be entirely black. In size it exceeds the mongos, or brown lemur. It is said to be a fierce and almost untameable animal: it inhabits the woods of Madagascar and some of the Indian islands; and is said to exert a voice so loud and powerful as to strike astonishment into those who hear it, resembling, in this respect, the howling monkey or S. Belzebub, which fills the woods of Brasil and Guiana with its dreadful cries. When in a state of captivity, however, it seems to become as gentle as some others of this genus.

The astonishing strength of voice in this animal, depends, according to the count de Buffon, on the peculiar structure of the larynx, which widens, immediately after its divarication, into a large cavity before entering the lungs.

4. Lemur tarsier. This animal is distinguished by the great length of its hind legs. Its general length from the nose to the tail is almost six inches; and from the nose to the hind toes eleven inches and a half; the tail nine inches and a half. The face is sharp or pointed; the eyes very large and full; the ears upright, broad, naked, and rounded. Between the ears on the top of the head is a tuft of long hairs. The colour of this species is grey-brown or mouse-colour, paler beneath. It is a native of Amboina and some other East Indian islands.

5. Lemur psilodactylus, long-fingered lemur. This highly singular species has so much the general appearance of a squirrel, that it has been referred to that genus both by Mr. Pennant in the last edition of his History of Quadrupeds, and by Gmelin in his enlarged edition of the Systema Naturæ of Linnæus. The account, however, given by Mons. Sonnerat, its first describer, seems to prove it a species of lemur. It measures from fourteen to eighteen inches from the nose to the tail, which is about the same length. The general colour of the animal is a pale ferruginous-brown, mixed with black and grey; on the head, round the eyes, and on the upper parts of the body, the ferruginous brown prevails, with a blackish cast on the back and limbs; the tail is entirely black; the sides of the head, the neck, the lower jaw, and the belly, are greyish. There are also a kind of woolly hairs of this colour, and of two or three inches in length, scattered over the whole body; the thighs and legs have a reddish cast; the black prevails on the feet, which are covered with short hairs of that colour; the head is shaped like that of a squirrel; and there are two cutting-teeth in front of each jaw; the ears are large, round, and naked, resembling those of a bat, and of a black colour. The feet are long, and somewhat resemble those of the Tarsier; the thumbs or interior toes of the hind feet are short, and furnished with flat round nails, as in the macaucos; but the principal character of the animal consists in the extraordinary structure of the fore-feet, which have the two middle toes of an uncommon length, most extremely thin, and perfectly naked, except at their base; all the claws on the fore-feet are sharp and crooked. It is a timid animal, and can scarcely see distinctly by day; and its eyes, which are of an ochre colour, resemble those of an owl.

This species is a native of Madagascar, where it inhabits woods; it is extremely rare, and is supposed to feed on fruits, insects, &c.: it is fond of warmth, and has the same slow motion as the lemur tardigradus. Its native name is aye-aye, which is said to be taken from its natural voice or cry, which resembles a feeble scream.

6. Lemur volans, flying macauco, inhabits Guzurat, the Philippine and Molucca isles, is gregarious, nocturnal, feeds on fruits. See Plate Nat. Hist. fig. 249.

LENS, in dioptrics, properly signifies a small roundish glass, of the figure of a lentil; but is extended to any optic glass, not very thick, which either collects the rays of light into a point, in their passage through it, or disperses them further apart, according to the laws of refraction. See OPTICS.

LEO, in astronomy, one of the twelve signs of the zodiac, the fifth in order; containing, according to Ptolemy, thirty-two stars; according to Tycho, thirty-seven; and in the Britannic catalogue, there are no less than ninety-four. The star called the lion's-heart, cor leonis, regulus, and basilicus, is a fixed star of the first magnitude.

LEONTICE, *lion's leaf*; a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 24th order, corydales. The corolla is hexapetalous; the nectarium hexaphyllous, standing on the heels of the corolla, with its limb patent; the calyx hexaphyllous, and deciduous. There are three species, natives of the southern parts of Europe, two of which are sometimes cultivated in this country. These are, 1. The chrysogonum with winged leaves; and 2. The leontopetalum with decompounded leaves. But those plants are natives of the Archipelago islands, and also grow in the corn-fields about Aleppo in Syria, where they flower soon after Christmas.

LEONTODON, *dandelion*: a genus of the polygamia æqualis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the calyx imbricated, with the scales somewhat loose; the pappus feathery. There are four species, of which the only remarkable one is the taraxacum, or common dandelion, found on the road sides, in pastures, and on the banks of ditches. Early in the spring, the leaves whilst yet white and hardly unfolded are an excellent ingredient in sallads. The French eat the roots and tender leaves with bread and butter. Children that eat it in the evening experience its diuretic effects in the night, which is the reason for its vulgar appellation. When a swarm of locusts had destroyed the harvest in the island of Minorca, many of the inhabitants subsisted upon this plant. The expressed juice has been given to the quantity of four ounces three or four times a day; and Boerhaave had a great opinion of the utility of this and other lactescent plants in visceral obstructions. Goats eat it; swine devour it greedily; sheep and cows are not fond of it, and horses refuse it. Small birds are fond of the seeds.

LEONURUS, *lion's tail*; a genus of the gymnospermia order, in the didynamia class of plants: and in the natural method ranking under the 42nd order, verticillatæ. The antheræ are powdered with shining points, or small elevated globular particles.

The species are: 1. The Africana, with spear-shaped leaves, a native of Ethiopia. The flowers are produced in whorls, each of the branches having two or three of these whorls towards their ends. They are of the lip-kind, shaped somewhat like those of the dead-nettle; but are much longer, and covered with short hairs. They are of a golden scarlet colour, so make a fine appearance. 2. The nepetæfolia, with oval leaves, a native of the Cape of Good Hope. The flowers come out in whorls like those of the former sort; but are not so long nor so deep-coloured. They appear at the same season with the first, and continue as long in beauty. There are three other species, but the above are the most remarkable.

Both sorts are propagated by cuttings, which should be exposed to the air long enough to harden the shoots, and planted in the beginning of July, after which they will take root very freely. They should be planted in a loamy border to an eastern aspect: and if they are covered closely with a bell or hand glass to exclude the air, and shaded from the sun, it will forward their putting forth roots. As soon as they have taken good root, they should be taken up and planted each in a separate pot filled with soft loamy earth, and placed in the shade till they have taken new root. In October they must be removed into the greenhouse.

LEOPARD. See FELIS.

LEOPARD'S *bane*. See DORONICUM.

LEPAS, a genus of vermes testacea: the animal a triton, shell affixed at the base, and consisting of many unequal erect valves. The lepas antifera, or duck-bernacle, has the shell compressed, five-valved, smooth, seated on a bernacle. It inhabits most seas, and is found fixed in clusters to the bottom of vessels, and old pieces of floating timber, generally whitish with a blue cast, the margins of the valves yellow; sometimes marked with black; peduncle long, coriaceous, black, and much wrinkled towards the shell, and growing paler and pellucid towards the base. See Plate Nat. Hist. fig. 248.

LEPIDIUM, DITTANDER, or *pepperwort*: a genus of the siliculosæ order, in the tetradynamia class of plants; and in the natural method ranking under the 39th order, siliquosæ. The silicula is emarginated, cordated, and polyspermous, with the valves carinated contrary or broader than the partition. There are 23 species, of which the only remarkable one is the latifolium or common dittander. This is a native of many parts of England. The whole plant has a hot biting taste like pepper; and the leaves have been often used by the country-people to give a relish to their viands instead of that spice, whence the plant has got the appellation of poor man's pepper. It is reckoned an antiscorbutic, and was formerly used instead of the horseradish scurvy-grass.

LEPIDOLITE. See LILALITE.

LEPIDOPTERA, in zoology, an order of insects with four wings, which are covered with imbricated squamulæ: add to this that the mouth is commonly spiral.

Under this order are comprehended the phalæna, sphinx, and papilio genera.

LEPISMA, the name of a genus of insects of the order aptera. The generic character is, legs six, formed for running; mouth with two setaceous and two headed feelers; body imbricated with two minute scales; tail furnished with extended bristles.

The Linnæan genus lepisma is far from extensive, those enumerated by Linnæus himself in the twelfth edition of the Systema Naturæ amounting to no more than three species.

Of these the chief is the lepisma saccharina (See Plate Nat. Hist. fig. 245), frequently called in our own country, from its peculiar colour and tapering form, by the name of the wood-fish. This is an insect of great elegance. Its general length, exclusive of the caudal bristles, is about half an inch, and its colour a bright silvery grey, resembling that of pearls; this colour is owing to a covering of extremely minute oval scales, which are semitransparent, very easily detached from the animal by a slight touch; the head and thorax together form a rounded outline, the remainder of the body gradually lessening to the tail, which terminates in three long bristles, of similar appearance with the antennæ. The motions of this animal are remarkably quick, and it is often observed among various domestic articles, particularly sugar. It also occurs not unfrequently among old books and papers, which it is supposed often to injure. It is said to be originally an American animal, and to have been imported into Europe among sugars, &c. Dr. Browne, in his History of Jamaica, represents it as "extremely destructive to books and all manner of woollen clothes."

Lepisma polypus Lin. is of a dusky or brownish cast, and has a springing or leaping motion when disturbed. It is found about the sea-coast of many northern regions, under stones, &c.

LEPROSY. See MEDICINE.

LEPTURA, the name of a genus of insects of the order coleoptera: the generic character is, antennæ setaceous; wing-sheaths attenuated towards the tip; thorax subcylindric. The genus leptura, greatly allied to that of cerambyx, contains several species of considerable beauty; among which may be reckoned the leptura arcuata, of a black colour, with the wing-sheaths marked by transverse, yellow, lunated bands pointing backwards; it is found in woods during the summer months, and generally measures about three quarters of an inch in length.

Leptura arietis is of nearly similar appearance, but the second band of the wing-sheaths is directed forwards; both the above insects are by some referred to the genus cerambyx.

Leptura aquatica is so named from its being particularly found in the neighbourhood of waters, frequenting the plants which grow near the water's edge. It is about half an inch in length, and of a golden green-colour, sometimes varying into copper-colour, purple, or blue, and is distinguished by having a tooth or process on the thighs of the hind legs.

The larvæ of the lepturæ in general are probably allied to those of the cerambyces, but they are at present little known.

LEPUS, hare, a genus of quadrupeds of the order glires. The generic character is, front-teeth two both above and below, the upper pair duplicate; two small interior ones standing behind the exterior. This genus, when considered with anatomical exactness, exhibits particularities of structure, deviating somewhat from that of the glires, and making an indistinct approach to the pecora or ruminants. It has even been supposed that the common hare actually ruminates; an opinion owing not only to the peculiar motions of the mouth, which present an obscure appearance of rumination, but to the structure of the stomach, which is marked into two regions by a particular fold or ridge. Other singularities relative to internal formation may be met with in the works of comparative anatomists. The most remarkable species are,

1. Lepus timidus, common hare. The hare is an animal so familiarly known as to supersede the necessity of any very minute description. It is a native not only of every part of Europe, but of almost every part of the old continent. It may perhaps be doubted whether it is an aboriginal native of any part of America.

The favourite residence of the hare is in rich and somewhat dry and flat grounds, and it is rarely discovered in very hilly or mountainous situations. It feeds principally by night, and remains concealed during the day in its form, beneath some bush, or slight shelter.

The swiftness of this animal is proverbial, and on account of the conformation of its legs, the hinder of which are longer than the fore, it is observed to run to most advantage on slightly ascending ground.

The hare is a very prolific animal, generally producing three or four young at a time, and breeding several times in a year. The young require the assistance of the parent but for a short time, and in about three weeks are able to provide for themselves; they do not remove to any great distance from each other, but continue in the same neighbourhood for a considerable time. The hare feeds on various vegetables, but is observed to prefer those of a milky and succulent quality. It also occasionally feeds on the bark of trees, as well as on the young shoots of various shrubs, &c.

The nature of the soil in which the hare resides and feeds, is observed to influence in a considerable degree the colour and constitution of the animal. Those which feed in elevated situations are larger and darker than those which reside in the plains.

The hare is an animal proverbially timid, and flies, if disturbed when feeding by the slightest alarm; but when seated in its form, will allow itself to be approached so near as to be reached by a stick; seeming to be fascinated by fear, and instead of endeavouring to fly, continuing to squat immoveable, with its eyes fixed on its enemy. It is necessary, however, in order to conduct this manœuvre, to approach in a gradual and circling manner.

The hare, though so nearly allied to the rabbit as to make the general descriptive distinction not very easy, is yet of different habits and propensities, and never associates with the latter animal. If taken very young, the hare may be successfully tamed, and in that state shews a considerable degree of attachment to its benefactors, though it continues shy to those whose presence it has not been accustomed to. Mr. White, in his History of Selbourne, relates an instance which happened in that village, of a young leveret suckled and nursed by a cat, which received it very early under her protection, and continued to guard it with maternal solicitude till it was grown to a considerable size.

A most singular variety of this animal is sometimes found, which is furnished with rough and slightly branched horns, bearing a considerable resemblance to those of a roebuck. This particularity, as strange as it is uncommon, seems to imply a kind of indistinct approach in this animal to the order pecora.

The hare is a short-lived animal, and is supposed rarely to exceed the term of seven or eight years.

It may be proper to add, that in very severe winters, and especially in those of the more northern regions, the hare becomes entirely white, in which state it is liable to be mistaken for the following species.

2. Lepus variabilis, varying hare. This species is an inhabitant of the loftiest alpine tracts in the northern regions of the globe; occurring in Norway, Lapland, Russia, Siberia, and Kamtschatka; and in our own island on the alps of Scotland. The same species is also found to extend to America, appearing in some parts of Canada. In its general appearance it bears an extreme resemblance to the common hare, but is of smaller size, and has shorter ears and more slender legs. Its colour in summer is a tawny grey; in winter entirely white, except the tips of the ears, which are black; the soles of the feet are also black, but are very thickly covered with a yellowish fur. This animal is observed to confine itself altogether to elevated situations, and never to descend into the plains, or to mix with the common hare. The change of colour commences in the month of September, and the grey or summer coat reappears in April; but in the very severe climate of Siberia it continues white all the year round. It has been sometimes found entirely coal-black, a variety which is also known to take place occasionally in the common hare. The varying hare sometimes migrates in order to obtain food in severe seasons. Troops of five or six hundred have been seen to quit in this manner the frozen hills of Siberia, and to descend into the plains and woody districts, from which they again return in spring to the mountains.

3. Lepus Americanus, American hare. This animal is not much superior in size to a rabbit, measuring about eighteen inches. Its colour nearly resembles that of the common hare, to which it seems much allied: but the fore legs are shorter, and the hind ones longer in proportion. The belly is white; the tail black above and white beneath; the ears tipped with grey, and the legs of a pale-ferruginous colour. It is said to inhabit all parts of North America; and in the more temperate regions retains its colour all the year round, but in the colder parts becomes white in winter, when the fur grows extremely long and silvery; the edges of the ears alone retaining their former colour. It is said to be extremely common at Hudson's Bay, where it is considered as a highly useful article of food. It breeds once or twice a year, producing from five to seven at a time. It is not of a migratory nature, but always continues to haunt the same places, taking occasional refuge under the roots of trees, or in the hollows near their roots.

4. Lepus cuniculus, rabbit. The rabbit bears a very strong general resemblance to the hare, but is considerably smaller, and its fore feet are furnished with sharper and longer claws in proportion; thus enabling it to burrow in the ground, and to form convenient retreats, in which it conceals by day, and like the hare, comes out chiefly by night and during the early part of the morning to feed. Its colour, in the wild state, is a dusky brown, paler or whitish on the under parts, and the tail is black above and white below. In a domestic state the animal varies into black, black-and-white, silver-grey, perfectly white, &c.

The rabbit is a native of most of the temperate and warmer parts of the old continent, but is not found in the northern regions, and is not originally a native of Britain, but was introduced from other countries. Its general residence is in dry, chalky, or gravelly soils, in which it can conveniently burrow. It is so prolific an animal that it has been known to breed seven times in a year, and to produce no less than eight young each time. It is therefore not surprising, that in some countries it has been considered as a kind of calamity, and that various arts of extirpation have been practised against it.

5. Lepus viscaccia. This species is said to have the general appearance of a rabbit, but has a long bushy and bristly tail, like that of a fox, which the animal also resembles in colour; the fur on all parts, except the tail, is soft, and is used by the Peruvians in the manufacture of hats; it was also used by the ancient Peruvians for the fabric of garments, worn only by persons of distinction. In its manners this animal resembles the rabbit, burrowing under ground, and forming a double mansion, in the upper of which it deposits its provisions, and sleeps in the other. It appears chiefly by night, and is said to defend itself when attacked by striking with its tail.

6. Lepus alpinus, alpine hare. This is a very different species from the alpine hare described by Mr. Pennant in the British Zoology, which is no other than the varying hare. The alpine hare is a far smaller animal, scarcely exceeding a guinea-pig (cavia cobaya) in size, and measuring only nine inches in length. Its colour is a bright ferruginous grey, paler beneath; the head is long, and the ears short, broad, and rounded. See Plate Nat. Hist. fig. 246. It appears to have been first described by Dr. Pallas, who informs us that it is a native of the Altaic mountains, and extends to the Lake Baikal, and even to Kamtschatka, inhabiting rough woody tracts amidst rocks and cataracts, and forming burrows beneath the rocks, or inhabiting the natural fissures, and dwelling sometimes singly, and sometimes two or three together. In their manners they greatly resemble some of the marmots or hamsters; preparing, during the autumn, a plentiful assortment of the finest herbs and grasses, which they collect in company, and after drying with great care in the sun, dispose into heaps of very considerable size, for their winter support; and which may always be distinguished, even through the deep snow, having the appearance of so many hay-ricks in miniature, and being often several feet in height and breadth. The alpine hare varies in size according to the different regions in which it is found, being largest about the Altaic mountains, and smaller about Lake Baikal, &c.

7. Lepus ogotona, ogotona hare. This animal, says Dr. Pallas, is called by the Mongolians by the name of ogotona, and is an inhabitant of rocky mountains, or sandy plains, burrowing under the soil, or concealing itself under heaps of stones, and forming a soft nest at no great depth from the surface. It wanders about chiefly by night, and sometimes appears by day, especially in cloudy weather. In autumn it collects heaps of various vegetables for its winter food, in the same manner as the alpine hare before described, disposing them into neat hemispherical heaps of about a foot in diameter. These heaps are prepared in the month of September, and are entirely consumed by the end of winter.

The ogotona hare is about six inches or somewhat more in length, and is of a pale-brown colour above, and white beneath; on the nose is a yellowish spot, and the outsides of the limbs and space about the rump are of the same colour. It is entirely destitute of a tail. See Plate Nat. Hist. fig. 247.

8. Lepus pusillus, calling hare. In its form this species extremely resembles the ogotona hare, but is smaller, measuring near six inches, but weighing only from three ounces and a quarter to four and a half, and in winter two and a half. It is an inhabitant of the south-east parts of Russia, and about all the ridge of hills spreading southward from the Uralian chain; as well as about the Irtish, and the west part of the Altaic chain. It is an animal of a solitary disposition, and is very rarely to be seen, even in the places it most frequents.

Lepus, in astronomy, a constellation of the southern hemisphere, comprehending 12 stars according to Ptolemy; thirteen, according to Tycho; and nineteen in the Britannic catalogue.

LERCHEA, a genus of the class and order monadelphia pentandria. The cal. is five-toothed; cor. funnel-form, five-cleft; anthers, five; style, one; caps. three-celled, many-seeded. There is one species, a shrub of the East Indies.

LERNEA, in zoology; a genus of insects of the order of vermes mollusca, the characters of which are: the body fixes itself by its tentacula, is oblong, and rather tapering; there are two ovaries like tails, and the tentacula are shaped like arms. The cyprinacea has four tentacula, two of which are lunulated at the top. It is a small species, about half an inch long, and of the thickness of a small straw. It is found on the sides of the bream, carp, and roach, in many of our ponds and rivers, in great abundance. 2. The salmonea, or salmon-louse, has an ovated body, cordated thorax, and two linear arms, approaching nearly to each other. 3. The asellina, has a lunated body and cordated thorax; and inhabits the gills of the cod-fish and ling of the northern ocean.

LESKIA, a genus of the class and order cryptogamia musci; a moss of little note.

LESSOR and Lessee, in law. See Lease.

LET Fall, a word of command at sea, to put out a sail when the yard is aloft, and the sail is to come or fall down from the yard; but, in strictness, only applied to the main and fore courses, when their yards are hoisted up.

LETTER. A servant of the post-office is within the penalty of 5 Geo. III. c. 25, which makes it a capital felony to secrete a letter containing any bank-note, though he has not taken the oath required by 9 Anne c. 10. But to secrete a letter containing money, is not an offence within the statutes concerning the servants of the post-office.

Letter *of credit*, is where a merchant or correspondent writes a letter to another, requesting him to credit the bearer with a certain sum of money.

Letter *of licence*, is a written permission granted to a person under embarrassment, allowing him to conduct his affairs for a certain time without being molested. Such instrument will bind all the creditors by whom it is executed, and it generally contains certain stipulations to be observed by all parties.

Letter *of attorney*, is an instrument giving to a second person the authority to do any lawful act in the stead of the maker. They are sometimes revokable and sometimes not; in the latter case the word irrevocable is inserted. The authority must be strictly pursued: and if the attorney does less than the power it shall be void; if more, it shall be good as far as the power goes, and void as to the rest; but both these rules have many exceptions. See 1 Inst. 258.

LETTERS. The rate of postage of general-post letters is regulated by distance in the following proportions:

For every letter not exceeding 15 miles, 3*d*, 30 miles, 4*d*, 50 miles, 5*d*, 80 miles, 6*d*, 120 miles, 7*d*, 180 miles, 8*d*, 230 miles, 9*d*, 300 miles, 10*d*. Where the distance is under or above 100 miles, and more than 300 miles, an additional 1*d*, and so on for every further 100 miles; and all letters to and from Ireland conveyed by packet-boats shall be paid 2*d* above all other rates: for all letters to or from Portugal, or the British dominions in America, 1*s*; and to any places without the king's dominions, 4*d* additional; and all foreign letters must be charged with the full inland rates of postage.

No letter shall be rated higher than as a treble letter, if less than 1 oz. in weight, and if an oz. than as four single letters; and so in proportion of ¼ of an oz. as a letter. These rates were settled by 41 Geo. III. c. 7.

All letters on his majesty's business are free; also all peers and members of the house of commons may send daily 10 letters free and receive 15, not exceeding 1 oz. each in weight, provided the franked letters sent by them shall be indorsed with their name, and the date when the letters are put in written at full length, and the whole direction to be in the hand-writing of such member of parliament. Also, provided such member of parliament shall be within 20 miles of the post town, where letters are put in franked by him, or where letters are received directed to him. 43 Geo. III. c. 31.

Letters, *threatening*. To send letters threatening to accuse a person of any crime punishable with death or any infamous punishment, and knowingly to send any anonymous or fictitious letter threatening to kill any one, or set fire to their tenements or property, with a view of extorting money or valuables from them, is in the first instance punishable with fine, imprisonment, pillory, whipping, or transportation for seven years, and in the other instance is felony without benefit of clergy.

Letters *patent*. See Patents, and Exemplification of Patents.

Letters, *close*, are grants of the king specially distinguished from letters patent, in that the letters close, being not of public concern, but directed to particular persons, are closed up and sealed.

Letters *of marque*, are extraordinary commissions, granted to captains or merchants for reprisals, in order to make a reparation for those damages they have sustained, or the goods they have been deprived of by strangers at sea.

These appear to be always joined to those of reprise, for the reparation of a private injury; but under a declared war the former only are required.

LETHARGY. See Medicine.

LEVARI facias, is a writ directed to the sheriff for levying a certain sum of money upon the lands, &c. of a person who has forfeited his recognizance.

LEUCITE. This stone is usually found in volcanic productions, and is very abundant in the neighbourhood of Vesuvius. It is always crystallized. The primitive form of its crystals is either a cube or a rhomboidal dodecahedron, and its integrant molecules are tetrahedrons; but the varieties hitherto observed are all polyhedrons. The most common has a spheroidal figure, and is bounded by 24 equal and similar trapezoids; sometimes the faces are 12, 18, 36, 54, and triangular, pentagonal, &c. The crystals vary from the size of a pin's head to that of an inch.

The texture of the leucite is foliated; its fracture somewhat conchoidal; specific gravity from 2.455 to 2.490; colour white, or greyish white. Its powder causes syrup of violets to assume a green colour. Infusible by the blowpipe. Gives a white transparent glass with borax. It is composed, as Klaproth has shewn, of

54 silica
23 alumina
22 potass

99.

It was by analysing this stone that Klaproth discovered the presence of potass in the mineral kingdom, which is not the least important of the numerous discoveries of that accurate and illustrious chemist.

Leucite is found sometimes in rocks which have never been exposed to volcanic fire; and Mr. Dolomieu has rendered it probable, from the substances in which it is found, that the leucite of volcanoes has not been formed by volcanic fire, but that it existed previously in the rocks upon which the volcanoes have acted, and that it was thrown out unaltered in fragments of these rocks.

LEUCOJUM, *great snow-drop*, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the ninth order, spathaceæ. The corolla is campanulated, sexpartite, the segments increased at the points, the stigma simple. The species are, 1. The vernum, or spring leucojum, has an oblong bulbous root, sending up a naked stalk, about a foot high, terminated by a spatha, protruding one or two white flowers, appearing in March. 2. The æstivum, or summer leucojum, has a large oblong bulbous root, an upright stalk, 15 or 18 inches high, terminated by many white flowers in May. 3. The autumnale has a large oblong bulbous root, narrow leaves, an upright stalk, terminated by white flowers in autumn. 4. The shumosum, with flowers white within, purplish without.

LEUCOMA. See Surgery.

LEVEL, an instrument used to make a line parallel to the horizon, and to continue it out at pleasure; and by this means to find the true level, or the difference of ascent or descent, between two or more places, for conveying water, draining fens, &c.

There are several instruments, of different contrivance and matter, invented for the perfection of levelling; but they may be reduced to the following kinds:

Water-Level, that which shews the horizontal line by means of a surface of water or other fluid, founded on this principle, that water always places itself level or horizontal.

The most simple kind is made of a long wooden trough or canal, which being equally filled with water, its surface shews the line of level.

The water-level is also made with two cups fitted to the two ends of a straight pipe, about an inch diameter, and three or four feet long, by means of which the water communicates from the one cup to the other; and this pipe being moveable on its stand by means of a ball and socket, when the two cups shew equally full of water, their two surfaces mark the line of level.

This instrument, instead of cups, may also be made with two short cylinders of glass three or four inches long, fastened to each extremity of the pipe with wax or mastic. The pipe is filled with common or coloured water, which shews itself through the cylinders, by means of which the line of level is determined; the height of the water, with respect to the centre of the earth, being always the same in both cylinders. This level, though very simple, is yet very commodious for levelling small distances.

Air-Level, that which shews the line of level by means of a bubble of air inclosed with some fluid in a glass tube of an indeterminate length and thickness, and having its two ends hermetically sealed. When the bubble fixes itself at a certain mark, made exactly in the middle of the tube, the case or ruler in which it is fixed is then level. When it is not level, the bubble will rise to one end. This glass tube may be set in another of brass, having an aperture in the middle, where the bubble of air may be observed. It should be filled with a liquid not liable to freeze nor evaporate.

There is one of these instruments with sights, being an improvement upon that last described, which, by the addition of other apparatus, becomes more exact and commodious. It consists of an air-level (Plate Miscel. fig. 146) about eight inches long, and about two-thirds of an inch in diameter, set in a brass tube 2, having an aperture in the middle C. The tubes are carried in a straight ruler, of a foot long; at the ends of which are fixed two sights 3, 3, exactly perpendicular to the tubes, and of an equal height, having a square hole, formed by two fillets of brass crossing each other at right angles; in the middle of this is drilled a very small hole, through which a point on a level with the instrument is seen. The brass tube is fastened to the ruler by means of two screws; the one of which, marked 4, serves to raise or depress the tube at pleasure, for bringing it towards a level. The top of the ball and socket is rivetted to a small ruler that springs, one end of which is fastened with springs to the great ruler, and at the other end is a screw 5, serving to raise and depress the instrument when nearly level.

But this instrument is still less commodious than the following one: for though the holes are ever so small, yet they will still take in too great a space to determine the point of level precisely.

Fig. 147. is a level with telescopic sights, first invented by Mr. Huygens. It is like the last, with this difference, that instead of plain sights it carries a telescope to determine exactly a point of level at a considerable distance. The screw 3, is for raising or lowering a little fork for carrying the hair, and making it agree with the bubble of air when the instrument is level; and the screw 4 is for making the bubble of air, D or E, agree with the telescope. The whole is fitted to a ball and socket, or otherwise moved by joints and screws. It may be observed, that a telescope may be added to any kind of level, by applying it upon, or parallel to, the base or ruler, when there is occasion to take the level of remote objects; and it possesses this advantage, that it may be inverted by turning the ruler and telescope half-round; and if then the hair cut the same point that it did before, the operation is just. Many varieties and improvements of this instrument have been made by the more modern opticians.

Dr. Desaguliers proposed a machine for taking the difference of level, which contained the principles both of a barometer and thermometer; but it is not accurate in practice.

Reflecting Level, that made by means of a pretty long surface of water, representing the same object inverted, which we see erect by the eye; so that the point where these two objects appear to meet, is on a level with the place where the surface of the water is found.

There is another reflecting level, consisting of a polished metal mirror, placed a little before the object-glass of a telescope, suspended perpendicularly. This mirror must be set at an angle of 45 degrees; in which case the perpendicular line of the telescope becomes a horizontal line, or a line of level: which is the invention of M. Cassini.

Artillery Foot-Level, is in form of a square (fig. 148.), having its two legs or branches of an equal length; at the junction of which is a small hole, by which hangs a plummet playing on a perpendicular line in the middle of a quadrant, which is divided both ways from that point into 45 degrees.

This instrument may be used on other occasions by placing the ends of its two branches on a plane; for when the plummet plays perpendicularly over the middle division of the quadrant, the plane is then level.

To use it in gunnery, place the two ends on the piece of artillery, which may be raised to any proposed height by means of the plummet, which will cut the degree above the level. But this supposes the outside of the cannon is parallel to its axis, which is not always the case; and therefore they use another instrument now, either to set the piece level, or elevate it at any angle; namely a small quadrant, with one of its radii continued out pretty long, which being put into the inside of the cylindrical bore, the plummet shews the angle of elevation, or the line of level.

Carpenter's, *Bricklayer's*, or *Pavior's* Level, consists of a long ruler, in the middle of which is fitted at right angles another broader piece, at the top of which is fastened a plummet, which when it hangs over the middle line of the second or upright piece, shews that the base or long ruler is horizontal or level. Fig. 149.

Mason's Level, is composed of three rulers, so jointed as to form an isosceles triangle, somewhat like a Roman A; from the vertex of which is suspended a plummet, which hangs directly over a mark in the middle of the base, when this is horizontal or level.

Plum or *Pendulum* Level, said to be invented by M. Picard, fig. 150. This shews the horizontal line by means of another line perpendicular to that described by a plummet or pendulum. This level consists of two legs or branches, joined at right angles, the one of which, of about 18 inches long, carries a thread and plummet; the thread being hung near the top of the branch, at the point 2. The middle of the branch where the thread passes is hollow, so that it may hang free every where: but towards the bottom, where there is a small blade of silver, on which a line is drawn perpendicular to the telescope, the said cavity is covered by two pieces of brass, with a piece of glass G, to see the plummet through, forming a kind of case, to prevent the wind from agitating the thread. The telescope, of a proper length, is fixed to the other leg of the instrument, at right angles to the perpendicular, and having a hair stretched horizontally across the focus of the object-glass, which determines the point of level, when the string of the plummet hangs against the line on the silver blade. The whole is fixed by a ball and socket to its stand.

Fig. 151. is a *Balance* Level, which being suspended by the ring, the two sights, when in equilibrio, will be horizontal, or in a level.

But the most complete level is the *Spirits* Level, invented by the late Mr. Ramsden. See Plate Spirits Level. ABD, fig. 7. are the three legs upon which it is placed; when shut up, they form one round rod, and are kept together by three rings: these legs are jointed to a brass frame E, on the top of which is a male screw, screwing into a female screw within the projection *a* of the plate F. Within the top of *a*, figs. 4 and 7, is a hemispherical cavity to contain the spherical ball, fig. 5: this ball has a male screw *d* on its top, which screws into a female screw *b*, fig. 6, in the plate G, fig. 7 and fig. 6, the ball is put up through an opening *c*, fig. 4, and screwed to the plate, fig. 6; so that the upper plate G can move in any direction within certain limits by the play of the ball in its socket; to confine the upper plate G when it is set in any direction, four screws, HHHH, figs. 4 and 7, are employed; they work in tubes firmly fixed to the plate F, and are turned by their milled heads; the upper ends of these screws act against the under side of the plate, fig. 6, as shewn in fig. 7; so that when the plate G is required to be moved in any direction, it is done by screwing up one screw and screwing down the opposite till it is brought to the proper inclination; then by screwing up both together, the plate is firmly fixed. The ball, fig. 5, has a conical hole *f* through it, to receive an axis which is screwed fast to the bottom of the compass-box I, fig. 7; a screw screwed into the end of this axis prevents its being lifted out, and at the same time leaves it at liberty to turn round independant of the ball, fig. 5. On each side of the compass-box I, is a bar KK, on the end of which are fixed two forked pieces IO, called the Y's (from their resemblance to that letter), carrying the telescope M. One of these (O) is capable of being raised or lowered by means of a milled-headed screw N, which works through a collar in the lower end of the tube g; the rest of the tube has a triangular hole through it, in which slides a bar k, which is part of the Y; O the female screw is cut within this bar, and the screw works into it, so that by turning the milled head one way, the Y is raised, and by reversing the motion, it is lowered. The axis which connects the compass-box and the other apparatus, has a collar upon it just above where it enters the ball, fig. 5, which is embraced by a clamp P, fig. 6, which is closed by a screw C, so as to hold the collar of the axis quite tight; and when the screw is turned back, its own elasticity opens it so as to allow the axis of the compass-box to turn round freely within it; on the opposite side of the clamp is a projecting arm l, carrying the nut m of the screw Q, which screw works in a stud n, fixed to the upper plate G, figs. 7 and 6; by this means, when G is loosened, the telescope can be turned quite round, but when it is fastened, it can only be moved by turning the screw Q. The level-tube Z is fastened to the under side of the telescope by a screw q at one end and a bar r at the other: the use of these are to adjust it so that it shall be exactly parallel to the axis of the telescope-tube. The level, as best explained in the section, fig. 1, is a tube of glass ss, nearly filled with spirits of wine, but so as to leave a bubble of air in it; if the tube is of exactly the same diameter in every part, the bubble will rest in the middle of the tube when it is level. In some of the best levels made by Ramsden, the inside of the tube is bent into a segment of a circle, 100 feet diameter, and the inside is ground, which causes the bubble to adhere together; if the tube is straight, it is liable to divide into several small ones. The internal parts of the telescope are explained in fig. 1: RR is the external tube of brass plate; within this slides another tube ss; it has two glasses v, w, screwed into the outer end, called object-glasses, and it has two divisions x, y, called diaphagram, with small holes in them; their use is to collect the prismatic rays with which the objects would otherwise be tinged; the tube ss has a rack t fixed nearly in the middle of it, which takes into a pinion on the axis of the milled head T, figs. 1 and 7; by turning this, the glasses v, w, can be moved nearly to, or farther from, the eye to adjust the focus; to the tube R at v are fixed the cross wires, whose intersection is exactly in the centre of the tube. The manner of fixing these is explained in fig. 3: A is a brass box, which fits into the end of the telescope-tube, and is held there by four small screws; within this box is placed a brass plate B, carrying the wires, which are fastened by screwing four screws down upon their ends; when the plate B is in the box, a ring D is screwed in upon it, which prevents its falling out, but at the same time leaves it at liberty to move about in the box; the sides of the box, and also the telescope-tube, has four rectangular holes in it, through which four screws are passed into the edges of the piece B, so as to hold it in any position: these screws come through the external tube, and have square heads, to be turned by a key, so as to adjust the interactions in the centre: the box A has a female screw in the front, into which is screwed the eye-piece W; 3 is the tube which is screwed to the telescope; within this slides a tube, containing two glasses 4, 5; by sliding the glasses in or out of the tube 3, they can be adjusted so as to adapt their focus to the cross wires. This eye-piece is convenient on account of its shortness; but as it reverses the objects, it is sometimes more convenient to use the eye-piece fig. 2, which is much longer, but does not reverse objects. a is the tube which is screwed to the telescope; within this slides another tube bb, having at one end a tube dd, containing two glasses ef, and a diaphagram g, and at the other end a tube hh, containing two glasses ik, and a diaphagram: m is a cap screwed on to the end to prevent the tubes coming out. When the instrument is to be carried, the level is unscrewed from the legs and packed in a case; the legs are shut up and kept so by the rings, as before described. The manner of using this instrument is as follows: When the difference of level between any two places is required, the observer with the level goes to the highest of the two, and his assistant goes to the lowest with the target, which is a long pole of wood with a groove in it, in which slides a small rod carrying a round piece of wood, called a sight, which is to be observed through the telescope; the observer opens the legs of the instrument, and sets them on the ground; the level is next screwed to them at E, as shewn in fig. 7; the telescope is then brought nearly to a level by the screws HHHH, as before described; the screw c is then turned so as to release the clamp P, fig. 6; and the telescope is turned about, so as to point to the target; the clamp P is then closed, the observer looks through the telescope, and by turning the nut T, the focus is adjusted: the screw Q is then turned till the cross wires are brought to coincide with the object, in an horizontal plane; he then takes his eye from the telescope, and works the screw N till he brings the bubble of air in the level-tube exactly in the middle, which shews that the telescope is perfectly horizontal; the observer then makes signals to the assistant to raise or lower the sight on the slider of the target, till it is brought to coincide with the intersection of the cross wire, which shews that the telescope and the sight of the target are on the same level; the height which the sight is from the ground where the target stands, deducted from the height the telescope stands from the ground, is the difference of level required.

LEVELLING, the art or act of finding a line parallel to the horizon at one or more stations, to determine the height or depth of one place with respect to another; for laying out grounds even, regulating descents, draining morasses, conducting water, &c.

Two or more places are on a true level when they are equally distant from the centre of the earth. Also one place is higher than another, or out of level with it, when it is farther from the centre of the earth; and a line equally distant from that centre in all its points, is called the line of true level. Hence, because the earth is round, that line must be a curve, and make a part of the earth's circumference, or at least parallel to it, or concentrical with it; as the line BCFG (Plate Misc. fig. 152), which has all its points equally distant from A, the centre of the earth, considering it as a perfect globe.

But the line of sight BDE, &c. given by the operations of levels, is a tangent, or a right line perpendicular to the semidiameter of the earth at the point of contact B, rising always higher above the true line of level, the farther the distance is, is called the apparent line of level. Thus, CD is the height of the apparent level above the true level, at the distance BC or BD; also EF is the excess of height at F, and GH at G, &c. The difference, it is evident, is always equal to the excess of the secant of the arch of distance above the radius of the earth.

The common methods of levelling are sufficient for laying pavements of walks, or for conveying water to small distances, &c.; but in more extensive operations, as in levelling the bottoms of canals, which are to convey water to the distance of many miles, and such like, the difference between the true and the apparent level must be taken into the account.

Now the difference CD between the true and apparent level, at any distance BC or BD, may be found thus: By a well-known property of the circle, 2AC + CD : BD :: BD : CD; or because the diameter of the earth is so great with respect to the line CD at all distances to which an operation of levelling commonly extends, that 2AC may be safely taken for 2AC + CD in that proportion without any sensible error, it will be 2AC : BD :: BD : CD, which therefore is $= \frac{BD^2}{2AC}$, or $\frac{BC^2}{2AC}$ nearly; that is, the difference between the true and apparent level, is equal to the square of the distance between the places, divided by the diameter of the earth; and consequently it is always proportional to the square of the distance.

Now the diameter of the earth being nearly 7958 miles; if we first take BC = 1 mile, then the excess $\frac{BC^2}{2AC}$ becomes $\frac{1}{7958}$ of a mile, which is 7.962 inches, or almost 8 inches, for the height of the apparent above the true level at the distance of one mile. Hence, proportioning the excesses in altitude according to the squares of the distances, the following Table is obtained, shewing the height of the apparent above the true level for every 100 yards of distance on the one hand, and for every mile on the other.

Dist. or BC.	Dif. of Level, or CD.	Dist. or BC.	Dif. of Level, or CD.	
Yards.	Inches.	Miles.	Feet.	Inc.
100	0.026	$\frac{1}{4}$	0	$0\frac{1}{2}$
200	0.103	$\frac{1}{2}$	0	2
300	0.231	$\frac{3}{4}$	0	$4\frac{1}{2}$
400	0.411	1	0	8
500	0.643	2	2	8
600	0.925	3	6	0
700	1.260	4	10	7
800	1.645	5	16	7
900	2.081	6	23	11
1000	2.570	7	32	6
1100	3.110	8	42	6
1200	3.701	9	53	9
1300	4.344	10	66	4
1400	5.038	11	80	3
1500	5.784	12	95	7
1600	6.580	13	112	2
1700	7.425	14	130	1

By means of tables of reductions, we can now level to almost any distance at one operation, which the antients could not do but by a great multitude; for, being unacquainted with the correction answering to any distance, they only levelled from one 20 yards to another, when they had occasion to continue the work to some considerable extent.

This table will answer several useful purposes. Thus, first, to find the height of the apparent level above the true, at any distance. If the given distance is in the table, the correction of level is found on the same line with it: thus at the distance of 1000 yards, the correction is 2·57, or two inches and a half nearly; and at the distance of 10 miles, it is 66 feet 4 inches. But if the exact distance is not found in the table, then multiply the square of the distance in yards by 2·57, and divide by 1,000,000, or cut off six places on the right for decimals; the rest are inches: or multiply the square of the distance in miles by 66 feet 4 inches, and divide by 100.

2dly, To find the extent of the visible horizon, or how far can be seen from any given height, on a horizontal plane, as at sea, &c. Suppose the eye of an observer, on the top of a ship's mast at sea, is at the height of 130 feet above the water, he will then see about 14 miles all around. Or from the top of a cliff by the sea-side, the height of which is 66 feet, a person may see to the distance of near 10 miles on the surface of the sea. Also, when the top of a hill, or the light in a lighthouse, or such like, whose height is 130 feet, first comes into the view of an eye on board a ship, the table shews that the distance of the ship from it is 14 miles, if the eye is at the surface of the water; but if the height of the eye in the ship is 80 feet, then the distance will be increased by near 11 miles, making in all about 25 miles distance.

3dly, Suppose a spring to be on one side of a hill, and a house on an opposite hill, with a valley between them, and that the spring seen from the house appears by a levelling instrument to be on a level with the foundation of the house, which suppose is at a mile distance from it; then is the spring eight inches above the true level of the house; and this difference would be barely sufficient for the water to be brought in pipes from the spring to the house, the pipes being laid all the way in the ground.

4th, If the height or distance exceed the limits of the table, then, first, if the distance be given, divide it by 2, or by 3, or by 4, &c. till the quotient come within the distances in the table; then take out the height answering to the quotient, and multiply it by the square of the divisor, that is, by 4, or 9, or 16, &c. for the height required: so if the top of a hill is just seen at the distance of 40 miles, then 40 divided by 4 gives 10, to which in the table answer 66⅓ feet, which being multiplied by 16, the square of 4, gives 1061⅓ feet for the height of the hill. But when the height is given, divide it by one of these square numbers 4, 9, 16, 25, &c. till the quotient come within the limits of the table, and multiply the quotient by the square root of the divisor, that is by 2, or 3, or 4, or 5, &c. for the distance sought: so when the top of the peak of Teneriffe, said to be almost 3 miles, or 15840 feet high, just comes into view at sea, divide 15840 by 225, or the square of 15, and the quotient is 70 nearly; to which in the table answers by proportion nearly 10$\frac{2}{7}$ miles; then multiplying 10$\frac{2}{7}$ by 15, gives 154 miles and $\frac{2}{7}$, for the distance of the hill.

The operation of levelling is as follows: Suppose the height of the point A (Plate Miscel. fig. 153.) on the top of a mountain, above that of B at the foot of it, is required. Place the level about the middle distance at D, and set up pickets, poles, or staffs at A and B, where persons must attend with signals for raising and lowering, on the said poles, little marks of pasteboard or other matter. The level having been placed horizontally by the bubble, &c. look towards the staff AE, and cause the person there to raise or lower the mark till it appears through the telescope or sights, &c. at E: then measure exactly the perpendicular height of the point E above the point A, which suppose 5 feet 8 inches, and set it down in your book. Then turn your view the other way towards the pole B, and cause the person there to raise or lower his mark, till it appears in the visual line as before at C; and measuring the height of C above B, which suppose 15 feet 6 inches, set this down in your book also, immediately above the number of the first observation. Then subtract the one from the other, and the remainder 9 feet 10 inches will be the difference of level between A and B, or the height of the point A above the point B.

If the point D, where the instrument is fixed, is exactly in the middle between the points A and B, there will be no necessity for reducing the apparent level to the true one, the visual ray on both sides being raised equally above the true level. But if not, each height must be corrected or reduced according to its distance, before the one corrected height is subtracted from the other.

When the distance is very considerable or irregular, so that the operation cannot be effected at once placing of the level, or when it is required to know if there is a sufficient descent for conveying water from the spring A to the point B (fig. 154.), this must be performed at several operations. Having chosen a proper place for the first station, as at I, fix a pole at the point A near the spring, with a proper mark to slide up and down it, as L; and measure the distance from A to I. Then the level being adjusted in the point T, let the mark L be raised or lowered till it is seen through the telescope or sights of the level, and measure the height AL. Then having fixed another pole at H, direct the level to it, and cause the mark G to be moved up or down till it appears through the instrument; then measure the height GH, and the distance from I to H, noting them down in the book. This done, remove the level forwards to some other eminence as E, from whence the pole H may be viewed, as also another pole at D; then having adjusted the level in the point E, look back to the pole H; and managing the mark as before, the visual ray will give the point F; then measuring the distance HE and the height HF, note them down in the book. Then, turning the level to look at the next pole D, the visual ray will give the point D; there measure the height of D, and the distance EB, entering them in the book as before. And thus proceed from one station to another till the whole is completed.

But all these heights must be corrected or reduced by the foregoing table, according to their respective distances; and the whole, both distances and heights, with their corrections, entered in the book in the following manner:

Back-sights. Dists. yds.	Back-sights. Hts. ft. in.	Back-sights. Cors. inc.	Fore-sights. Dists. yds.	Fore-sights. Hts. ft. in.	Fore-sights. Cors. inc.
IA 1650	AL 11 3	7.0	IH 1265	HG 19 5	4.0
EH 940	HF 10 7	2.2	EB 900	ED 8 1	2.1
2590	21 10	9.2	2165	27 6	6.1
	9.2		2590	6.1	
	21 0.8		Dist. 4755	26 11.9	
				21 0.8	
			Whole Dif. of level	5 11.1	

Having summed up all the columns, add those of the distances together, and the whole distance from A to B is 4755 yards, or two miles and three quarters nearly. Then the sums of the corrections taken from the sums of the apparent heights, leave the two corrected heights; the one of which being taken from the other, leaves 5 feet 11·1 inches for the true difference of level sought between the two places A and B, which is at the rate of an inch and a half nearly to every 100 yards, a quantity more than sufficient to cause the water to run from the spring to the house.

Or the operation may be otherwise performed, thus: Instead of placing the level between every two poles, and taking both back-sights and fore-sights, plant it first at the spring A, and from thence observe the level to the first pole; then remove it to this pole, and observe the second pole; next move it to the second pole, and observe the third pole; and so on, from one pole to another, always taking foreward sights or observations only. And then at the last, add all the corrected heights together, and the sum will be the whole difference of level sought.

Levelling-staves, instruments used in levelling, serving to carry the marks to be observed, and at the same time to measure the heights of those marks from the ground. They usually consist each of two long wooden rulers, made to slide over one another, and divide into feet, inches, &c.

LEVER. See Mechanics.

LEVIGATION. See Pharmacy.

LEVISANUS, a genus of the class and order pentandria monogynia. The flowers are aggregate; corolla one-leafed, superior, five-cleft; filaments inserted into the base of the perianthium; styles two, conjoined; seeds five or six. There are five species, shrubs of the Cape.

LEYDEN PHIAL. See Electricity.

LEYSERA, a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; the pappus paleaceous;

that of the disc plumy; the calyx scarious. There are three species, shrubs of the Cape.

LIATRIS, a genus of the class and order syngenesia polygamia æqualis. The calyx is oblong, imbricate, awnless, coloured down, feathered coloured; receptacle naked, hollow, dotted. There are eight species, herbs of America.

LIBEL, injurious reproaches or accusations written and published against the memory of one who is dead, or the reputation of one who is alive, and thereby exposing him to public hatred, contempt, and ridicule.

With regard to libels in general, there are, as in many other cases, two remedies; one by indictment or information, and the other by action. The former for a public offence; for every libel has a tendency to the breach of the peace, by provoking the person libelled to break it; which offence is said to be the same in point of law, whether the matter contained is true or false; and therefore it is that the defendant on an indictment for publishing a libel, is not allowed to allege the truth of it by way of justification. But in the remedy by action on the case, which is to repair the party in damages for the injury done him, the defendant may, as for words spoken, justify the truth of the facts, and shew that the plaintiff has received no injury at all. The chief excellence therefore of a civil action for a libel consists in this, that it not only affords a reparation for the injury sustained, but it is a full vindication of the innocence of the person traduced. 3 Black. 125.

By a late statute, the jury are acknowledged to be judges both of the law and the fact.

LIBEL, in the ecclesiastical court, is the declaration or charge drawn up in writing, on the part of the plaintiff, to which the defendant is obliged to answer.

LIBEL, in the law of Scotland, signifies an indictment.

LIBELLULA, *dragon-fly*, a genus of insects of the order neuroptera. The generic character is: mouth furnished with several jaws; antennæ very short; wings four, extended; tail (in the male) hook-forcipated.

The libellulæ, or dragon-flies, sometimes called by the very improper title of horse-stingers, exhibit an instance scarcely less striking than the butterfly of that strange dissimilitude in point of form under which one and the same animal is destined to appear in the different periods of its existence. Perhaps few persons not particularly conversant in the history of insects, would imagine that these highly brilliant and lively animals, which may be seen flying with such strength and rapidity round the meadows, and pursuing the smaller insects with the velocity of a hawk, had once been inhabitants of the water, and that they had resided for a very long space of time in that element before they assumed their flying form. Of the libellulæ there are many different species, both native and exotic. The most remarkable of the English species is the libellula varia, or great variegated libellula. This insect makes its appearance principally towards the decline of summer, and is an animal of singular beauty: its general length is about three inches from head to tail, and the wings, when expanded, measure near four inches from tip to tip; the head is very large, and affixed to the thorax by an extremely slender neck; the eyes occupy by far the greatest part of the head, and are of a pearly blue-grey cast, with a varying lustre; the front is greenish yellow; the thorax of the same colour, but marked by longitudinal black streaks; the body, which is very long, slender, and subcylindrical, is black, with rich variegations of bright blue, and deep grass-green; the wings are perfectly transparent, strengthened by very numerous black reticular fibres, and exhibit a strongly iridescent appearance, according to the various inflexions of light; each is marked near the tip by a small oblong square black spot on the outer edge; the legs are black, and the tail is terminated by a pair of black forcipated processes, with an intermediate shorter one of similar colour. Sometimes this insect varies; the spots or marks on the abdomen and thorax being red or red-brown instead of green.

The female libellula deposits or drops her eggs into the water, which sinking to the bottom, are hatched, after a certain period, into hexapode flattish larvæ or caterpillars, of a very singular and disagreeable aspect. They cast their skins several times before they arrive at their full size, and are of a dusky brown colour. The rudiments of the future wings appear on the back of such as are advanced to what may be called the pupa or chrysalis state, in the form of a pair of oblong scales or processes, and the head is armed with a most singular organ for seizing its prey, viz. a kind of proboscis, of a flattened form, and furnished with a joint in the middle, the end being much dilated, and armed with a pair of strong hooks or prongs. This proboscis, when the animal is at rest, is folded or turned up in such a manner as to lap over the face like a mask; but when the creature sees any insect which it means to attack, it springs suddenly forwards, and by stretching forth the jointed proboscis, readily obtains its prey. They continue in this their larva and pupa state for two years, when, having attained their full size, they prepare for their ultimate change; and creeping up the stem of some water-plant, and grasping it with their feet, they make an effort, by which the skin of the back and head is forced open, and the inclosed libellula gradually emerges. The wings, at this early period of exclusion, like those of butterflies, are very short, tender, and contracted, all the ramifications or fibres having been compressed within the small compass of the oblong scales on the back of the larva, or pupa; but in the space of about half an hour, they are fully expanded, and have acquired the solidity and strength necessary for flight. This curious process of the evolution or birth of the libellula generally takes place in the morning, and during a clear sunshine. The remaining part of the animal's life is but short in comparison with that which it passed in its aquatic state, the frosts of the close of autumn destroying the whole race. They are also the prey of several sorts of birds.

The libellula depressa is a smaller or shorter species than the preceding, though with a considerably broader body in proportion. The male is of a bright sky-blue, with the sides of the body yellow; the female of a fine brown or bay, with yellow sides also. The wings in both sexes are transparent, except at the shoulders, where they are each marked by a broad bed or patch of brown with a stripe of yellow; the tips of each wing have also a small oblong-square black spot on the outer margin. The larva of this species is of a shorter form than that of the preceding, and is of a greenish-brown colour.

The libellula virgo is one of the most elegant of the European insects. It is much smaller than the libellula varia, and is distinguished by its very slender, long, cylindric body, which, as well as the head and thorax, is usually either of a bright but deep golden green, or else of a deep gilded blue. The wings are transparent at the base and tips, but are each marked in the middle by a very large oval patch or bed of deep blackish or violet blue, accompanied with iridescent hues according to the direction of the light: sometimes the wings are entirely violet-black, without the least appearance of transparency either at the base or tips; and sometimes they are altogether transparent, without any appearance of the violet-black patch which distinguishes the majority of specimens; and lastly the insect sometimes appears with transparent wings, but shaded with a strong cast of gilded greenish brown, each being marked by a small white speck at the exterior edge, near the tip.

A much smaller species than the preceding, and equally common, is the libellula puella of Linnæus. This varies much in colour, but is generally of a bright and beautiful sky-blue, variegated with black bars on the joints, and with the thorax marked by black longitudinal stripes. The wings are transparent, and each marked near the tip with a small oblong-square black marginal spot.

The exotic libellulæ are very numerous. Among the most remarkable may be numbered the L. lucretia. It is a native of the Cape of Good Hope, and is distinguished by the excessive length of its slender body, which measure not less than five inches and a half in length, though scarcely exceeding the tenth of an inch in diameter. The wings are transparent, of a slender or narrow shape, as in the L. puella, to which this species is allied in form, and measure five inches and a half in extent from tip to tip. The colour of the head and thorax is brown, with a yellowish stripe on each side, and the body is of a deep mazarine-blue. See Plate Nat. Hist. figs. 250, 251.

LIBERTUS, in Roman antiquity, a person who from being a slave, had obtained his freedom. The difference between the liberti and libertini was this: the liberti were such as had been actually made free themselves, and the libertini were the children of such persons.

LIBRA, *the balance*, in astronomy, one of the twelve signs of the zodiac, the sixth in order; so called because when the sun enters it, the days and nights are equal, as if weighed in a balance.

Authors enumerate from ten to forty-nine stars in this sign.

LIBRA, in Roman antiquity, a pound weight; also a coin, equal in value to twenty denarii.

LIBRATION, in astronomy, an apparent irregularity of the moon's motion, whereby she seems to librate about her axis, sometimes from the east to the west, and now and then from the west to the east; so that the parts in the western limb or margin of the moon sometimes recede from the centre of the disk, and sometimes move towards it, by which means they become alternately visible and invisible to the inhabitants of the earth.

Libration *of the earth*, is sometimes used to denote the parallelism of the earth's axis, in every part of its orbit round the sun.

LICENCE, in law, an authority given to a person to do some lawful act.

A licence is a personal power, and therefore cannot be transferred to another. If the person licensed abuse the power given him, in that case he becomes a trespasser.

LICENTIATE, one who has obtained the degree of a licence. The greatest number of the officers of justice in Spain are distinguished by no other title but that of licentiate. In order to pass licentiate in common law, civil law, and physic, they must have studied seven years; and in divinity, ten. Among us, a licentiate usually means a physician who has a licence to practise, granted by the college of physicians, or the bishop of the diocese.

LICHEN, *liverwort*, a genus of the natural order of algæ, in the cryptogamia class of plants. The male receptacle is roundish, somewhat plain and shining. In the female the leaves have a farina or mealy substance scattered over them. There are about 216 species, all found in Britain. Among the most remarkable are the following:

1. The geographicus; it is frequent in rocks, and may be readily distinguished at a distance. The crust or ground is of a bright greenish-yellow colour, sprinkled over with numerous plain black tubercles; which frequently run into one another, and form lines resembling the rivers in a map, from which last circumstance it takes it name.

2. The calcarious, or black-nobbed dyer's lichen, is frequent on calcarious rocks; and has a hard, smooth, white, stony, or tartareous crust, cracked or tesselated on the surface, with black tubercles. Dillenius relates, that this species is used in dyeing, in the same manner as the tartareus after-mentioned.

3. The ventosus, or red spangled tartareous lichen, has a hard tartareous crust, cracked and tesselated on the surface, of a pale yellow colour when fresh, and a light olive when dry. The tubercles are of a blood-red colour at top, their margin and base of the same colour as the crust. The texture and appearance of this (according to Mr. Lightfoot) indicate that it would answer the purposes of dyeing as well as some others of this tribe, if proper experiments were made.

4. The candelarius, or yellow farinaceous lichen, is common upon walls, rocks, boards, and old pales. There are two varieties. The first has a farinaceous crust of no regular figure, covered with numerous small greenish-yellow or olive shields, and grows commonly upon old boards. The other has a smooth, hard, circular crust, wrinkled and lobed at the circumference, which adheres closely to rocks and stones. In the centre are numerous shields of a deeper yellow or orange colour, which, as they grow old, swell in the middle, and assume the figure of tubercles. The inhabitants of Smaland in Sweden scrape this lichen from the rocks, and mix it with their tallow, to make golden candles to burn on festival days.

5. The tartareus, or large yellow-saucered dyer's lichen, is frequent on rocks, both in the Highlands and Lowlands of Scotland. The crust is thick and tough, either white or greenish white, and has a rough warted surface. The shields are yellow or buff-coloured, of various sizes, from that of a pin's head to the diameter of a silver penny. Their margins are of the same colour as the crust. This lichen is much used by the Highlanders for dyeing a fine claret or pompadour colour. For this purpose, after scraping it from the rocks, and cleaning it, they steep it in urine for a quarter of a year. Then taking it out, they make it into cakes, and hang them up in bags to dry. These cakes are afterwards pulverised, and the powder is used to impart the colour with an addition of alum.

6. The parellus, or crawfish-eye lichen, grows upon walls and rocks, but is not very common. The crusts spread closely upon the place where they grow, and cover them to a considerable extent. They are rough, tartareous, and ash-coloured, of a tough coriaceous substance. The shields are numerous and crowded, having white or ash-coloured, shallow, plain discs, with obtuse margins. This is used by the French for dyeing a red colour.

7. The saxatilis, or grey-blue pitted lichen, is very common upon trunks of trees, rocks, tiles, and old wood. It forms a circle two or three inches diameter. The upper surface is of a blue grey, and sometimes of a whitish ash-colour, uneven, and full of numerous small pits or cavities; the under side is black, and covered all over, even to the edges, with short simple hairs or radicles. A variety sometimes occurs with leaves tinged of a red or purple colour. This is used by finches and other small birds in constructing the outside of their curiously formed nests.

8. The omphalodes, or dark-coloured dyer's lichen, is frequent upon rocks. It forms a thick widely expanded crust of no regular figure, composed of numerous imbricated leaves of a brown or dark-purple colour, divided into small segments. The margins of the shields are a little crisped and turned inwards, and their outside ash-coloured. This lichen is much used by the Highlanders in dyeing a reddish-brown colour. They steep it in urine for a considerable time, till it becomes soft and like a paste; then, forming the paste into cakes, they dry them in the sun, and preserve them for use in the manner already related of the tartareus.

9. The parietinus, or common yellow wall-lichen, is very common upon walls, rocks, tiles of houses, and trunks of trees. It generally spreads itself in circles of two or three inches diameter, and is said to dye a good yellow or orange-colour with alum.

10. The Islandicus, or eatable Iceland lichen, grows on many mountains both of the Highlands and Lowlands of Scotland. It consists of nearly erect leaves about two inches high, of a stiff substance when dry, but soft and pliant when moist, variously divided without order into broad distant segments, bifid or trifid at the extremities. The upper or interior surface of the leaves is concave, chesnut-colour, smooth, and shining, but red at the base; the under or exterior surface is smooth and whitish, a little pitted, and sprinkled with very minute black warts. The margins of the leaves and all the segments from bottom to top, are ciliated with small, short, stiff, hair-like spinules, of a dark chesnut-colour, turning towards the upper side. The shields are very rarely produced. Made into broth or gruel, it is said to be very serviceable in coughs and consumptions; and, according to Haller and Scopoli, is much used in these complaints in Vienna.

11. The pulmonarius, or lung-wort lichen, grows in shady woods upon the trunks of old trees. The leaves are as broad as a man's hand, of a kind of leather-like substance, hanging loose from the trunk on which it grows, and laciniated into wide angular segments. Their natural colour, when fresh, is green; but in drying, they turn first to a glaucous and afterwards to a fuscous colour. It has an astringent, bitter taste; and, according to Gmelin, is boiled in ale in Siberia, instead of hops. The antients used it in coughs and asthmas, &c. but it is not used in modern practice.

12. The calicaris, or beaked lichen, grows sometimes upon trees, but more frequently upon rocks, especially on the sea-coasts, but is not very common. It is smooth, glossy, and whitish, producing flat or convex shields, of the same colour as the leaves, very near the summits of the segments, which are acute and rigid, and, being often reflected from the perpendicular by the growth of the shields, appear from under their limbs like a hooked beak. This will dye a red colour; and promises, in that intention, to rival the famous lichen rocolla or argol, which is brought from the Canary Islands, and sometimes sold at the price of 80*l*. per ton. It was formerly used instead of starch to make hair-powder.

13. The prunastri, or common ragged hoary lichen, grows upon all sorts of trees; but it is generally most white and hoary on the sloe and old palm trees, or upon old pales. This is the most variable of the whole tribe of lichens, appearing different in figure, magnitude, and colour, according to its age, place of growth, and sex. The young plants are of a glaucous colour, slightly divided into small acute crested segments. As they grow older, they are divided like a stag's horn, into more and deeper segments, somewhat broad, flat, soft, and pitted on both sides, the upper surface of a glaucous colour, the under one white and hoary. The male plants, as Linnæus terms them, are short, seldom more than an inch high, not hoary on the under side; and have pale glaucous shields situated at the extremities of the segments, standing on short peduncles, which are only small stiff portions of the leaf produced. The female specimens have numerous farinaceous tubercles both on the edges of their leaves, and the wrinkles of their furnace. The pulverised leaves have been used as a powder for the hair, and also in dyeing yarn of a red colour.

14. The juniperinus, or common yellow tree-lichen, is common upon the trunks and branches of elms and many other trees. Linnæus says it is very common upon the juniper. The Gothland Swedes dye their yarn of a yellow colour with it, and give it as a specific in the jaundice.

15. The caninus, or ash-coloured ground liverwort, grows upon the ground among

moss, at the roots of trees in shady woods, and is frequent also in heaths and stony places. The leaves are large, gradually dilated towards the extremities, and divided into roundish elevated lobes. Their upper side, in dry weather, is ash-coloured; in rainy weather, of a dull fuscous green colour; their under-side white and hoary, having many thick downy nerves, from which descend numerous long, white, pencil-like radicles. The peltæ, or shields, grow at the extremities of the elevated lobes, shaped like the human nail; of a roundish oval form, convex above, and concave beneath; of a chocolate colour on the upper side, and the same colour with the leaves on the under. There are two varieties, the one called reddish, and the other many-fingered, ground-liverwort. The former is more common than the other. This species has been rendered famous by the celebrated Dr. Mead, who asserted that it was an infallible preventative of the dreadful consequences attending the bite of a mad dog.

16. The aphthosus, or green ground liverwort with black warts, grows upon the ground at the roots of trees in woods, and other stony and mossy places. It differs very little from the foregoing, and according to some is only a variety of it. Linnæus informs us, that the country-people of Upland in Sweden give an infusion of this lichen in milk to children that are troubled with the disorder called the thrush or aphthæ, which induced that ingenious naturalist to bestow upon it the trivial name of aphthosus. The same writer also tells us, that a decoction of it in water purges upwards and downwards, and will destroy worms.

17. The cocciferus, or scarlet-tipped cup-lichen, is frequent in moors and heaths. It has in the first state a granulated crust for its ground, which is afterwards turned into small laciniated leaves, green above, and hoary underneath. The plant assumes a very different aspect, according to the age, situation, and other accidents of its growth; but may be in general readily distinguished by its fructifications, which are fungous tubercles of a fine scarlet colour, placed on the rim of the cup, or on the top of the stalk. These tubercles, steeped in an alcaline lixivium, are said to dye a fine durable red colour.

18. The rangiferinus, or rein-deer lichen, is frequent in woods, heaths, and mountainous places. Its general height, when full-grown, is about two inches. The stalk is hollow, and very much branched from bottom to top: the branches are divided and subdivided, and at last terminated by two, three, four, or five very fine, short, nodding horns. The axillæ of the branches are often perforated. The whole plant is of a hoary white or grey colour, covered with white farinaceous particles, slight and brittle when dry, soft and elastic when moist. The fructifications are very minute, round, fuscous, or reddish-brown tubercles, which grow on the very extremities of the finest branches; but these tubercles are very seldom found. The plant seems to have no foliaceous ground for the base, nor scarcely any visible roots. Linnæus tells us, that in Lapland this moss grows so luxuriant that it is sometimes found a foot high. There are many varieties of this species, of which the principal is the sylvaticus, or brown-tipt rein-deer lichen. The most remarkable difference between them is, that the sylvaticus turns fuscous by age, while the other always continues white.

19. The plicatus, or officinal stringy lichen, grows on the branches of old trees, but is not very common. The stalks are a foot or more in length, cylindrical, rigid, and string-shaped, very irregularly branched, the branches entangled together, of a cinereous or ash-colour, brittle and stringy if doubled short, otherwise tough and pliant, and hang pendant from the trees on which they grow. The shields grow generally at the extremities of the branches, are nearly flat, or slightly concave, thin, ash-coloured above, pale-brown underneath, and radiated with fine rigid fibres. As the plant grows old, the branches become covered with a white, rough, warty crust; but the young ones are destitute of it. It was formerly used in the shops as an astringent to stop hæmorrhages, and to cure ruptures; but is out of the modern practice. Linnæus informs us, that the Laplanders apply it to their feet to relieve the excoriations occasioned by much walking.

20. The barbatus, or bearded lichen, grows upon the branches of old trees in thick woods and pine-forests. The stalks or strings are slightly branched and pendulous, from half a foot to two feet in length, little bigger than a taylor's common sewing-thread; cylindrically jointed towards the base; but surrounded every where else with numerous horizontal capillary fibres, either simple or slightly branched. Their colour is a whitish green. This has an astringent quality like the preceding. When steeped in water, it acquires an orange colour; and, according to Dillenius, is used in Pennsylvania for dyeing that colour.

21. The vulpinus, or gold wiry lichen, grows upon the trunks of old trees, but is not very common. It is produced in erect tufts, from half an inch to two inches in height, of a fine yellow or lemon-colour, which readily discovers it. The filaments which compose it are not cylindrical, but a little compressed and uneven in the surface, variously branched, the angles obtuse, and the branches straggling and entangled one with another. Linnæus informs us, that the inhabitants of Smaland in Sweden dye their yarn of a yellow colour with this lichen; and that the Norwegians destroy wolves by stuffing dead carcases with this moss reduced to powder, and mixed with pounded glass, and so exposing them in the winter-season to be devoured by those animals.

LICONIA, in botany; a genus of the digynia order, belonging to the pentandria class of plants. There are five petals inlaid in the pit of the nectarium at its base; the capsule is bilocular and seed-bearing.

LICUALA, a genus of the nat. order of palmæ. The flowers are all hermaphrodite; cal. and cor. three-parted; nect. sertiform drupe. There is one species.

LIEUTENANTS, *Lords, of counties*, are officers who, upon any invasion or rebellion, have power to raise the militia, and to give commissions to colonels and other officers, to arm and form them into regiments, troops, and companies. Under the lords-lieutenants, are deputy-lieutenants, who have the same power; these are chosen by the lords-lieutenants, out of the principal gentlemen of each county, and presented to the king for his approbation.

LIFE ANNUITIES, annual payments, to continue during any given life or lives. The present value of a life annuity is the sum which would be sufficient (allowing for the chance of the life failing) to pay the annuity without loss; and supposing money to bear no interest, the value of an annuity of 1*l.* is equal to the expectation of the life. Thus it will be found by the table given under the article EXPECTATION OF LIFE, that the expectation of a life aged forty, is twenty-three years; or, in other words, that a set of lives at this age, will, one with another, enjoy twenty-three years each of existence, some of them enjoying a duration as much longer as others fall short of it. Therefore, supposing money to bear no interest, 23*l.* in hand for each life would be sufficient to pay to any number of such lives 1*l.* per annum, for their whole duration; or, in other words, 23*l.* is, on this supposition, the value of a life aged forty. But if any improvement is made of money by putting it out to interest, the sum just mentioned will be more than the value, because it will be more than sufficient to pay the annuity; and it will be as much more than sufficient as the improvement or the interest is greater. If, for instance, money may be so improved by being put out to interest, at 5*l.* per cent. as to double itself in fourteen years, the seller of such an annuity, on putting out *half* the purchase money to interest, will at the end of fourteen years find himself in possession of 20*l.* 10*s.* or of 11*l.* 10*s.* more than is sufficient to pay the remainder of the annuities, though he should make no further improvement of the purchase money. At whatever rate of interest the money is improved, there must be a surplus; and if it is fully improved at 5*l.* per cent., it will be found that 11*l.* 16*s.* 8*d.* for each annuity, will be sufficient (instead of 23*l.*) to make all the annual payments; or, if money can be improved at 6*l.* per cent., 10*l.* 14*s.* 1*d.* will be sufficient.

Many persons have fallen into an error with respect to the value of life-annuities, by considering it the same as the value of an annuity certain for a term of years equal to the expectation of the life. The inaccuracy of this mode of computation arises from the difference between the value of a certain number of payments to be made every year regularly till the term is completed, and the value of the same number of payments to be made at greater distances of time from one another, and not to be all made till many years after the expiration of the term equal to the expectation.

The true method of computing the values of life-annuities cannot be more clearly expressed than as it is given in "The Doctrine of Annuities and Assurances on Lives and Survivorships," by William Morgan.—"Was it *certain* that a person of a given age would live to the end of a year, the value of an annuity of 1*l.* on such a life would be the present sum that would increase in a year to the value of a life one year older, together with the value of the single payment of 1*l.* to be made at the end of a year; that is, it would be 1*l.* together with the value of a life aged one year older than the given life, multiplied by the value of 1*l.* payable at the end of a year. Call the value of a life one year older than the given life N, and the value of 1*l.*

payable at the end of a year $\frac{1}{r}$; then will the value of an annuity on the given life, on the supposition of a *certainty*, be $\frac{1}{r} + \frac{1}{r} \times N = \frac{1}{r} \times \overline{1 + N}$. But the fact is, that it is *uncertain* whether the given life will exist to the end of the year or not. this last value therefore, must be diminished in the proportion of this uncertainty; that is, it must be multiplied by the probability that the given life will survive one year, or supposing $\frac{b}{a}$ to express this probability, it will be $\frac{b}{ar} \times \overline{1 + N}$. In the same manner the values of annuities on the *joint continuance* of lives may be found: Call the value of any two joint lives M, the probability that two lives one year younger will exist a year $\frac{bd}{ac}$, and $\frac{1}{r}$ as above, the value of 1*l*., payable at the end of the year. Then, by reasoning as before, the value of the joint continuance of two lives one year younger will be expressed by $\frac{bd}{acr} \times \overline{1 + M}$."

By these theorems, tables may be calculated of the values of single or joint lives, according to any table of the probabilities of life, and by the use of logarithms, and computing upwards, from the oldest to the youngest life, the labour of forming such tables is not very great; few persons, however have occasion to undertake it, as the tables published by Dr. Price, Mr. Morgan, and Mr. Maseres, shew the values of life-annuities as accurately as the present knowledge of the decrements and duration of human life will admit, and are sufficient for almost every useful purpose.

TABLE I.

Shewing the Value of an Annuity of £.1 on a Single Life at every Age according to the probabilities of the duration of Human Life at Northampton, reckoning Interest at 5 per Cent.

Ages.	Value.	Age	Value.	Age.	Value.
Birth.	8.863	33	12.740	66	7.034

31	12.965	64	7.514		
32	12.854	65	7.276		

These values suppose the payments to be made *yearly*, and to begin at the end of the first year; if the payments are to be made *half-yearly*, the value in the table will be increased about one-fifth of a year's purchase.

In order to find the present value of an annuity during any given life, it is only necessary to multiply the value in the table corresponding with the age, by the given annuity.

Example. What should a person, aged 45, give, to purchase an annuity of 50*l*. during his life?

The value in the table against 45 years is 11.105, which multiplied by 50, gives the answer 555*l*. 5*s*.

TABLE II.

Shewing the Value of an Annuity during the joint contińuance of Two Lives, according to the probabilities of Life at Northampton; reckoning Interest at 5 per Cent.

Ages.	Value.	Ages.	Value.	Ages	Value.
5–5	11.984	20–25	10.989	40–45	8.643
5–10	12.315	20–30	10.707	40–50	8.177

15–80	3.372	35–80	3 268	85–85	1.256
20–20	11.232	40–40	9.016	90–90	0.909

It is unnecessary to insert a Table of the values of the longest of two lives, as it may be easily found from the values given in the above tables by the following general rules:

"From the sum of the values of the single lives subtract the value of an annuity on the joint lives, and the remainder will give the value of an annuity on the continuance of the longest of two such lives."

Example. What is the value of an annuity on the longest of two lives whose ages are thirty and forty?

By Table I. the value of a single life of 30 is 13.072, and by the same Table the value of a single life of 40 is 11.837. Their sum therefore is 24.909, from which 9 576 (the value of the joint lives of 30 and 40 by Table II.) being subtracted, gives 15.333 for the number of years purchase required.

The value of an annuity on three joint lives may be found from the preceding tables, by the following rule:

"Let A be the youngest, and C the oldest of the three proposed lives. Take the value of the two joint lives B and C, and find the age of a single life D of the same value. Then find the value of the joint lives A and D, which will be the answer."

Example. Let the three given lives be 20, 30, and 40. The value of the two oldest joint lives B and C will (by Table II.) be 9.576, answering in Table I. to a single life D of 54 years; and the value of the joint lives A and D, or the ages in the Table which come nearest to them, gives 8.216 for the value sought.

The value of three joint lives being known, the value of the longest of any three lives may be computed by the following rule:

"From the sum of the values of all the single lives, subtract the sum of the values of all the joint lives combined two and two. Then to the remainder add the value of the three joint lives; and this last sum will be the value of the longest of the three lives."

Example. The sum of the values of three single lives whose ages are 20, 30, and 40, is (by Table I.) 38.916. The value of two joint lives, whose ages are 20 and 30, is (by Table II.) 10.707; of two joint lives whose ages are 20 and 40, is 9.937, and two joint lives whose ages are 30 and 40 is 9.576; the sum of these three values is 30.220. This sum subtracted from 38.916, leaves 8.696, which remainder added to 8.216 (the value of the three joint lives in the last example), gives 16.912, the value of the longest of the three lives. The answers in this and the preceding example are not quite exact, in consequence of the table of joint lives being confined to the combinations of every fifth year of age; those who have occasion to make such computations, will find more extensive tables of the values of joint lives in Dr. Price's excellent Treatise on Reversionary Payments; but a general table of the values of two joint lives for every possible difference of age, at different rates of interest, has long been very desirable.

The solutions of the following Problems, in addition to the rules already given, will comprehend all the cases which most commonly occur relating to the values of annuities on lives or survivorship.

Prob. I. To detemine the value of an annuity on a given life for any number of years.

Solution. Find the value of a life as many years older than the given life as are equal to the term for which the annuity is proposed. Multiply this value by 1*l*., payable at the end of this term, and also by the probability that the life will continue so long. Subtract the product from the present value of the given life, and the remainder multiplied by the annuity will be the answer.

Example. Let the annuity be 20*l*. the age of the given life 35 years, and the term proposed 14 years. The value of a life aged 49 years (or 14 years older than the given life), appears by Table I. to be 10.443. The value of 1*l.* payable at the end of 14 years (see COMPOUND INTEREST), is .505068, and the probability that the life will exist so long, (See EXPECTATION OF LIFE) is $\frac{2936}{4010}$. These three values multiplied into each other are equal to 3.861, which being subtracted from 12.502 (the present value of the given life by Table I.), we have 8.641, and this remainder multiplied by 20, gives 162*l.* 16*s.* 4*d.* for the value required.

In a similar manner the value of an annuity for any given term, upon two joint lives, may be determined.

PROB. II. To find the value of an annuity certain for a given term after the extinction of any given life or lives.

Solution. Subtract the value of the life or lives from the perpetuity, and reserve the remainder. Then say, as the perpetuity, is to the present value of the annuity certain, so is the said reserved remainder, to a fourth proportional, which will be the number of years purchase required.

Example. A and his heirs are entitled to an annuity certain for 14 years, to commence at the death of B, aged 35. What is the present value of A's interest in this annuity?

By Table I. the value of the life of B is 12.502, which subtracted from 20, the perpetuity, leaves 7.498 for the remainder to be reserved. Then, as 20, is to 9.898 (the value of an annuity certain for 14 years), so is 7.498 (the reserved remainder), to 3.7107, the number of years purchase required.

PROB. III. To find the value of an annuity for a term certain, and also for what may happen to remain of a given life or lives after the expiration of this term.

Solution. Find the value of a life or lives as many years older than the given life or lives as are equal to the term for which the annuity certain is proposed. Multiply this value by 1*l.* payable at the end of the given term, and also by the probability that the given life or lives will continue so long. Add the product to the value of the annuity certain for the given term, and the sum will be the answer.

Example. Let the value be required of an annuity certain for 14 years, and also for the remainder of a life now aged 35 after the expiration of this term. By Table I. the value of a life aged 49 (or 14 years older than the given life) is 10.443. The value of 1*l.* payable at the end of 14 years, is .505068, and the probability that the life will exist so long is $\frac{2936}{4010}$. These three numbers multiplied into each other, produce 3.861, which being added to 9.898, the value of an annuity certain for 14 years (see ANNUITIES), becomes equal to 13.759, the number of years purchase required.

PROB. IV. To determine what annuity any given sum will purchase during the joint lives of two persons of given ages, and also during the life of the survivor, on condition that the annuity shall be reduced one-half at the extinction of the joint lives.

Solution. Let twice the given sum be divided by the sum of the two single lives, and the quotient will give the annuity to be paid during the joint lives; one-half of which is therefore the annuity to be paid during the remainder of the surviving life.

Example. A aged 27, and B aged 35, are desirous of sinking 1000*l.* in order to receive an annuity during their joint lives, and also another annuity of half the value during the remainder of the surviving life. It is required to determine what annuities should be granted them under those circumstances. By Table I. the value of a life of 27 is 13.377, and the value of a life of 35 is 12.502. 2000*l.* (or twice the given sum) being divided by 25.879 (the sum of the values of the two lives), gives 77.282*l.* for the annuity to be granted during the joint continuance of the lives; and its half, or 38.641*l.* is the annuity to be paid during the life of the survivor.

PROB. V. B, who is of a given age, will, if he lives till the decease of A, whose age is also given, become possessed of a perpetual annuity, or of an estate of a given yearly value; to find the worth of his expectation in present money.

Solution. Find the value of an annuity on two equal joint lives whose common age is equal to the age of the oldest of the two proposed lives, which value subtract from the perpetuity, and take half the remainder: then say, as the expectation of duration of the younger of the two lives, is to that of the older, so is the said half remainder, to a fourth proportional; which will be the number of years purchase required when the life of B in expectation is the older of the two: but if B be the younger, then add the value so found to that of the joint lives A and B, and let the sum be subtracted from the perpetuity, and you will also have the answer in this case.

Example. Suppose the age of B to be 30, and that of A 20 years, and the value of the estate 50*l.* per annum. Then the value of two equal joint lives, aged 30, is, by Table II. 10.255, and the perpetuity being 20, the difference will be 9.745, the half of which is 4.872. Therefore as 33.43, the expectation of A, is to 28.27, the expectation of B, so is 4.872, to 4.119, which being multiplied by 50, the given annuity, we have 205.95*l.* for the required value of B's expectation.

If the age of B had been 20, and that of A 30 years, then to 4.119, the value just found, add the value of the joint lives, which, by Table II. is 10.707, and the sum is 14.826, which subtracted from 20, the perpetuity, and the remainder multiplied by 50, gives 258.7*l.* for the required value in this case.

LIFE ESTATES are of two kinds, such as are created by the act of the parties, or such as are created by the operation of the law, as estates by curtesy or dower. 2 Black. 120.

Estates for life, created by deed or grant, are, where a lease is made of lands or tenements to a man, to hold for the term of his own life, or for that of another person, or for more lives than one; in any of which cases, he is called tenant for life: only when he holds the estate by the life of another, he is usually termed tenant pur auter vie, for another's life.

Estates for life may be created not only by the express terms before-mentioned, but also by a general grant, without defining or limiting any specific estate. 2 Black. 121.

If such persons, for whose life any estate shall be granted, shall absent themselves seven years, and no proof made of the lives of such persons, in any action commenced for the recovery of such tenements by the lessors or reversioners, the persons upon whose lives such estate depended, shall be accounted as dead; and the judges shall direct the jury to give their verdict as if the person absenting himself was dead. 19 Car. II. c. 6.

LIGAMENT. See ANATOMY.

LIGATURE. See SURGERY.

LIGHT. See OPTICS.

LIGHTS: stopping lights of any house is a nuisance, for which an action will lie, if the house is an antient house, and the lights antient lights: but stopping a prospect is not, being only matter of delight, not of necessity; and a person may have either an assize of nuisance against the persons erecting any such nuisance, or he may stand on his own ground and abate it. 2 Salk. 247.

LIGHTFOOTIA, a genus of the class and order polygamia dioecia. The cal. is four-leaved; cor. none; fem. and her. stigma sessile; berry umbilicated. There are three species, shrubs of the E. Indies.

LIGHTNING. See ELECTRICITY.

LIGUSTICUM, lovage; a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellatæ. The fruit is oblong, and quinquesulcated on each side; the florets are equal; the petals involuted or rolled inwards, and entire. There are eight species, of which the most remarkable are, the levisticum, or common, and the Scoticum, or Scots, lovage. The first is a native of the Appenine mountains in Italy. The second is a native of Scotland, and grows near the sea in various parts of the country.

The root of the first species agrees nearly in quality with that of angelica: the principal difference is, that the lovage-root has a stronger smell, and a somewhat less pungent taste, accompanied with a more durable sweetness, the seeds being rather warmer than the root; but although certainly capable of being applied to useful purposes, this root is not regarded in the present practice. The leaves of the second are sometimes eaten raw as a salad, or boiled as greens, by the inhabitants of the Hebrides. They give an infusion of the leaves in whey to calves, to purge them.

LIGUSTRUM, *privet*, a genus of the monogynia order, in the diandria class of plants; and in the natural method ranking under the 44th order, sepiariæ. The corolla is quadrifid; the berry tetraspermous. There are three species; of the common there are two varieties, the deciduous and the evergreen. They are hardy plants, rising from ten to fifteen feet high. They are easily propagated by seed, layers, suckers, or cuttings. They are used for making hedges. The purple colour upon cards is prepared from the berries. With the addition of alum, these berries are said to dye wool and silk of a good and durable green; for which purpose they must be gathered as soon as they are ripe. The leaves are bitter and slightly astringent. Oxen, goats, and sheep, eat the plant; horses refuse it.

LIKE, in geometry, &c. denotes the same with similar. See SIMILAR.

LILAC, in botany, a genus of trees, otherwise called syringa. See SYRINGA.

LILALITE. This stone appears to have been first observed by the abbé Poda, and to have been then described by De Born. Hitherto it has only been found in Moravia in Germany, and Sudermania in Sweden. There it is mixed with granite in large amorphous masses. It is composed of thin plates, easily separated, and not unlike those of mica. Not easily pulverised. Specific gravity 2.8549. Colour of the mass, violet-blue; of the thin plates, silvery white. Powder white, with a tint of red. Before the blowpipe, it froths, and melts easily into a white semitransparent enamel, full of bubbles. Dissolves in borax with effervescence, and communicates no colour to it. Effervesces slightly with soda, and melts into a mass spotted with red. With microcosmic salts it gives a pearl-coloured globule.

This stone was first called lilalite from its colour, that of the lily. Klaproth, who discovered its component parts, gave it the name of lepidolite.

It is composed of	53	silica
	20	alumina
	18	potass
	5	fluat of lime
	3	oxide of manganese
	1	oxide of iron
	100.	

LILIUM, the *lily*; a genus of the monogynia order, in the hexandria class of plants; and in the natural method ranking under the 10th order, coronariæ. The corolla is hexapetalous, and campanulated, with a longitudinal nectariferous line or furrow; the capsules connected by small cancellated hairs. There are eleven species; all of them bulbous-rooted, herbaceous, flowery perennials, rising with erect annual stalks three or four feet high, garnished with long narrow leaves, and terminated by fine clusters of large, bell-shaped, hexapetalous flowers of great beauty, of white, red, scarlet, orange, purple, and yellow colours.

All the species are propagated by sowing the seeds; and if care is taken to preserve these seeds from good flowers, very beautiful varieties are often produced.

The roots of the white lily are emollient, maturating, and suppurative, and are used externally in cataplasms for these purposes with success. The common form of applying them is, boiled and bruised. Gerard recommends them internally against dropsies.

The Kamtschatence, or Kamtschatka lily, called there saranne, makes a principal part of the food of Kamtschatkans. Its roots are gathered by the women in August, dried in the sun, and laid up for use: they are the best bread of the country; and after being baked are reduced to powder, and serve instead of flour in soups and several dishes. They are sometimes washed, and eaten as potatoes; are extremely nourishing, and have a pleasant bitter taste. Our navigators boiled and ate them with their meat. The natives often parboil, and beat it up with several sorts of berries, so as to form of it a very agreeable confection. Providentially it is an universal plant there, and all the grounds bloom with its flower during the season. Another happiness remarked there is, that while fish are scarce, the saranne is plentiful; and when there is a dearth of this, the rivers pour in their provisions with redoubled profusion. It is not to the labours of the females alone that the Kamtschatkans are indebted for these roots. A species of mouse saves them a great deal of trouble. The saranne forms part of the winter provisions of that little animal: they not only gather them in the proper season, and lay them up in their magazines, but at times have the instinct of bringing them out in sunny weather to dry them, lest they should decay. The natives search for their hoards; but with prudent tenderness leave part for the owners, being unwilling to suffer such useful caterers to perish.

LIMAX, the *slug*, or naked snail; a genus of insects belonging to the order of vermes mollusca. The body is oblong, fitted for crawling, with a kind of muscular coat on the upper part, and the belly is plain. They have four tentacula, or horns, situated above the mouth, which they extend or retract at pleasure. This reptile is always destitute of shell; but besides that its skin is more clammy, and of a greater consistency, than that of the snail, the black naked slug has a furrowed cloak, almost as thick and as hard as leather, under which it withdraws its head as within a shell. The head is distinguished from the breast by a black line. It is in its head and back that the snail-stone is found; which is a small pearled and sandy stone, of the nature of limestones: according to a popular opinion, it cures the tertian ague, if fastened to the patient's arm. These slugs move on slowly, leaving every where clammy and shining marks of their passage. They deposit their eggs in the earth. There are eight species, distinguished entirely by their colour; as the black slug, the white slug, the reddish slug, the ash-coloured slug, &c. The black slug is hermaphrodite. A black slug, powdered over with snuff, salt, or sugar, falls into convulsions, casts forth all its foam, and dies.

LIME, one of those earthy substances, which exist in every part of the known world. It is found purest in limestone, marble, and chalk. None of these substances are lime, but are capable of becoming so by burning in a white heat.

Lime may be also obtained perfectly pure by burning those crystallized limestones called calcareous spars, which are perfectly white and transparent, and also by burning some pure white marbles. It may be procured also in a state of purity by dissolving oyster-shells in muriatic acid, filtring the solution, mixing it with ammonia as long as a white powder continues to fall, and filtring again. The liquid is now to be mixed with a solution of carbonat of soda: the powder which falls being washed and dried, and heated violently in a platinum crucible, is pure lime.

Pure lime is of a white colour, moderately hard, but easily reduced to a powder. It has a hot burning taste, and in some measure corrodes and destroys the texture of those animal bodies to which it is applied. Its specific gravity is 2.3. It tinges vegetable blues green, and at last converts them to yellow.

If water be poured on newly burnt lime, it swells and falls to pieces, and is soon reduced to a very fine powder. In the mean time so much heat is produced, that part of the water flies off in vapour. If the quantity of lime slacked (as this process is termed) be great, the heat produced is sufficient to set fire to combustibles. In this manner, vessels loaded with lime have sometimes been burnt. When great quantities of lime are slacked in a dark place, not only heat but light also is emitted, as Mr. Pelletier has observed. When slacked lime is weighed, it is found to be heavier than it was before. This additional weight is owing to the combination of part of the water with the lime; which water may be separated again by the application of a red heat; and by this process the lime becomes just what it was before being slacked. Hence the reason of the heat evolved during the slacking of lime. Part of the water combines with the lime, and thus becomes solid; of course it parts with its caloric of fluidity, and probably also with a considerable quantity of caloric, which exists in water even when in the state of ice: for when two parts of lime and one part of ice (each at 32°) are mixed, they combine rapidly, and their temperature is elevated to 212°. The elevation of temperature during the slacking of barytes and strontian is owing to the same cause.

The smell perceived during the slacking of lime is owing to a part of that earth being elevated along with the vapour of the water; as evidently appears from this circumstance, that vegetable blues exposed to this vapour are converted to green.

Limestone and chalk, though they are capable of being converted into lime by burning, posesses hardly any of the properties of that active substance. They are tasteless, scarcely soluble in water, and do not perceptibly act on animal bodies. Now, to what are the new properties of lime owing? What alteration does it undergo in the fire?

It had been long known, that limestone loses a good deal of weight by being burned or calcined. It was natural to suppose, therefore, that something is separated from it during calcination. Dr. Black, of Edinburgh, published in 1756, those celebrated experiments on this subject, which form so brilliant an era in the history of chemistry. He first ascertained, that the quantity of water separated from limestone during its calcination is not nearly equal to the weight which it lost. He concluded in consequence, that it must have lost something else than mere water. What this could be, he was at first at a loss to conceive; but recollecting that Dr. Hales had proved, that limestone, during its solution in acids, emits a great quantity of air, he conjectured that this might probably be what it lost during calcination. He calcined it accordingly, and applied a pneumatic apparatus to receive the product. He found his conjecture verified; and that the air and water which separated from the lime were together precisely equal to the loss of weight which it had sustained. Lime, therefore, owes its new properties to the loss of air; and limestone differs from lime merely in being combined with a certain quantity of air: for he found that, by restoring again the same quantity of air to lime, it was converted into limestone. This air, because it existed in lime in a fixed state, he called fixed air. It was afterwards examined by Dr. Priestley and other philosophers; found to possess peculiar properties, and to be that species of gas now known by the name of carbonic acid gas. Lime then is a simple substance, and limestone is composed of carbonic acid and lime. Heat separates the carbonic acid, and leaves the lime in a state of purity. See Air.

When lime is exposed to the open air, it gradually attracts moisture, and falls to powder; after which it soon becomes saturated with carbonic acid, and is again converted into carbonat of lime or unburnt limestone.

Water, at the common temperature of the atmosphere, dissolves about 0.002 parts of its weight of lime. This solution is called lime-water. It is limpid, has an acrid taste, and changes vegetable blue colours to green. One ounce troy of lime-water contains about one grain of lime. It is usually formed by throwing a quantity of lime in powder into pure water, allowing it to remain for some time in a close vessel, and then decanting the transparent solution from the undissolved lime. When lime-water is exposed to the air, a stony crust soon forms on its surface, composed of carbonat of lime; when this crust is broken it falls to the bottom and another succeeds it; and in this manner the whole of the lime is soon precipitated, by absorbing carbonic acid from the air.

Lime is not acted on by light, neither does it combine with oxygen. Sulphur and phosphorus are the only simple combustibles with which it unites.

Sulphuret of lime may be formed by mixing its two component parts, reduced to a powder, and heating them in a crucible. They undergo a commencement of fusion, and form an acrid taste. When it is exposed to the air, or moistened with water, its colour becoming greenish-yellow, sulphureted hydrogen is formed, and the sulphuret is converted into a hydrogenated sulphuret, which exhales a very fetid odour of sulphureted hydrogen gas. This hydrogenated sulphuret may be formed also by boiling a mixture of lime and sulphur in about ten times its weight of water, or by sprinkling quicklime with sulphur and then moistening it: the heat occasioned by the slacking of the lime is sufficient to form the combination. When this hydrogenated sulphuret is exposed to the air, it imbibes oxygen; which combines at first with the hydrogen, and afterwards with the sulphur, and converts the compound into sulphat of lime.

Phosphuret of lime may be formed by the following process: put into the bottom of a glass tube, close at one end, one part of phosphorus; and, holding the tube horizontally, introduce five parts of lime in small lumps, so that they shall be about two inches above the phosphorus. Then place the tube horizontally among burning coals, so that the part of it which contains the lime may be made red-hot, while the bottom of the tube containing the phosphorus remains cold. When the lime becomes red-hot, raise the tube, and draw it along the coals till that part of it which contains the phosphorus is exposed to a red heat. The phosphorus is immediately volatilized, and passing through the hot lime combines with it. During the combination the mass becomes of a glowing red heat, and a quantity of phosphurated hydrogen gas is emitted, which takes fire when it comes into the air.

Lime does not combine with azote; but it unites readily with muriatic acid, and forms muriat of lime. It facilitates the oxidizement of several of the metals, and it combines with several of the metallic oxides, and forms salts which have not hitherto been examined, if we except the compounds which it forms with the oxides of mercury and lead, which have been described by Berthollet.

The red oxide of mercury, boiled with lime-water, is partly dissolved, and the solution yields by evaporation small transparent yellow crystals. This compound has been called by some mercuriat of lime.

Lime-water also dissolves the red oxide of lead, and (still better) litharge. This solution, evaporated in a retort, gives very small transparent crystals, forming prismatic colours, and not more soluble in water than lime. It is decomposed by all the alkaline sulphats, and by sulphureted hydrogen gas. The sulphuric and muriatic acids precipitate the lead. This compound blackens wool, the nails, the hair, and white of eggs; but it does not affect the colour of silk, the skin, the yolk of egg, nor animal oil. It is the lead which is precipitated on these coloured substances in the state of oxide; for all acids can dissolve it. The simple mixture of lime and oxide of lead blackens these substances; a proof that the salt is easily formed.

Lime does not combine with alkalies. The affinities of lime are arranged by Bergman in the following order:

Oxalic acid	Arsenic
Sulphuric	Lactic
Tartaric	Citric
Succinic	Benzoic
Phosphoric	Sulphurous
Saclactic	Acetic
Nitric	Boracic
Muriatic	Carbonic
Suberic	Prussic
Fluoric	

One of the most important uses of lime is, in the formation of mortar as a cement in building. Mortar is composed of quicklime and sand reduced to a paste with water. When dry it becomes as hard as stone, and as durable; and adhering very strongly to the surfaces of the stones which it is employed to cement, the whole wall becomes in fact nothing else than one single stone. But this effect is produced very imperfectly unless the mortar is very well prepared.

The lime ought to be pure, completely free from carbonic acid, and in the state of a very fine powder: the sand should be free from clay, and partly in the state of fine sand, partly in that of gravel: the water should be pure; and if previously saturated with lime, so much the better. The best proportions, according to the experiments of Dr. Higgins, are three parts of fine sand, four parts of coarse sand, one part of quicklime recently slacked, and as little water as possible.

The stony consistence which mortar acquires, is owing partly to the absorption of carbonic acid, but principally to the combination of part of the water with the lime. This last circumstance is the reason that if to common mortar one-fourth part of lime, reduced to powder without being slacked, is added, the mortar, when dry, acquires much greater solidity than it otherwise would do. This was first proposed by Loriot; and a number of experiments were afterwards made by Morveau. The proportions which this philosopher found to answer best are the following:

Fine sand - -	0.3
Cement of well-baked bricks	0.3
Slacked lime - -	0.2
Unslacked lime - -	0.2
	1.0

The same advantages may be attained by using as little water as possible in slacking the lime.

Higgins found that the addition of burnt bones improved mortar by giving it tenacity, and rendering it less apt to crack in drying; but they ought never to exceed one-fourth of the lime employed.

When a little manganese is added to mortar, it acquires the important property of hardening under water; so that it may be employed in constructing those edifices which are constantly exposed to the action of water. Limestone is often combined with manganese: in that case it becomes brown by calcination.

LIMESTONE. See Salts, *calcareous*.

Limestone, *primitive* and *secondary*. See Rocks.

LIMEUM, a genus of the class and order heptandria digynia. The cal. is five-leaved; pet. five, equal; caps. globular, two-celled. There are three species, herbaceous plants of the Cape.

LIMIT, in a restrained sense, is used by mathematicians for a determinate quantity to which a variable one continually approaches; in which sense the circle may be said to be the limit of its circumscribed and inscribed polygons. In algebra, the term limits is applied to two quantities, one of which is greater, and the other less, than another quantity; and in this sense it is used in speaking of the limits of equations, whereby their solution is much facilitated.

Let any equation, as $x^3 - px^2 \times qx - r = 0$ be proposed; and transform it into the following equation:

$$\left.\begin{array}{r} y^3 + 3ey^2 + 3e^2y + e^3 \\ - py^2 - 2pey - pe^2 \\ + qy + qe \\ - r \end{array}\right\} = 0,$$

where the values of y are less than the respective values of x, by the difference e. If you suppose e to be taken such as to make all the co-efficients of the equation of y positive, viz. $e^3 - pe^2 + qe - r$, $3e^2 - 2pe + q$, $3e - p$; then there being no variation of the signs in the equation, all the values of y must be negative; and consequently the quantity e, by which the values of x are diminished, must be greater than the greatest positive value of x: and, consequently, must be the limit of the roots of the equation $x^3 - px^2 + qx - r = 0$.

It is sufficient, therefore, in order to find the limit, to enquire what quantity substituted for x, in each of these expressions $x^3 - px^2 + qx - r$, $3x^2 - 2px + q$, $3x - p$, will give them all positive; for the quantity will be the limit required.

Having found the limit that surpasses the greatest positive root, call it m. And if you assume $y = m - x$, and for x substitute $m - y$, the equation that will arise will have all its roots positive; because m is supposed to surpass all the values of x, and consequently $m - x$ ($= y$) must always be affirmative. And, by this means, any equation may be changed into one that shall have all its roots affirmative.

Or, if $-n$ represent the limit of the negative roots, then by assuming $y = x + n$, the proposed equation shall be transformed into one that shall have all its roots affirmative; for, $+n$ being greater than any negative value of x, it follows that $y = x - n$ must be always positive.

What is here said of the above cubic equation, may be easily applied to others; and of all such equations, two limits are easily discovered, viz. o, which is less than the least; and e, found as above, which surpasses the greatest root of the equation. But besides these, other limits still nearer the roots may be found; for the method of doing which, the reader may consult Maclaurin's Algebra.

LIMITATION, a certain time prescribed by statute, within which an action must be brought. The time of limitation is twofold; first in writs, by divers acts of parliament; secondly to make a title to any inheritance, and that is by the common law.

Limitation on penal statutes.—All actions, suits, bills, indictments, or informations, which shall be brought for any forfeiture upon any statute penal, made or to be made, whereby the forfeiture is or shall be limited to the queen, her heirs or successors only, shall be brought within two years after the offence committed, and not after two years; and all actions, suits, bills, or informations, which shall be brought for any forfeiture upon any penal statute, made or to be made, except the statutes of tillage, the benefit and suit whereof is or shall be by the said statute limited to the queen, her heirs or successors, and to any other that shall prosecute in that behalf, shall be brought by any person that may lawfully sue for the same, within one year next after the offence committed; and in default of such pursuit, then the same shall be brought for the queen's majesty, her heirs or successors, any time within the two years, after that year is ended: and it is provided, that where a shorter time is limited by any penal statute, the prosecution must be within that time. 31 Eliz. c. 5.

Limitation in regard to personal actions of assault and battery, and actions arising upon contract and trespass.

All actions of trespass, of assault, battery, wounding, imprisonment, or any of them, shall be commenced and sued within four years next after the cause of such actions or suits, and not after. 21 Jac. I. c. 16.

Actions of account, &c.—All actions of trespass quare clausum fregit, all actions of trespass, detinue, trover, and replevin, all actions of account, and upon the case (other than such accounts as concern the trade of merchandize, between merchant and merchant), all actions of debt grounded upon any lending, or contract without specialty, (that is, not being by deed or under seal) all actions of debt for arrearages of rent, and all actions of assault, menace, battery, wounding, and imprisonment, shall be commenced within the time and limitation as followeth, and not after; that is to say, the said actions upon the case (other than for slander), and the said actions for trespass, debt, detinue, and replevin, and the said actions for trespass, debt, detinue, and replevin, and the said acts for trespass quare clausum fregit, within six years, after the cause of such action. 21 Jac. c. 16.

Exception in relation to infants.—It has been holden, that if an infant during his infancy, by his guardian bring an action, the defendant cannot plead the statute of limitation, although the cause of action accrued six years before; and the words of the statute are, that after his coming of age, &c.

Exception in relation to merchants' accounts.—As to this exception, it has been matter of much controversy, whether it extends to all actions and accounts relating to merchants and merchandize, or to actions of account open and current only. But it is now settled, that accounts open and current only are within the statute; and that therefore, if an account be stated and settled between merchant and merchant, and a sum certain agreed to be due to one of them, if in such case, he to whom the money is due, do not bring his action within the limited time, he is barred by the statute. 2 Mod. 312.

Exception in relation to persons beyond sea.—It seems to have been agreed that the exception as to persons being beyond sea, extends only where the creditors or plaintiffs are so absent, and not to debtors or defendants, because the first only are mentioned in the statute; and this construction has the rather prevailed, because it was reputed the creditor's folly, that he did not file an original, and outlaw the debtor, which would have prevented the bar of the statutes.

Executor or administrator.—If A receives money belonging to a person who afterwards died intestate, and to whom B takes out administration, and brings an action against A, to which he pleads the statute of limitations, and the plaintiff replies, and shews that administration was committed to him such a year, which was within six years; though six years are expired since the receipt of the money, yet not being so since the administration committed, the action is not barred by the statute. 1 Salk. 421.

Where a debt barred by the statute shall be revived.—Any acknowledgment of the existence of the debt, however slight, will take it out of the statute, and the limitation will then run from that time: and where an expression is ambiguous, it shall be left to the consideration of the jury, whether it amounts or not to such acknowledgment. 2 Durnf. & East, 760.

It is clearly agreed, that if after the six years, the debtor acknowledges the debt, and promise payment, that this revives it, and brings it out of the statute: as if a debtor by promissory note, or simple contract, promises within six years of the action brought, that he will pay the debt; though this was barred by the statute, yet it is revived by the promise; for as the note itself was at first but an evidence of the debt, so that being barred the acknowledgment and promise is a new evidence of the debt, and being proved, will maintain an assumpsit for recovery of it. 1 Salk. 28.

LIMITS of a planet, its greatest excursion from the ecliptic, or which is the same thing, the points of its greatest latitude.

LIMITED PROBLEM, a problem that admits but of one solution, as to make a circle pass through three given points, not lying in the same right line.

LIMOSELLA, a genus of the didynamia angiospermia class of plants: the flower consists of one erect petal, divided into five segments; fruit is an unilocular capsule, with a great many seeds. Two species, annuals of the Cape.

LIMODORUM, a genus of the gynandria diandria class of plants, the flower of which consists of five oblong petals, and the nectarium hollow, and formed of a single leaf: the fruit is a columnar unilocular capsule, containing a great number of very small seeds. There are thirteen species, bulbs of America, &c.

LIMONIA, a genus of the decandria monogynia class and order. The cal. is five-parted; pet. five-berry, three-celled. Seeds solitary. There are seven species, trees of the East Indies, &c.

LINCONIA, a genus of the class and order pentandria digynia. The pet. are five; caps. two-celled. There is one species, a shrub of the Cape.

LINDERA, a genus of the class and order hexandria monogynia. The cor. is six-petalled; caps. There is one species, a shrub of Japan.

LINDERNIA, a genus of the class and order didynamia angiospermia. The cal. is five-parted; caps. one-celled. There are three species, annuals of America.

LINE, in geometry, a quantity extended in length only, without any breadth or thickness. It is formed by the flux or motion of a point: see FLUXION, and GEOMETRY. Right lines are all of the same species, but curves are of an infinite number of different species. We may conceive as many as there may be different ratios between their ordinates and abscisses.

Curve lines are usually divided into geometrical and mechanical; the former are those which may be found exactly in all their points; the latter are those, some or all of whose points are not to be found precisely, but only tentatively, or nearly.

Curve lines are also divided into the first order, second order, third order, &c. See CURVE.

Lines considered as to their positions, are either parallel, perpendicular, or oblique, the construction and properties whereof see under PARALLEL, &c.

Euclid's second book treats mostly of lines, and of the effects of their being divided and again multiplied into one another.

LINES, in perspective, are, 1. Geometrical line, which is a right line drawn in any manner on the geometrical plane. 2. Terrestrial line, or fundamental line, is a right line wherein the geometrical plane, and that of the picture or draught, intersect one another. See PERSPECTIVE.

LINES. See DIALLING.

LINE of direction on the earth's axis, in the Pythagorean system of astronomy, the line connecting the two poles of the ecliptic and of the equator, when they are projected on the plane of the former.

LINE of direction. See MECHANICS.

LINE of gravitation of any heavy body, a line drawn through its centre of gravity, and according to which it tends downwards.

LINE of the swiftest descent of a heavy body, is the cycloid. See CYCLOID.

LINES on the plain scale, are the line of chords, line of sines, line of tangents, line of secants, line of semitangents, line of leagues; the construction and application of which see under the words SCALE, SAILING, INSTRUMENTS, &c.

LINES on Gunter's scale. See GUNTER'S SCALE.

LINES of the sector. See INSTRUMENTS.

LINES, in fortification, are those of approach, capital, defence, circumvallation, contravallation of the base, &c.

To LINE a work, signifies to strengthen a rampart with a firm wall; or to encompass a parapet or moat with good turf, &c.

LINE, in the art of war, is understood of the disposition of an army, ranged in order of battle, with the front extended as far as may be, that it may not be flanked.

LINE of battle, is also understood of the disposition of a fleet on the day of engagement.

Ship of the LINE, a vessel large enough to be drawn up in the line, and to have a place in a sea-fight.

LINE, also denotes a French measure, containing the twelfth part of an inch, or the hundred and forty-fourth part of a foot. Geometricians conceive the line subdivided into six points. The French line answers to the English barleycorn.

LINEAR NUMBERS, in mathematics, such as have relation to length only; such is a number which represents one side of a plane figure. If the plane figure be a square, the linear number is called a root.

LINEAR PROBLEM, that which may be solved geometrically, by the intersection of two right lines. This is called a simple problem, and is capable but of one solution.

LINEN, in commerce, a well-known kind of cloth, chiefly made of flax. See LINUM, and WEAVING.

LING. See GADUS.

LINIMENT. See PHARMACY.

LINNÆA, a genus of the class and order didynamia angiospermia. The cal. is double; the cor. bell-shaped; the berry dry, three-celled. There is one species, a herb of Sweden.

LINNET. See FRINGILLIA.

LINSEED, the seed of the plant linum. See LINUM.

LINSPINS, in the military art, small pins of iron, which keep the wheel of a cannon or waggon on the axletree; for when the end of the axletree is put through he nave, the linspin is put in, to keep the wheel from falling off.

LINT, the scrapings of linen; which is used in dressing wounds, and is made up in various forms, as tents, dossils, pledgets, &c. See SURGERY.

LINUM, FLAX; a genus of the pentagynia order, in the pentandria class of plants; and in the natural method ranking under the 14th order, gruinales. The calyx is pentaphyllous; the petals are five; the capsule is quinquevalved and decemlocular; and the seeds are solitary. There are 25 species, of which the most remarkable are,

1. The usitatissimum, or common annual flax. 2. The perenne, or perennial Siberian flax, with umbellate clusters of large blue flowers. 3. The catharticum, or purging flax, a very small plant, not above four or five inches high; found wild upon chalky hills and in dry pleasure-grounds.

The first species is cultivated in the fields for the use of the manufacturers. The second sort is chiefly ornamental. The virtue of the third species is expressed in its title: an infusion in water or whey of a handful of the fresh leaves, or a dram of them in substance when dried, is said to purge without inconvenience.

Of the cultivation of flax. A skilful flax-raiser always prefers a free, open, deep loam; and all grounds that produced the preceding year a good crop of turnips, cabbages, potatoes, barley, or broad clover; or have been formerly laid down rich, and kept for some years in pasture.

If the linseed is sown early, and the flax not allowed to stand for seed, a crop of turnips may be got after the flax that very year; the second year a crop of rye or barley may be taken; and the third year, grass-seeds are sometimes sown along with the linseed. Of preceding crops, potatoes and hemp are the best preparation for flax. If the ground is free and open, it should be but once ploughed, and that as shallow as possible, not deeper than two and a half inches. It should be laid flat, reduced to a fine garden mould by good harrowing, and all stones and sods should be carried off. Except a little pigeon's dung for cold or sour ground, no other dung should be used preparatory for flax; because it produces too many weeds, and throws up the flax thin and poor upon the stalk. Before sowing, the bulky clods should be broken, or carried off the ground; and stones, quickenings, and every other thing that may hinder the growth of the flax, should be carefully taken away. The brighter in colour, and heavier the seed is, so much the better; that which when bruised appears of a light or yellowish green, and fresh in the heart, oily, and not dry, and smells and tastes sweet, and not fusty, may be depended upon. Dutch seed of the preceding year's growth, for the most part, answers best; but it seldom succeeds if kept another year. It ripens sooner than any other foreign seed. Philadelphia seed produces fine lint and few bolls, because sown thick, and answers best in wet cold soils.

The quantity of linseed sown should be proportioned to the condition of the soil; for if the ground is in good heart, and the seed sown thick, the crop will be in danger of falling before it is ready for pulling. The time for sowing linseed is from the middle of March to the end of April, as the ground and season answer; but the earlier the seed is sown, the less the crop interferes with the corn harvest. Late-sown linseed may grow long, but the flax upon the stalk will be thin and poor.

Flax ought to be weeded, when the crop is about four inches long. If longer deferred, the weeders will also much break and bend the stalks, and they will perhaps never recover their straightness again; and when the flax grows crooked, it is more liable to be hurt in the rippling and swingling. Quicken grass should be taken up; for, being strongly rooted, the pulling of it always loosens a great deal of the lint. If there is an appearance of a settled drought, it is better to defer the weeding, than by that operation to expose the tender roots of the flax to the drought.

When the crop grows so short and branchy as to appear more seed than flax, it ought not to be pulled before it is thoroughly ripe; but if it grows long and not branchy, the seed should be disregarded, and all the attention given to the flax. In the last case it ought to be pulled after the bloom has fallen, when the stalk begins to turn yellow, and before the leaves fall, and the bolls turn hard and sharp-pointed. When the stalk is small, and carries few bolls, the flax is fine; but the stalk of coarse flax is gross, rank, branchy, and carries many bolls. When the flax has fallen, and lies, such as lies ought to be immediately pulled, whether it has grown enough or not, as otherwise it will rot altogether. When parts of the same field grow unequally, so that some parts are ready for pulling before other parts, only what is ready should be pulled, and the rest should be suffered to stand till it ripens. The flax-raiser ought to be at pains to pull and keep by itself, each different kind of lint which he finds in his field; what is both long and fine, by itself; what is both long and coarse, by itself; what is both short and fine, by itself; what is both short and coarse by itself; and in like manner every other kind by itself that is of the same size and quality.

If the flax is more valuable than the seed, it ought by no means to be stacked up; for its own natural juice assists it greatly in the watering; whereas, if kept long unwatered, it loses that juice, and the harle adheres so much to the boon, that it requires longer time to water, and even the quality of the flax becomes harsher and coarser. Besides, the flax stacked up is in great danger from vermin and other accidents; the water in spring is not so soft and warm as in harvest; and near a year is lost of the use of the lint; but if the flax is so short and branchy as to appear most valuable for seed, it ought, after pulling, to be stacked and dried upon the field, as is done with corn; then stacked up for winter, rippled in spring; and the seed should be well cleaned from bad seeds, &c.

If the flax is to be regarded more than the seed, it should, after pulling, be allowed to lie some hours upon the ground to dry a little, and so gain some firmness, to prevent the skin or harle, which is the flax, from rubbing off in the rippling; an operation which ought by no means to be neglected, as the bolls, if put into the water along with the flax, breed vermin there, and otherwise spoil the water. The bolls also prove very inconvenient in the grassing and breaking. The handfuls for rippling should not be great, as that endangers the lint in the rippling comb. After rippling, the flax-raiser will perceive, that he is able to assort each size and quality of the flax by itself more exactly than he could before.

In watering, a running stream wastes the lint, makes it white, and frequently carries it away. Lochs, by the great quantity and motion of the water, also waste and whiten the flax, though not so much as running streams. Both rivers and lochs water the flax quicker than canals. The greater way the river or brook has run, the softer, and therefore the better, will the water be. Springs, or short runs from hills, are too cold, unless the water is allowed to stand long in the canal. Water from coal or iron is very bad for flax. A little of the powder of galls thrown into a glass of water will discover if it comes from minerals of that kind, by turning it into a dark colour, more or less tinged in proportion to the quantity of metal it contains. When the water is brought to a proper heat, small plants will be rising quickly in it, numbers of small insects and reptiles will be generating there, and bubbles of air rising on the surface. If no such signs appear, the water is scarcely warm enough, or is otherwise unfit for flax. Moss-holes, when neither too deep nor too shallow, frequently answer well for watering flax, when the water is proper, as before described. The proper season for watering flax is from the end of July to the end of August. The doing this as soon as possible after pulling is very advantageous. The flax being sorted after rippling, as before mentioned, should next be put in beets, never larger than a man can grasp with both his hands, and tied very slack with a band of a few stalks. Dried rushes answer exceedingly well for binding flax, as they do not rot in the water, and may be dried and kept for use again. The beets should be put into the canals slope-ways, or half-standing upon end, the root end uppermost. Upon the crop ends, when uppermost, vermin frequently breed, destructive of the flax, which are effectually prevented by putting the crop end downmost. The whole flax in the canal ought to be carefully covered from the sun with divots; the grassy side of which should be next the flax, to keep it clean. If it is not thus covered, the sun will discolour the flax, though quite covered with water. If the divots are not weighty enough to keep the flax entirely under water, a few stones might be laid above them; but the flax should not be pressed to the bottom.

When the flax is sufficiently watered, it feels soft to the gripe, and the harle parts easily with the boon or show, which last is then become brittle, and looks whitish. When these signs are found, the flax should be taken out of the water, beet after beet; each gently rinsed in the water, to cleanse it of the filth which has gathered about it in the canal; and as the lint is then very tender, and the beet slackly tied, it must be carefully and gently handled. Great care ought to be taken that no part be overdone: and as the coarsest waters soonest, if different kinds are mixed together, a part will be rotted, when the rest is not sufficiently watered. When lint taken out of the canal is not found sufficiently watered, it may be laid in a heap for twelve, eighteen, or twenty-four hours, which will have an effect like more watering; but this operation is nice, and may prove dangerous in unskilful hands. After the flax is taken out of the canal, fresh lint should not be put a second time into it, until the former water is run off, and the canal cleaned, and supplied with a fresh quantity of water.

Short heath is the best field for grassing flax; as, when wet, it fastens to the heath, and is thereby prevented from being blown away by the wind. The heath also keeps it a little above the earth, and so exposes it more equally to the weather. When such heath is not to be got, links or clean old lea-ground is the next best. Long-grass grounds should be avoided, as the grass growing through the lint frequently spots, tenders, or rots it; and grounds exposed to violent winds should also be avoided. The flax, when taken out of the water, must be spread very thin upon the ground; and being then very tender, it must be gently handled. The thinner it is spread the better, as it is then more equally exposed to the weather. But it ought never to be spread during a heavy shower, as that would wash and waste the harle too much, which is then excessively tender, but soon after becomes firm enough to bear the rains, which, with the open air and sunshine, cleans, softens, and purifies the harle to the degree wanted, and makes it blister from the boon. In short, after the flax has got a little firmness by being a few hours spread in dry weather, the more rain and sunshine it gets the better. If there is little danger of high winds carrying off the flax, it will be much the better for being turned about once a week. If it is not to be turned, it ought to be very thin spread. The spreading of flax and hemp, which requires a great deal of ground, enriches it greatly. The flax-raiser should spread his first row of flax at the end of the field opposite to the point whence the most violent wind commonly comes, placing the root ends foremost. He makes the root ends of every other row overlap the crop ends of the former row three or four inches, and binds down the last row with a rope; by which means the wind does not easily get below the lint to blow it away; and as the crop ends are seldom so fully watered as the root ends, the overlapping has an effect like giving the crop ends more watering.

A dry day ought to be chosen for taking up the flax; and if there is no appearance of high wind, it should be loosed from the heath or grass, and left loose for some hours, to make it thoroughly dry.

As a great quantity of flax can scarcely be all equally watered and grassed, and as the different qualities will best appear at lifting the flax off the grass; therefore at that time each different kind should be gathered together, and kept by itself; that is, all of the same colour, length, and quality.

The smaller the beets lint is made up in, the better for drying, and the more convenient for stacking, housing, &c. and in making up these beets, as in every other operation upon flax, it is of great consequence that the lint be laid together as it grew, the root ends together, and the crop ends together. The profit on five acres of flax raised in Shropshire, was 46*l*. 4*s*. 5*d*.

LION. See FELIS.

LIPARIA, a genus of the diadelphia decandria class and order. The cal. is five-cleft; cor. wings two-lobed, below; stam. the larger, with three shorter teeth; legume ovate. There are four species, shrubs of the Cape.

LIPPIA, a genus of the didynamia gymnospermia class and order. The cal. is four-toothed; the caps. one-celled, three-valved, two-seeded; seed one, two-celled. There are five species, shrubs of America.

LIQUEFACTION. See FLUIDITY.

LIQUIDS, expansion of. See EXPANSION.

LIQUIDAMBAR, SWEET-GUM TREE, a genus of the polyandria order, in the monœcia class of plants; and in the natural method ranking with those of which the order is doubtful. The male calyx is common and triphyllous; there is no corolla, but numerous filaments; the male calyces are collected into a spherical form, and tetraphyllous; there is no corolla; but seven styles, and many bivalved and monospermous capsules, collected into a sphere. There are only two species, both deciduous, viz. 1. The styraciflua, or the Virginia or maple-leaved liquidambar; a native of the rich moist parts of Virginia and Mexico. It will shoot in a regular manner to thirty or forty feet high, having its young twigs covered with a smooth light-brown bark, while those of the older are of a darker colour. The flowers are of a kind of saffron-colour: they are produced at the ends of the branches the beginning of April, and sometimes sooner; and are succeeded by large round brown fruit, which looks singular, but is thought by many to be no ornament to the tree. 2. The peregrinum, Canada liquidambar, or spleenwort-leaved gale, is a native of Canada and Pennsylvania. The young branches of this species are slender, tough, and hardy. The flowers come out from the sides of the branches, like the former; and they are succeeded by small roundish fruit, which seldom ripens in England. These may be propagated either by seeds or layers.

The leaves of this tree emit their odoriferous particles in such plenty as to perfume the circumambient air; nay, the whole tree exudes such a fragrant transparent resin, as to have given occasion to its being taken for the sweet storax. (See STYRAX.) These trees, therefore, are very proper to be planted singly in large opens, that they may amply display their fine pyramidal growth, or to be set in places near seats, pavilions, &c. The resin was formerly of great use as a perfume, and is at present no stranger in the shops.

LIQUORICE. See GLYCIRRHIZA, and MATERIA MEDICA.

LIRIODENDRON, the TULIP-TREE, a genus of the polygynia order, in the polyandria class of plants; and in the natural method ranking under the 52d order, coadunatæ. The calyx is triphyllous; there are nine petals; and the seeds imbricated in such a manner as to form a cone. There are two species; the tulipfera, is best known here, and is a deciduous tree, native of most part of America. It rises with a large upright trunk, branching forty or fifty feet high. The trunk, which often attains to a circumference of thirty feet high, is covered with a grey bark. The leaves grow irregularly on the branches, on long footstalks. They are of a particular structure, being composed of three lobes, the middlemost of which is shortened in such a manner that it appears as if it had been cut off and hollowed at the middle. The two others are rounded off. They are about four or five inches long, and as many broad. The flowers are produced with us in July, at the ends of the branches. The number of petals of which each is composed, like those of the tulip, is six; and these are spotted with green, red, white, and yellow. The flowers are succeeded by large cones, which never ripen in England.

LISIANTHUS, a genus of the pentandria monogynia class and order. The cal. is keeled; cor. with ventricose tube and recurved division; stigma two-plated; caps. two-valved, two-celled. There are 9 species, herbs of the West Indies.

LITA, a genus of the class and order pentandria monogynia. The cal. is five-cleft; cor. salver-shaped, long tube, five-cleft; caps. one-celled, two-valved; seeds numerous. There are two species, herbs of Guiana.

LITHOPHILA, a genus of the diandria monogynia class and order. The cal. is three-leaved; cor. three-petalled; nect. two-leaved. There is one species, of no note.

LITHARGE, an oxide of lead. See LEAD.

LITHOPHYTA, the name of Linnæus's third order of vermes.

LITHOSPERMUM, GROMWELL: a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 41st order, asperifoliæ. The corolla is funnel-shaped, with the throat perforated and naked; the calyx quinquepartite. There are 12 species; but the only remarkable ones are the officinale or common gromwell, and the arvense or bastard alkanet. Both these are natives of Britain; the former growing in dry gravelly soil, the latter in corn-fields.

LITHOTOMY. See SURGERY.

LITTORELLA, a genus of the monœcia tetrandria class and order. The male cal. is four-leaved; cor. four-cleft; stam. long. No female cal.; cor. four-cleft; seed a nut. There is one species.

LIVER. See ANATOMY.

LIVERY *of seisin*, in law, signifies delivering the possession of lands, &c. to him who has a right to them. There are two kinds of livery and seisin; livery in law, where the feoffer being in view of the land, house, or other thing granted, says to the feoffee, on delivery of the deed, "I give to you yonder land, &c. to hold to you and to your heirs, so go into the same, and take possession accordingly." And livery in deed, is where the parties, or the attorneys by them authorised, coming to the door of the house, or upon some part of the land, declare the occasion of their meeting before witnesses, read the deed, or its contents, and in case it be made by attorney, the letter of attorney is also read, after which, if the delivery is of a house, the grantor, or his attorney, takes the ring, key, or latch belonging to the door, or if it be a land, a turf, or clod of earth, and a twig of one of the trees, and delivering them with the deed to the grantee or his attorney, says, "I A. B. do hereby deliver to you possession and seisin of this message or tenement, &c. to hold to you, your heirs and assigns, according to the purport, true intent, and meaning of this indenture, or deed of feoffment." After which the grantee enters first alone, and shutting the door, and then opening it, lets in others.

Since the making the statute of uses, livery and seisin are not so much used as formerly; for a lease and release, a bargain and sale by deed inrolled, are sufficient to vest the grantee with possession, without the formality of livery.

LIVERYMEN of London, are a number of men selected from among the freemen of each company. Out of this body, the common council, sheriff, and other superior officers for the government of the city are elected, and they alone have the privilege of giving their votes for members of parliament; from which the rest of the citizens are excluded.

LIVES, or insurance of Lives. See INSURANCE, and LIFE.

LIXIVIUM. See PHARMACY.

LIZARD. See LACERTA.

LOAD, or LODE, in mining, a word used especially in the tin-mines, for any regular vein or course, whether metallic or not; but most commonly load means a metallic vein. It is to be observed, that mines in general are veins within the earth, whose sides receding from or approaching to each other, make them of unequal breadths in different places, sometimes forming large spaces, which are called holes; these holes are filled like the rest with substances, which, whether metallic, or of any other nature, are called loads. When the substances forming these loads are reducible to metal, the loads are by the English miners said to be alive, otherwise they are termed dead loads.

The load is frequently intercepted by the crossing of a vein of earth or stone, or some other metalline substance; in which case it generally happens, that one part of the load is moved to a considerable distance on one side. This load is by the miners termed a flooking, and the part of the load which is moved, is by them said to be heaved. This fracture or heave of a load, according to Mr. Price, is produced by a subsidence of the strata from their primary positions, which he supposes to have been horizontal or parallel to the surface of the earth, and therefore should more properly be called a depression than a heave. This heaving of the load would be an inexpressible loss to the miner, did not experience teach him that as the loads always run on the sides of the hills, so the part heaved is always moved toward the descent of the hill; so that the miner, working toward the ascent of the hill, and meeting a flooking, considers himself as working in the heaved part; wherefore, cutting through the flooking, he works upon its back up the ascent of the hill, till he recovers the load, and vice versa.

LOAMS. See HUSBANDRY.

LOANS, in political economy, sums of money, generally of large amount, borrowed from individuals or public bodies, for the service of the state. They are either compulsory, in which case they may be more properly termed requisitions; or voluntary, which is the only mode that can be frequently resorted to with advantage. Loans are sometimes furnished by public companies as a consideration for peculiar privileges secured to them; but are much more commonly advanced by individuals on a certain interest being allowed for the use of the money, either for a term of years, or until the principal shall be repaid.

The practice of borrowing money, for defraying part of the extraordinary expences in time of war, had been adopted in other countries long before it was introduced into Great Britain; but it has been carried to a far greater extent here than by any other state: and the facility with which the government has been enabled to raise the largest sums, has arisen entirely from the strict punctuality with which it has constantly made good all pecuniary engagements. The chancellor of the exchequer is the officer who usually conducts negotiations of this kind on the part of the government, and the agreement is afterward confirmed by parliament; the governor and company of the bank of England, have of late years been usually appointed receivers of the contributions, for which they have an allowance, at a certain rate per million; and the sums received by them are paid into the exchequer in the name of the chief cashier of the bank. The money appropriated to pay the interest or annuities, is issued at the receipt of the exchequer to the chief cashier of the bank upon account, and he is enjoined to pay the annuities, and render his account in due course. The bank detain their allowance for receiving the contributions out of the sum received, and likewise what they have allowed as discount to those subscribers who advanced their money before the times fixed for the several instalments.

When the parliament has voted the supplies, and the extent of the loan found necessary is determined, a communication is usually made to the bank or stock exchange stating the particular stock on which the loan is to be made, and fixing a day for those who intend to bid for it to wait on the minister with their proposals; in the mean time each person forms his list of friends who are to take different proportions with him in case he succeeds. When the day comes, each party offers as low as he thinks he can venture with a fair prospect of profit, and the lowest offer is generally accepted. The only step to be taken by those who are not of the number just mentioned, and who may wish to take a share in the transaction, is to apply to one of the subscribers for a part of his subscription, which at first may sometimes be had without any premium, or for a very small one, for it cannot be presumed that any small number of men, who have subscribed for the whole sum to be raised, intend, or can keep it, but that they propose to include in their subscriptions a great number of their connections and acquaintance. Sometimes the subscription lies open to the public at the bank, as in the instance of the loan of eighteen millions for the service of the year 1797, and then every person is at liberty to subscribe what he thinks proper; and if upon casting up the whole, there is a surplus subscribed, which has generally been the case, the sum each person has subscribed, is reduced in an equal proportion, so as to make in the whole the sum fixed by parliament.

As soon as conveniently may be, after the subscription is closed, receipts are made out, and delivered to the subscribers, for the several sums by them subscribed; and for the conveniency of sale, every subscriber of a considerable sum has sundry receipts for different proportions of his whole sum, by which means he can readily part with what sum he thinks proper; and a form of assignment is drawn upon the back of the receipt, which being signed and witnessed, transfers the property to any purchaser. The deposit is generally ten per cent. and is made at or about the time of subscribing; the second payment is about a month after, and so on till the whole is paid in, each instalment being usually either ten or fifteen per cent. Those subscribers who choose to pay the whole sum before the appointed days of payment, are allowed discount at an agreed rate per cent. on the sum paid in advance, from the time of such payment to the period when the whole is required to be paid in by instalments. Those who do not complete the payment of the sum they have subscribed for, forfeit the part they have paid; and this is the case according to the acts of parliament, if the money is not paid by the days appointed; but payments are sometimes received after the appointed days on paying certain fees to the clerk.

Loans are usually raised upon either redeemable or irredeemable annuities. The former are those which according to the conditions of the acts by which they are created, government may redeem without the consent of the proprietors, by discharging the debt at par; the latter are such as being granted for specific terms, cannot be redeemed without the consent of the proprietors. The various debts that have been incurred at different periods by loans on either of these species of annuities, constitute the funded debt of the nation; that is, the debt which has been secured upon certain funds, created by parliament, and appropriated to the payment of the annual interest on the sums borrowed. The constant hope of being able at a future period to redeem the debts contracted, has induced the government generally to prefer raising money on annuities redeemable at par; and the disadvantage which might arise to the stockholder from being paid off at par, if his principal bore a high rate of interest, has always made those who advance money on loans prefer a large capital bearing a low rate per cent. though it may actually produce a somewhat less annual interest than would have been given on a capital equal to the sum advanced: the great speculations which are carried on in the public funds are also a strong inducement to prefer advancing money on these conditions, which have contributed so much to increase the nominal magnitude of the national debt.

The terms of all the public loans which have been raised from the commencement of the funding system, have been collected by Mr J. J. Grellier, who observes, that "the economy or extravagance of every transaction of this kind depends on its correspondence or disagreement with the price of the public funds, and the current rate of interest at which money could be obtained on good security at the time the bargain was concluded; and consequently, a loan on which the highest interest is paid, may have been obtained on the best terms that could possibly be made at the time it was negotiated." The interest paid, however, forms the real burthen of each loan to the country, and is the circumstance to be chiefly attended to in all comparisons of the advantage or disadvantage of the terms on which the public debts have been contracted at different periods.

From the difference in the terms of the loan, with respect to the capital created, the rate of interest it bears, and the different periods of the terminable annuities which have been granted with most of the loans, it is evident, that in order to form a proper comparison of the rate of interest paid for the money borrowed at different periods, the various conditions must be brought into some degree of uniformity; and the most obvious mode of doing this is, by converting that part of the interest which consists of terminable annuities into equivalent perpetual annuities; that is, into the additional interest, which must have been paid in lieu of such terminable annuities.

The rate of interest at which such conversion is made affects the result in some instances very materially; thus, the perpetual annuity, which is equal to an annuity of 10*l.* for 21 years, is, at 3 per cent. 4*l.* 12*s.* 5*d.* but at 5 per cent. 6*l.* 8*s.* 2*d.*; and the perpetual annuity equal to an annuity of 10*l.* for 60 years, which at 3 per cent. is 8*l.* 6*s.* is at 5 per cent. 9*l.* 9*s.* 3*d.* from which it is evident, that, if the terminable annuities, granted at different periods, are all valued at the same rate of interest, the comparison will by no means be just; for if a high rate is adopted, the loans which have been obtained at the lowest interest will be set in an unfavourable view; and if, on the contrary, they are all valued at a low rate, the charge of those loans, for which the highest interest is paid, will appear less than it really is. Nor is a medium or average rate more proper for exhibiting the real difference in the terms on which the several loans have been obtained. The least objectionable mode appears to be to convert the terminable annuities into perpetual annuities, according to the current rate of interest at the time when the annuities were granted, as it is upon the rate of interest that the proportionate value of an annuity for a certain term to the perpetuity depends; and in forming the following statements, the conversion has been made at the interest produced by money invested in the three per cents. according to the price of this stock at the times when the terms of the respective loans were settled: for, though by this means, the rate is, in each case, rather lower than it would have been had the interest produced by 4 or 5 per cent. stock been adopted, it is most probable, from the nature of the principal loans, that the stock which must have been given in lieu of a long annuity, would chiefly have been three per cents.; and, therefore, the interest equivalent to the long annuity should be found according to the interest produced by this stock. It may also be proper to remark, that, as the terminable annuities have mostly been granted for a long term, and form but a small part of the whole interest, particularly on the loans of the last war, the difference of a quarter or even half per cent. in the rate at which they are valued has in general but little effect on the whole rate per cent. of the loan. Thus, if the long annuity of the loan of 14,500,000*l.*, in 1797, is valued at 6 per cent. (being the interest produced by 3 per cents. at that time) it makes the whole rate per cent. 6*l.* 6*s.* 10*d.*; but, if the long annuity is valued at $5\frac{3}{4}$ per cent. it will be 6*l.* 6*s.* $9\frac{3}{4}$*d.*; at $5\frac{1}{2}$ per cent. 6*l.* 6*s.* $9\frac{1}{4}$*d.*; and, at 5 per cent. 6*l.* 6*s.* $8\frac{1}{2}$*d.* On the loan of 1798, the difference would be still less.

Till the last war, the lottery generally formed part of the terms of the loan; every subscriber of a certain sum towards the latter being entitled to a certain number of tickets, at 10*l.* each, the price at which the lottery-scheme is usually formed. As the whole profits of the lotteries were thus given up to the subscribers, a part of the money advanced must be considered as equivalent to the sum which government would otherwise have received for the lottery, and is therefore to be deducted from the whole sum advanced on the loan. This profit is variable, but has generally been taken at the average of 2*l.* 10*s.* per ticket; making, on a lottery of 50,000 tickets, 125,000*l.* to be deducted from the sum advanced, in estimating the rate of interest paid thereon.

There are some other circumstances which affect the interest paid: such as the discount allowed for prompt payment, the different periods of the instalments, and the times from which the annuities commence; but as these drawbacks do not in general amount to any considerable sum, in comparison with the whole amount of the loan, they do not materially augment the rate of interest; and as they more or less affect all the loans, they are of still less importance in a comparative view. In the following statement, however, a deduction is made on the loans of 18,000,000*l.* in 1796 and 1797, on account of the advantage allowed with respect to the time from which the annuities commenced, being greater than usual.

It is unnecessary to enter into a particular investigation of the interest paid for the money borrowed in the infancy of the funding system, as the first loans differed materially from those of subsequent periods, in being raised wholly on terminable annuities, and in having a particular fund assigned for each loan, by the supposed adequateness or insufficiency of which the interest required by the lenders was frequently influenced, as well as by other causes, which have since ceased to exist.

During the reign of queen Anne, loans were chiefly raised on annuities for 99 years, till 1711, when, by the establishment of the South Sea company, a variety of debts were consolidated and made a permanent capital, bearing 6 per cent. interest. About this period lotteries were also frequently adopted for raising money for the public service, under which form a considerable premium was given, in addition to a high rate of interest. This mode of raising money was followed in 1712, 1713, and 1714. In the latter year, though the interest paid was equal to only 5*l.* 7*s.* 2*d.* per cent. on the sum borrowed, the premium allowed was upwards of 34*l.* per cent.; but as peace was restored, and the legal rate of interest had been reduced to 5 per cent. it seems that a larger premium was allowed, for the sake of appearing to borrow at a moderate rate of interest.

In the reign of George I. the interest on a considerable part of the public debts was reduced to 5 per cent. and the few loans that were raised were comparatively of small amount: that of the year 1720 was obtained at little more than 4 per cent. interest.

About 1730 the current rate of interest was 3½ per cent.; and in 1736, government was enabled to borrow at 3 per cent. per annum. The extraordinary sums necessary for defraying the expences of the war which began in 1739, were at first obtained from the sinking fund and the salt duties; a payment from the bank, in 1742, rendered only a small loan necessary in that year, which was obtained at little more than 3 per cent. interest. In the succeeding years the following sums were raised by loans:

	Sum borrowed.	Interest.
1743	£1,800,000	£3 8 4
1744	1,800,000	3 6 10
1745	2,000,000	4 0 7
1746	2,500,000	5 5 1
1747	4,000,000	4 8 0
1748	6,300,000	4 8 0
Loans of the seven years war.		
1756	2,000,000	3 12 0
1757	3,000,000	3 14 3
1758	5,000,000	3 6 5
1759	6,600,000	3 10 9
1760	8,000,000	3 13 7
1761	12,000,000	4 1 11
1762	12,000,000	4 10 9
1763	3,500,000	4 4 2
Loans of the American war.		
1776	2,000,000	3 9 8
1777	5,000,000	4 5 2
1778	6,000,000	4 18 7
1779	7,000,000	5 18 10
1780	12,000,000	5 16 8
1781	12,000,000	5 11 1
1782	13,500,000	5 18 1
1783	12,000,000	4 13 9
1784	6,000,000	5 6 11
Loans of the war with the French republic.		
1793	4,500,000	4 3 4
1794	11,000,000	4 10 7
1795	18,000,000	4 15 8
1796	18,000,000	4 14 9
1796	7,500,000	4 12 2
1797	18,000,000	5 14 1
1797	14,500,000	6 6 10
1798	17,000,000	6 4 9
1799	3,000,000	5 12 5
1799	15,500,000	5 5 0
1800	20,500,000	4 14 2
1801	28,000,000	5 5 5
Loans of the war with the French empire.		
1803	12,000,000	5 2 0
1804	14,500,000	5 9 2
1805	22,500,000	5 3 2
1806	20,000,000	4 19 7

LOASA, a genus of the polyandria monogynia class and order. The cal. is five-leaved; cor. five-petalled; nect. five-leaved; caps. turbinate, one-celled, three-valved, many-seeded. There is one species, an annual of South America.

LOBE. See Anatomy.

LOBELIA, cardinal-flower, a genus of the monogamia order, in the syngenesia class of plants, and in the natural method ranking under the 29th order, campanaceæ. The calyx is quinquefid; the corolla monopetalous and irregular; the capsule inferior, bilocular or trilocular. There are 42 species, but only four of them are cultivated in our gardens, two of which are hardy herbaceous plants for the open ground, and two shrubby plants for the stove. They are all fibrous-rooted perennials, rising with erect stalks from two to five or six feet high, ornamented with oblong, oval, spear-shaped, simple leaves, and spikes of beautiful monopetalous, somewhat ringent, five-parted flowers, of scarlet, blue, and violet colours. They are easily propagated by seeds, offsets, and cuttings of their stalks. The tender kinds require the common treatment of other exotics. They are natives of America, from which their seeds must be procured.

The root of the species called the syphilitica (see Plate Nat. Hist. fig. 252.) is an article of the materia medica. This species grows in most places in Virginia, and bears our winters. It is perennial, has an erect stalk three or four feet high, blue flowers, a milky juice, and a rank smell. The root consists of white fibres about two inches long, resembles tobacco in taste, which remains on the tongue, and is apt to excite vomiting. It is used by the North American Indians as a specific in the venereal disease. The benefit, however, to be derived from this article has not, as far as we know, been confirmed either in Britain or by the practitioners in Virginia.

LOCAL, in law, something fixed to the freehold, or tied to a certain place: thus, real actions are local, since they must be brought in the country where they lie, and local customs are those peculiar to certain countries and places.

Local problem, among mathematicians, such a one as is capable of an infinite number of different solutions, by reason that the point which is to resolve the problem may be indifferently taken within a certain extent, as suppose any where within such a line, within such a plane figure, &c. which is called a geometric locus, and the problem is said to be a local or indetermined one.

A local problem may be either simple, when the point sought is in a right light; plane, when the point sought is in the circumference of a circle; solid, when the point required is in the circumference of a conic section; or lastly, sursolid, when the point is in the perimeter of a line of the second gender, or of a higher kind, as geometers call it.

LOCHIA. See Midwifery.

LOCK, a well-known instrument, and reckoned the masterpiece in smithery; a great deal of art and delicacy being required in contriving and varying the wards, springs, bolts, &c. and adjusting them to the places where they are to be used, and to the various occasions of using them. From the various structure of locks, accommodated to their different intentions, they acquire various names. Those placed on outer doors are called stock-locks; those on chamber-doors, spring-locks; those on trunks, trunk-locks, padlocks, &c. Of these the spring-lock is the most considerable, both for its frequency and the curiosity of its structure.

A treatise upon this subject has been published by Mr. Joseph Bramah, who begins with observing, that the principle on which all locks depend, is the application of a lever to an interior bolt, by means of a communication from without; so that, by means of the latter, the lever acts upon the bolt, and moves it in such a manner as to secure the lid or door from being opened by any pull or push from without. The security of locks in general, therefore, depends on the number of impediments we can interpose betwixt the lever (the key) and the bolt which secures the door; and these impediments are well known by the name of wards, the number and intricacy of which alone are supposed to distinguish a good lock from a bad one. If these wards, however, do not in an effectual manner preclude the access of all other instruments besides the proper key, it is still possible for a mechanic of equal skill with the lock-maker to open it without the key, and thus to elude the labour of the other. "As nothing (says Mr. Bramah) can be more opposite in principle to fixed wards than a lock which derives its properties from the motion of all its parts, I determined that the construction of such a lock should be the subject of my experiment." In the prosecution of this experiment, he had the satisfaction to find that the least perfect of all his models fully ascertained the truth and certainty of his principle. The exclusion of wards made it necessary to cut off all communication between the key and the bolt; as the same passage which (in a lock simply constructed) would admit the key, might give admission likewise to other instruments. The office, therefore, which in other locks is performed by the extreme point of the key, is here assigned to a lever, which cannot approach the bolt till every part of the lock has undergone a change of position. The necessity of this change to the purposes of the lock, and the absolute impossibility of effecting it otherwise than with the proper key, are the points to be ascertained.

Plate Lock and Loom, fig. 4, represents a mortice lock, made under the patent which Mr. Stansbury took out in 1805, for various improvements in locks, in which A is the spring-latch, as in common; the end B of this is bent, and has a frame D screwed to it, carrying a roller E; against this roller a wedge F called a pusher, shewn separately in fig. 5, acts; the spindle G on which this pusher is fixed, slides through holes in the side-plate of the lock, so as to have no shake, and on each end is fastened a handle; by this arrangement it is plain that when the handle of the wedge is pushed from without the door, its wedge E will act against the roller E, fig. 4, draw back the bolt A, and release the door; a continuation of the same motion opens it. The operations from within the room are the same, except that the handle of the pusher must be pulled instead of pushed; but as it is on the other end of the spindle, the operation on the wedge and bolt is the same. For the convenience of persons not acquainted with the new method, the bolt may be drawn back by turning the handle, as in the common lock. H is a piece of metal, figs. 4 and 5, which has a round collar *a* above, and another *b* beneath, which work in holes in the two side-plates of the lock, so as to turn easily round; this piece has a hole through it, large enough to admit the pusher to move up and down; and an opening in one side thereof admits the wedge F; so that when the spindle is turned round, one of the two arms *d e* of this piece, acts against the arm B of the bolt A, fig. 4, and draws back the bolt when the handle is turned, as in the common way. In order to reduce the friction against the bolt, in shutting the door, a small roller *a*, fig. 1, is applied to it. In lieu of the slip-bolt of common locks, Mr. Stansbury uses a piece I, which has a spindle going through the plate of the lock, and projecting from the door with a handle on it, by which its arm *f* can be moved up and down, when the door is to be bolted; this handle is turned so that the knob *g* on the arm *f* may fall in the notch cut in the bolt to receive it; this prevents the bolt being moved back by the pusher, till the arm *f* is first removed. There is a spring at the back of this arm, which pressing against the plate of the lock, by its friction keeps it from falling by accident. K is the main bolt of the lock; it is kept steady by a rectangular opening, through which a screw passes. The bolt is moved by a circular iron plate, moving round a pin *h*, which is riveted into a circular bridge N, screwed to the plate shewn separately in fig. 3; this bridge has a circular opening *i* in it, through which a pin *e*, riveted to the plate L, moves; this pin takes into a notch in the bolt, so as to move it backwards and forwards, when the plate is turned round its centre. The locking part is performed thus: the wheel L has a certain number of holes drilled in it, as at *m*; the bridge has the same number of similar holes in it, and in the same position; each hole in the bridge has a small pin in it, which is pushed in by a slight spring *n n n*, fig. 3; when the holes in the plate coincide with the holes in the bridge, the springs *n n n* push up the pins through the plate, and lock them both together. The key, fig. 2, has the same number of pins projecting from its lower end, as the pin-holes in the bridge, and in the same position; the length of the pins is the same as the thickness of the plate L, fig. 4. When it is to be unlocked, the key is introduced, and as it is turned round, it is pushed gently forward against the plate; when the pins and key come opposite the pin-holes and pins, the force applied overcomes the resistance of the springs *n n n*, the pins are pushed out, and the key gets hold of the plate L, when being turned round, it draws the bolt back by the pin *b*, fig. 3.

LOCUS GEOMETRICUS, denotes a line by which a local or indeterminate problem is solved.

A locus is a line, any point of which may equally solve an indeterminate problem. Thus, if a right line suffice for the construction of the equation, it is called *locus ad rectum*; if a circle, *locus ad circulum*; if a parabola, *locus ad parabolam*; if an ellipsis, *locus ad ellipsin*; and so of the rest of the conic sections. The loci of such equations as are right lines, or circles, the ancients called plane loci; and of those that are parabolas, hyperbolas, &c. solid loci. But Wolfius, and others among the moderns, divide the loci more commodiously into orders, according to the number of dimensions to which the indeterminate quantities rise. Thus, it will be a locus of the first order, if the equation is $x = \frac{ay}{c}$; a locus of the second or quadratic order, if $y^2 = ax$, or $y^2 = a^2 - x^2$; a locus of the third or cubic order, if $y^3 = a^2x$, or $y^3 = ax^2 - x^3$, &c.

All equations whose loci are of the first order, may be reduced to some one of the four following formulas: 1. $y = \frac{bx}{a}$. 2. $y = \frac{bx}{a} + c$. 3. $y = \frac{bx}{a} - c$. 4. $y = c - \frac{bx}{a}$: where the unknown quantity y, is supposed always to be freed from fractions, and the fraction that multiplies the other unknown quantity x, to be reduced to this expression $\frac{b}{a}$, and all the known terms to c.

All loci of the second degree are conic sections, viz. either the parabola, the circle, ellipsis, or hyperbola: if an equation, therefore, is given, whose locus is of the second degree, and it is required to draw the conic section which is the locus thereof, first draw a parabola, ellipsis, or hyperbola, so as that the equations expressing the natures thereof may be as compound as possible, in order to get general equations or formulas, by examining the peculiar properties whereof we may know which of these formulas the given equation ought to have regard to; that is, which of the conic sections will be the locus of the proposed equation. This known, compare all the terms of the proposed equation with the terms of the general formula of that conic section, which you have found will be the locus of the given equation; by which means you will find how to draw the section which is the locus of the equation given.

If an equation, whose locus is a conic section, is given, and the particular section whereof it is the locus is required; all the terms of the given equation being brought over to one side, so that the other is equal to nothing, there will be two cases.

Case I. When the rectangle xy is not in the given equation. 1. If either yy or xx is in the same equation, the locus will be a parabola. 2. If both xx and yy are in the equation with the same signs, the locus will be an ellipsis or a circle. 3. If xx and yy have different signs, the locus will be an hyperbola, or the opposite sections regarding their diameters.

Case II. When the rectangle xy is in the given equation. 1. If neither of the squares xx or yy, or only one of them, is in the same, the locus of it will be an hyperbola between the asymptotes. 2. If yy and xx is therein, having different signs, the locus will be an hyperbola regarding its diameters. 3. If both the squares xx and yy are in the equation, having the same signs, you must free the square yy from fractions; and then the locus will be an hyperbola, when the square of $\frac{1}{2}$ the fraction multiplying xy, is equal to the fraction multiplying xx; an ellipsis, or circle, when the same is less; and an hyperbola, or the opposite sections, regarding their diameters, when greater.

LOCUST. See GRYLLUS.

LODGMENT, in military affairs, is a work raised with earth, gabions, fascines, woolpacks, or mantelets, to cover the besiegers from the enemy's fire, and to prevent their losing a place which they have gained, and are resolved, if possible, to keep. For this purpose, when a lodgment is to be made on the glacis, covered way, or in the breach, there must be great provision made of fascines, sand-bags, &c. in the trenches; and during the action, the pioneers with fascines, sand-bags, &c. should be making the lodgment, in order to form a covering in as advantageous a manner as possible from the opposite bastion, or the place most to be feared.

LOEFLINGIA, a genus of the class and order triandria monogynia. The calyx is five-leaved; corolla five-petalled; capsule one-celled, three-valved. There is one species, an annual of Spain.

LOESELIA, a genus of the didynamia angiospermia class of plants, the flower of which is monopetalous and quinquefid at the limb; the fruit is a trilocular capsule, with several angulated seeds in each cell. There is one species, a herb of South America.

LOG, in naval affairs, is a flat piece of wood, shaped somewhat like a flounder, with a piece of lead fastened to its bottom, which makes it stand or swim upright in the water. To this log is fastened a long line, called the log-line; and this is commonly divided into certain spaces 50 feet in length by knots, which are pieces of knotted twine inreeved between the strands of the line; which shew, by means of a half-minute glass, how many of these spaces or knots are run out in half a minute. They commonly begin to be counted at the distance of about 10 fathoms or 60 feet from the log; so that the log, when it is hoven overboard, may be out of the eddy of the ship's wake before they begin to count: and for the ready discovery of this point of commencement, there is commonly fastened at it a red rag.

The log being thus prepared, and hoven overboard from the poop, and the line veered out by the help of a reel, as fast as the ship sails from it, will shew how far the ship has run in a given time, and consequently her rate of sailing.

Hence it is evident, that as the distance of the knots bears the same proportion to a mile as half a minute does to an hour, whatever number of knots the ship runs in half a minute, the same number of miles she will run in an hour, supposing her to run with the same degree of velocity during that time; and therefore, in order to know her rate of sailing, it is the general way to heave the log every hour; but if the force or direction of the wind varies, and does not continue the same during the whole hour, or if there has been more sail set, or any sail handed in, by which the ship has sailed faster or slower than she did at the time of heaving the log, there must then be an allowance made for it accordingly.

LOG-BOARD, a table generally divided into five columns, in the first of which is entered the hour of the day; in the second the course steered; in the third, the number of knots run off the reel each time of heaving the log; in the fourth, from what point the wind blows; and in the fifth, observations on the weather, variation of the compass, &c.

LOG-BOOK, a book ruled in columns like the log-board, into which the account on the log-board is transcribed every day at noon; whence, after it is corrected, &c. it is entered into the journal. See NAVIGATION.

LOG-WOOD, in commerce. See HÆMATOXYLUM.

Logwood is used by dyers for dying blacks and blues.

LOGARITHMIC, in general, something belonging to logarithms. See LOGARITHMS.

LOGARITHMIC CURVE. If on the line AN (Plate Miscel., fig. 155.) both ways indefinitely extended, be taken, AC, CE, EG, GI, IL, on the right hand, and A*g*, *g*P, &c. on the left, all equal to one another; and if at the points P, *g*, A, C, E, G, I, L, be erected to the right line AN, the perpendiculars PS, *gd*, AB, CD, EF, GH, IK, LM, which let be continually proportional, and represent numbers, viz. AB, 1; CD, 10; EF, 100, &c. then shall we have two progressions of lines, arithmetical and geometrical: for the lines AC, AE, AG, &c. are in arithmetical progression, or as 1, 2, 3, 4, 5, &c. and so represent the logarithms to which the geometrical lines AB, CD, EF, &c. do correspond. For since AG is triple of the right line AC, the number GH shall be in the third place from unity, if CD is in the first; so likewise shall LM be in the fifth place, since AL = 5 AC. If the extremities of the proportionals S, *d*, B, D, F, &c. are joined by right lines, the figure SBML will become a polygon, consisting of more or less sides, according as there are more or less terms in the progression.

If the parts AC, CE, EG, &c. are bisected in the points *c*, *e*, *g*, *i*, *l*, and there are again raised the perpendiculars *cd*, *ef*, *gh*, *ik*, *lm*, which are mean proportionals between AB, CD; CD, EF, &c. then there will arise a new series of proportionals, whose terms beginning from that which immediately follows unity, are double of those in the first series, and the difference of the terms is become less, and approaches nearer to a ratio of equality, than before. Likewise, in this new series, the right lines AL, A*c*, express the distances of the terms LM, *cd*, from unity, viz. since AL is ten times greater than A*c*, LM shall be the tenth term of the series from unity; and because A*e* is three times greater than A*c*, *ef* will be the third term of the series if *cd* is the first, and there shall be two mean proportionals between AB and *ef*; and between AB and LM there will be nine mean proportionals. And if the extremities of the lines B*d*, D*f*, F*h*, &c. are joined by right lines, there will be a new polygon made, consisting of more but shorter sides than the last.

If, in this manner, mean proportionals are continually placed between every two terms, the number of terms at last will be made so great, as also the number of the sides of the polygon, as to be greater than any given number, or to be infinite; and every side of the polygon so lessened, as to become less than any given right line; and consequently the polygon will be changed into a curve-lined figure: for any curve-lined figure may be conceived as a polygon whose sides are infinitely small and infinite in number. A curve described after this manner, is called logarithmical.

It is manifest, from this description of the logarithmic curve, that all numbers at equal distances are continually proportional. It is also plain, that if there are four numbers, A B, C D, I K, L M, such that the distance between the first and second, is equal to the distance between the third and fourth, let the distance from the second to the third be what it will, these numbers will be proportional. For because the distances A C, I L, are equal, A B shall be to the increment D *s*, as I K is to the increment M T. Wherefore, by composition, A B : D C :: I K : M L. And contrariwise, if four numbers are proportional, the distance between the first and second shall be equal to the distance between the third and fourth.

The distance between any two numbers, is called the logarithm of the ratio of those numbers; and, indeed, does not measure the ratio itself, but the number of terms in a given series of geometrical proportionals, proceeding from one number to another, and defines the number of equal ratios by the composition whereof the ratios of numbers are known.

LOGARITHMS are numbers so contrived and adapted to other numbers, that the sums and differences of the former shall correspond to, and shew, the products and quotients of the latter.

Or, more generally, logarithms are the numerical exponents of ratios; or a series of numbers in arithmetical progression, answering to another series of numbers in geometrical progression. Thus,

0, 1, 2, 3, 4, 5, Indices, or logarithms.
1, 2, 4, 8, 16, 32, Geometric progression.

Or,

0, 1, 2, 3, 4, 5, Indices, or logarithms.
1, 3, 9, 27, 81, 243, Geometric progression.

Or,

0, 1, 2, 3, 4, 5, Ind. or log.
1, 10, 100, 1000, 10000, 100000, Geo. prog.

Where it is evident that the same indices serve equally for any geometric series; and consequently there may be an endless variety of systems of logarithms to the same common numbers, by only changing the second term, 2, 3, or 10, &c. of the geometrical series.

It is also apparent, from the nature of these series, that if any two indices be added together, their sum will be the index of that number which is equal to the product of the two terms, in the geometric progression, to which those indices belong.

Thus, the indices 2 and 3, being added together, are = 5; and the numbers 4 and 8, or the terms corresponding with those indices, being multiplied together, are = 32, which is the number answering to the index 5.

And, in like manner, if any one index be subtracted from another, the difference will be the index of that number, which is equal to the quotient of the two terms to which those indices belong.

Thus the index 6, minus the index 4, is = 2; and the terms corresponding to those indices are 64 and 16, whose quotient is = 4; which is the number answering to the index 2.

For the same reason, if the logarithm of any number are multiplied by the index of its power, the product will be equal to the logarithm of that power.

Thus, the index or logarithm of 4, in the above series, is 2; and if this number is multiplied by 3, the product will be = 6; which is the logarithm of 64, or the third power of 4.

And, if the logarithm of any number is divided by the index of its root, the quotient will be equal to the logarithm of that root.

Thus, the index or logarithm of 64 is 6; and if this number is divided by 2, the quotient will be = 3; which is the logarithm of 8, or the square root of 64.

The logarithms most convenient for practice are such as are adapted to a geometric series increasing in a tenfold proportion, as in the last of the above forms; and are those which are to be found, at present, in most of the common tables upon this subject.

The distinguishing mark of this system of logarithms is, that the index, or logarithm, of 1 is 0; that of 10, 1; that of 100, 2; that of 1000 3, &c. And in decimals the logarithm of .1 is − 1; that of .01, − 2; that of .001, − 3, &c.

From whence it follows that the logarithm of any number between 1 and 10 must be 0 and some fractional parts, and that of a number between 10 and 100 will be 1 and some fractional parts; and so on for any other number whatever.

And since the integral part of a logarithm is always thus readily found, it is usually called the index, or characteristic; and is commonly omitted in the tables; being left to be supplied by the operator himself, as occasion requires.

Of the Making of Logarithms. Whatever arithmetical progression we apply to a geometrical one, the terms of it are logarithms only to that series to which we apply them, and answer the end proposed only for those particular numbers; so that if we had logarithms adapted only to particular geometrical series, they would be but of little use. The great end and design of these numbers is the ease and expedition which they afford in long calculations, by saving the laborious work of multiplication, division, and the extraction of roots: but this end would never be completely answered, unless logarithms could be adapted to the whole system of numbers, 1, 2, 3, 4, &c. And as here lie the chief excellence and merit of the contrivance, so also the difficulty. For the natural system of numbers, 1, 2, 3, 4, &c. being an arithmetical, and not a geometrical series, seems rather fit to be made logarithms of, than to have logarithms applied to it. But this difficulty may be easily removed, by considering,

That though the whole system of natural numbers, 1, 2, 3, 4, &c. is not in geometrical progression, and cannot, by any means, be made to agree with such a series, yet it may be brought so near it, as to be within any assignable degree of approximation; which may be conceived, in general, thus: suppose a fraction indefinitely small to be represented by x, and a geometrical series arising from 1, in the ratio of 1 to $1 + x$, to be 1, $(1 + x)^1$, $(1 + x)^2$, $(1 + x)^3$, $(1 + x)^4$, &c. Then some of these terms must come indefinitely near to all the natural numbers, 1, 2, 3, 4, &c.; because, amongst numbers which arise by extremely small increments, some of them must exceed, or fall short of, any determinate number, by an indefinitely little excess or defect.

If, therefore, in the places of the terms of this series, which approach indefinitely near to any of the natural numbers, we suppose these natural numbers themselves to be substituted, then will this series be in geometrical progression, to an exactness which may be called indefinite; because the approximation of its terms to the natural numbers can never end but goes on *in infinitum*.

And since this imagined geometric series comprehends, indefinitely near, the whole system of natural numbers, 1, 2, 3, 4, &c. so the indices of its terms comprehend a whole system of logarithms, which are adapted to this system of numbers, and may be extended to any length we please. For though the natural system of numbers make not, by themselves, a complete geometrical series, yet they are conceived as a part of such a series, and their logarithms are the indices of their distances from unity in that series; or, more generally, they are the corresponding terms of an arithmetical series applied to that geometrical one.

But, again, it must be observed, that an indefinitely small fraction cannot be assigned: and, therefore, in the actual construction of logarithms, we must be content with a determinate degree of approximation. Whence, according as we take x, in the series 1, $(1 + x)^1$, $(1 + x)^2$, $(1 + x)^3$, $(1 + x)^4$, &c. the approximation of its terms to the natural numbers will be in different degrees of exactness: for the less x is, the nearer will be the approximation; but then the more are the number of involutions of $1 + x$, necessary to come within any determinate degree of nearness to the natural number assigned.

Thus then we may conceive the possibility of making logarithms to all the natural numbers, 1, 2, 3, 4, &c. to any determinate degree of exactness; viz. by assigning a very small fraction for x, and actually raising a series, in the ratio of 1 to $1 + x$, and taking for the natural numbers such terms of that series as are nearest to them, and their indices for the logarithms. But then, to construct logarithms in this manner, to such an extent of numbers, and degree of exactness, as would be necessary to make them of any considerable use, is next to impossible, because of the almost infinite labour and time it would require. This, however, is an introduction for understanding the method of the noble inventor, who undoubtedly first took the hint of making logarithms from the consideration of the indices of a geometrical series; and by means of the principles and known properties of these progressions he first formed his tables, and adapted them to the practical purposes intended.

To find the logarithm of any of the natural numbers, 1, 2, 3, 4, *&c. according to the method of* Napier.—1. Take the geometrical series, 1, 10, 100, 1000, 10,000, &c. and apply to it the arithmetical series 1, 2, 3, 4, &c. as logarithms. 2. Find a geometric mean between 1 and 10, 10 and 100, or any other two adjacent terms of the series betwixt which the number proposed lies. 3. Between the mean, thus found, and the nearest extreme, find another geometrical mean, in the same manner; and so on, till you are arrived within the proposed limit of the number whose logarithm is sought. 4. Find as many arithmetical means, in the same order as you found the geometrical ones, and the last of these will be the logarithm answering to the number required.

Examples. Let it be required to find the logarithm of 9.

Here the numbers between which 9 lies are 1 and 10.

First, then, the log. of 10 is 1, and the log. of 1 is 0; therefore $\frac{1+0}{2} = .5$ is the arithmetical mean, and $\sqrt{(1 \times 10)} = \sqrt{10} = 3.1622777 =$ geometric mean: whence the logarithm of 3.1622777 is .5.

Secondly, the log. of 10 is 1, and the log. of 3.1622777 is .5; therefore $\frac{1+.5}{2} = .75 =$ arithmetical mean, and $\sqrt{(10 \times 3.1622777)} = 5.6234132 =$ geometric mean: whence the log. of 5.6234132 is .75.

Thirdly, the log. of 10 is 1, and the log. of 5.6234132 is .75; therefore $\frac{1+.75}{2} = .875 =$ arithmetical mean, and $\sqrt{(10. \times 5.6234132)} = 7.4989421 =$ geometric mean: whence the log. of 7.4989421 is .875.

Fourthly, the log. of 10 is 1, and the log. of 7.4989421 is .875; therefore $\frac{1+.875}{2} = .9375 =$ arithmetical mean, and $\sqrt{(10 \times 7.4989421)} = 8.6596431 =$ geometric mean: whence the log. of 8.6596431 is .9375.

Fifthly, the log. of 10 is 1, and the log. of 8.6596431 is .9375; therefore $\frac{1+.9375}{2} = .96875 =$ arithmetical mean, and $\sqrt{(10 \times 8.6596431)} = 9.3057204 =$ geometric mean: whence the log. of 9.3057204 is .96875.

Sixthly, the log. of 8.6596431 is .9375, and the log. of 9.3057204 is .96875; therefore $\frac{.9375+.96875}{2} = .953125 =$ arith. mean, and $\sqrt{(8.6596431 \times 9.3057204)} = 8.9768713 =$ geometric mean: whence the log. of 8.9768713 is .953125.

And, proceeding in this manner, after 25 extractions, the logarithm of 8.9999998 will be found to be .9542425; which may be taken for the logarithm of 9, because it differs from it only by $\frac{1}{5000000}$, and is therefore sufficiently exact for all practical purposes.

And in the same manner the logarithms of almost all the prime numbers were found; a work so incredibly laborious, that the unremitted industry of several years was scarcely sufficient for its accomplishment.

To determine the hyperbolic logarithm (L) *of any given number* (N). The hyperbolic logarithm of any number is the index of that term of the logarithmic progression, which agrees with the proposed number multiplied by the excess of the common ratio above unity.

Let, therefore, $(1+x)^n$ be that term of the logarithmical progression, 1, $(1+x)^1$, $(1+x)^2$, $(1+x)^3$, $(1+x)^4$, &c. which is equal to the required number (N).

Then will $(1+x)^n = N$, and $1+x = N^{\frac{1}{n}}$; and if $1+y$ be put $= N$, and $m = \frac{1}{n}$, we shall have $1+x = N^{\frac{1}{n}} = (1+y)^m = 1 + my + m \times \frac{m-1}{2} y^2 + m \times \frac{m-1}{2} \times \frac{m-2}{3} y^3$, &c.

And, consequently, $x = my + m \times \frac{m-1}{2} y^2 + m \times \frac{m-2}{2} \times \frac{m-2}{3} y^3$, &c. where m being rejected in the factors $m-1$, $m-2$, $m-3$, &c. being indefinitely small in comparison of 1, 2, 3, &c. the equation will become $x = my - \frac{my^2}{2} + \frac{my^3}{3} - \frac{my^4}{4}$, &c.

Hence $\frac{x}{m}$ $(nx = L) = y - \frac{y^2}{2} + \frac{y^3}{3} - \frac{y^4}{4} + \frac{y^5}{5}$, &c. $=$ hyperbolic logarithm of N, as was required.

The hyperbolic logarithm (L) *of a number being given, to find the number* (N) *itself, which answers to it.* Let $(1+x)^n$ be that term of the logarithmic progression, 1, $(1+x)^1$, $(1+x)^2$, $(1+x)^3$, $(1+x)^4$, &c. which is equal to the required number N.

Then, because $(1+x)^n$ is universally $= 1 + nx + n \times \frac{n-1}{2} x^2 + n \times \frac{n-1}{2} \times \frac{n-2}{3} x^3$, &c. we shall have $1 + nx + n \times \frac{n-1}{2} x^2 + n \times \frac{n-1}{2} \times \frac{n-2}{3} x^3$, &c. $= N$.

But since n, from the nature of the logarithms, is here supposed indefinitely great, it is evident that the numbers connected to it by the sign — may all be rejected, as far as any assigned number of terms.

For as 1, 2, 3, &c. are indefinitely small in comparison to n, the rejecting of those numbers can very little affect the values to which they belong.

If, therefore, 1, 2, 3, &c. be thrown out of the factors $\frac{n-1}{2}$, $\frac{n-2}{3}$, $\frac{n-3}{4}$, &c. we shall have $1 + nx + \frac{n^2x^2}{2} + \frac{n^3x^3}{2.3} + \frac{n^4x^4}{2.3.4}$, &c. $= N$.

But nx $(= L)$ is the hyperbolic logarithm of $(1+x)^n$, or N, by what has been before specified; and therefore $1 + L + \frac{L^2}{2} + \frac{L^3}{2.3} + \frac{L^4}{2.3.4}$, &c. $= N =$ number required.

Of the Method of using a Table of Logarithms.—Having explained the method of making a table of the logarithms of numbers greater than unity, the next thing to be done is, to shew how the logarithms of fractional quantities may be found. And, in order to this, it may be observed, that as we have hitherto supposed a geometric series to increase from an unit on the right hand, so we may now suppose it to decrease from an unit towards the left; and the indices, in this case, being made negative, will still exhibit the logarithms of the terms to which they belong.

Thus Log.	-3	-2	-1	0	$+1$	$+2$	$+3$,	&c.
Num.	$\frac{1}{1000}$	$\frac{1}{100}$	$\frac{1}{10}$	1	10	100	1000,	&c.

Whence $+1$ is the logarithm of 10, and -1, the logarithm of $\frac{1}{10}$; $+2$ the logarithm of 100, and -2 the logarithm of $\frac{1}{100}$, &c.

And from hence it appears that all numbers, consisting of the same figures, whether they be integral, fractional, or mixed, will have the decimal parts of their logarithms the same.

Thus, the logarithm of 5874 being 3.7689339, the logarithm of $\frac{1}{10}$, $\frac{1}{100}$, $\frac{1}{1000}$, &c. part of it will be as follows:

Num.	Logarithms.
5874	3.7689339
587.4	2.7689339
58.74	1.7689339
5.874	0.7689339
.5874	— 1.7689339
.05874	— 2.7689339
.005874	— 3.7689339

From this it also appears, that the index, or characteristic, of any logarithm, is always one less than the number of figures which the natural number consists of: and this index is constantly to be placed on the left hand of the decimal part of the logarithm.

When there are integers in the given number, the index is always affirmative; but when there are no integers, the index is negative, and is to be marked by a line drawn before it, like a negative quantity in algebra.

Thus, a number having 1, 2, 3, 4, 5, &c. integer places, the index of its log. is 0, 1, 2, 3, 4, &c. And a fraction having a digit in the place of primes, seconds, thirds, fourths, &c. the index of its logarithm will be -1, -2, -3, -4, &c.

It may also be observed, that though the indices of fractional quantities are negative, yet the decimal parts of their logarithms are always affirmative; and all operations are to be performed by them in the same manner as by negative and affirmative quantities in algebra.

In taking out of a table the logarithm of any number not exceeding 10000, we have the decimal part by inspection; and if to this the proper characteristic be affixed, it will give the complete logarithm required.

But if the number, whose logarithm is required, be above 10000, then find the logarithm of the two nearest numbers to it that can be found in the table, and say, as their difference : the difference of their logarithms :: the difference of the nearest number and that whose logarithm is required : the difference of their logarithms, nearly; and this difference being added to, or subtracted from, the nearest logarithm, according as it is greater or less than the required one, will give the logarithm required, nearly.

Thus, let it be required to find the logarithm of 367182.

The decimal part of 3671 is by the table .5647844; and of 3672 is .5649027;

∴ The log. of { 367100 is 5.5647844 ; 367200 is 5.5649027 }

Their diff. 100 .0001183 diff.

Nearest No. 367200
Given No. 367182

18 diff.

Therefore 100 : .0001183 :: 18 : .0000212.

And 5.5649027 — .0000212 = 5.5648815 = logarithm of 367182, nearly.

If the number consists both of integers and fractions, or is entirely fractional, find the decimal part of the logarithm as if all its figures were integral; and this, being prefixed to the proper characteristic, will give the logarithm required.

And if the given number is a proper fraction, subtract the logarithm of the denominator from the logarithm of the numerator, and the remainder will be the logarithm sought; which, being that of a decimal fraction, must always have a negative index.

And, if it is a mixed number, reduce it to an improper fraction, and find the difference of the logarithms of the numerator and denominator, in the same manner as before.

In finding the number answering to any given logarithm, the index, if affirmative, will always shew how many integral places the required number consists of; and, if negative, in what place of decimals the first, or significant figure, stands; so that, if the logarithm can be found in the table, the number answering to it will always be had by inspection.

But, if the logarithm cannot be exactly found in the table, find the next greater, and the next less, and then say, As the difference of these two logarithms : the difference of the numbers answering to them :: the difference of the given logarithm, and the nearest tabular logarithm : a fourth number; which added to, or subtracted from, the natural number answering to the nearest tabular logarithm, according as that logarithm is less or greater than the given one, will give the number required, nearly.

Thus, let it be required to find the natural number answering to the logarithm 5.5648815.

The next less and greater logarithms, in the table, are

5.5647844	The numbers	367100
5.5649027	answering	367200
Their diff. .0001183		100

And 5.5649027 — 5.5648815 = .0000212.

Therefore .0001183 : 100 :: .0000212 : 18 nearly.

Whence 367200 — 18 = 377182 = number required.

The Use and Application of Logarithms.—It is evident, from what has been said of the construction of logarithms, that addition of logarithms must be the same thing as multiplication in common arithmetic; and subtraction in logarithms the same as division; therefore, in multiplication by logarithms, add the logarithms of the multiplicand and multiplier together, their sum is the logarithm of the product.

		num.	logarithms.
Example.	Multiplicand	8.5	0.9294189
	Multiplier	10	1.0000000
	Product	85	1.9294189

And in division, subtract the logarithm of the divisor from the logarithm of the dividend, the remainder is the logarithm of the quotient.

		num.	logarithms.
Example.	Dividend	9712.8	3.9873444
	Divisor	456	2.6589648
	Quotient	21.3	1.3283796

To find the Complement of a Logarithm.—Begin at the left hand, and write down what each figure wants of 9, only what the last significant figure wants of 10; so the complement of the logarithm of 456, viz. 2.6589648, is 7.3410352.

In the Rule of Three. Add the logarithms of the second and third terms together, and from the sum subtract the logarithm of the first, the remainder is the logarithm of the fourth. Or, instead of subtracting a logarithm, add its complement, and the result will be the same.

To raise Powers by Logarithms.—Multiply the logarithm of the number given, by the index of the power required, the product will be the logarithm of the power sought.

Example. Let the cube of 32 be required by logarithms. The logarithm of 32 = 1.5051500, which multiplied by 3, is 4.5154500, the logarithm of 32768, the cube of 32. But in raising powers, viz. squaring, cubing, &c. of any decimal fraction by logarithms, it must be observed, that the first significant figure of the power be put so many places below the place of units. as the index of its logarithm wants of 10, 100, &c. multiplied by the index of the power.

To extract the Roots of Powers by Logarithms.—Divide the logarithm of the number by the index of the power, the quotient is the logarithm of the root sought.

To find Mean Proportionals between any two numbers.—Subtract the logarithm of the least term from the logarithm of the greatest, and divide the remainder by a number more by one than the number of means desired; then add the quotient to the logarithm of the least term (or subtract it from the logarithm of the greatest) continually, and it will give the logarithms of all the mean proportionals required.

Example. Let three mean proportionals be sought, between 106 and 100.

Logarithm of 106 = 2.0253059
Logarithm of 100 = 2.0000000

Divide by 4)0.0253059(0.0063264.75

Log. of the least term 100 added		2.0000000
Log. of the 1st mean	101.4673846	2.0063264.75
Log. of the 2d mean	102 9563014	2.0126529.5
Log. of the 3d mean	104.4670483	2.0189794.25
Log. of the greatest term 106.		2.0253059.

LOGIC. The professed business of logic is to explain the nature of the human mind, and the proper manner of conducting its several powers, in order to the attainment of truth and knowledge.

Those, therefore, who have treated expressly of this subject, have endeavoured first to define and describe the several faculties and operations of the human mind, as perception, judgment, memory, invention, &c. They next proceed to lay down rules for correct reasoning and argument. Every act of the judgment they term a *proposition*, and all propositions are either affirmative or negative. All questions or arguments they reduce to syllogisms, that is, from two axioms or propositions (called *terms*, in the technical language) laid down, they deduce a third, or conclusion, and the previous propositions they divide into major and minor. Thus, let the question be, *Whether God is an intelligent being?* Here the major or principal proposition proceeds from the word intelligent, and the minor respects God. They would then arrange the syllogism as follows:

Maj. To dispose things in right and perfect order is the work of an intelligent Being:
Min. But God has disposed creation in right and perfect order;
Conclusion. Therefore God is an intelligent Being.

They next class or arrange the different kinds of syllogisms according to the nature of them. Propositions are not only affirmative and negative, but they are also particular or universal. Hence syllogisms will vary not only as the major or minor proposition is negative or affirmative, but as either is an universal or particular affirmative, &c. Hence they dispose the several kinds of propositions into modes, and the syllogisms into figures, according as they affect the subject or the predicate. The modes are indicated by the letters *a, e, i, o*, as they are affirmative or negative, universal or particular. There are nineteen modes and four figures. The first figure is when the middle term is the subject of the major, and the predicate of the minor: as,

No work of God is bad:
But the natural passions and appetites of men are the work of God;
Therefore they are not bad.

This figure includes four modes, denoted by the words,

"Barbara, celarent, Darii, ferio;"

referring to the vowels which each syllable contains.

The second figure is when the middle term is the predicate of both major and minor: as,

Whatever is bad is not the work of God:
But the natural passions, &c. are the work of God;
Therefore they are not bad.

This figure includes four modes, denoted by the words,

"Cæsare, camestres, festino, baroco."

The third figure is when the middle term is the subject of both major and minor, as,

All Africans are black:
But all Africans are men;
Therefore some men are black.

This figure includes six modes, denoted by the words,

"Darapti, felapton, disamis, datisi, bocardo, ferison."

In the fourth figure it is the predicate of the major, and the subject of the minor, as,

The only being who ought to be worshipped is the Creator of the world:
But the Creator of the world is God;
Therefore God is the only being who ought to be worshipped.

There are five modes of this figure denoted by the words,

"Barbari, Calentes, Dibatis, fessamo, fresisom."

Such is the scheme proposed by the schoolmen as the only guide to truth and wisdom; but how little it has been able to effect may be seen from the labours of those who have practised it most, those very schoolmen themselves. The truth is, if logic is the art of reasoning, the best materials to form a logician, that is a reasoner, are a sound understanding, an extensive and accurate knowledge of facts, and an unprejudiced disposition; and every attempt to reduce the operations of the human mind to mechanical rules, to bring genius to a level with dulness, must be futile and vain. The various terms and figures of logic will be found in their respective places. See MODE.

LOLIUM, *darnel-grass*, a genus of the digynia order, in the triandria class of plants, and in the natural method ranking under the 4th order, gramina. The calyx is monophyllous, fixed, and uniflorous. There are five species. The most remarkable are,

1. The perenne, red darnel, or rye-grass. This is very common in roads and dry pastures. It makes excellent hay upon dry,

chalky, or sandy soils. It is advantageously cultivated along with clover, and springs earlier than other grasses, supplying food for cattle at a time when it is most difficult to be obtained. Cows, horses, and sheep, eat it; goats are not fond of it.

2. The temulentum, or white darnel, grows spontaneously in ploughed fields. If the seeds of this species are malted with barley, the ale soon occasions drunkenness; mixed with bread-corn, they produce but little effect, unless the bread is eaten hot.

LONCHITIS, *spleenwort*, a genus of the cryptogamia filices class of plants, the fructifications of which are arranged into lunulated series, and disposed separately under the sinuses of the leaves. There are five species. The leaves of this plant are of use in healing wounds, and in preventing inflammations of them: they are also used against the spleen. The root is aperient and diuretic.

LONGEVITY, long life. The duration of human life is a subject so universally interesting, that instances of persons who have considerably exceeded the usual term of life have at all times attracted notice, although very few attempts have been made to ascertain the circumstances under which life may be prolonged to its greatest extent. Buffon, Haller, Dr. Fothergill, Dr. Barton, Dr. Hufeland, and a few others who have noticed this subject, appear to have considered but a very small number of the instances of longevity which have occurred. Mr. J. Easton, in order to supply better materials for others, published, a few years since, a much greater collection of instances of this kind, though probably but a small part of what have actually occurred. His list consists of 1712 persons, who are stated to have died at the following ages:

Ages.	Persons.
From 100 to 110 years	1310
110 to 120	277
120 to 130	84
130 to 140	26
140 to 150	7
150 to 160	3
160 to 170	2
170 to 185	3
	1712

Such a number of instances would furnish many useful conclusions; but most accounts of this kind contain little more than the name, age, and place of the death of the person mentioned, from which of course little information can be gained. Sir J. Sinclair, in an Essay on Longevity, has endeavoured to excite a more general interest on this subject, which has by no means been investigated with the attention it deserves.

That longevity depends principally on conformity of conduct to the laws of nature, appears an indisputable fact; but from all the observations which have been made, it likewise appears, that there are other circumstances which have considerable influence: of these perhaps the most certain is descent from long-lived ancestors. Dr Rush, of Philadelphia, remarks, that he has not found a single instance of a person who had lived to be 80 years old, of whom this was not the case; and the accounts collected by others strongly confirm this observation.

The climate of some countries has been supposed to be much more favourable to longevity than others: thus Mr. Whitehurst asserted, that Englishmen in general were longer-lived than North Americans; and Mr. W. Barton has since endeavoured to prove the contrary: but whatever inferences of this kind national partiality may attempt to support, more extensive observations will in general confirm the conclusion, that although longevity evidently prevails more in certain districts than in others, and those regions which lie within the temperate zones are best adapted to promote long life, yet it is by no means confined to any particular nation or climate, as remarkable instances of it may be produced both from very hot and very cold countries. It is highly probable that the human frame is so constituted as to adapt itself easily to the atmosphere and peculiarities of the country in which it receives life, or even into which it is afterwards removed. Thus France and Sweden are countries differing materially in soil and climate: the general mode of life of the inhabitants is likewise very different; yet the usual rate of mortality has been found nearly the same in both. Men can live equally well under very different circumstances. It is sudden changes that are injurious; and temperate climates being less liable to such changes, are found to be most favourable to the continuance of life. There are, however, in almost every country, particular districts more favourable to the health of the inhabitants than others; and the cause of this superiority is chiefly a free circulation of air, uncontaminated with the noxious vapours and exhalations which destroy its purity in other parts; thus hilly districts are almost universally found more healthy than low and marshy places, or than close and crowded cities.

From a list of 145 persons who are recorded to have lived to the age of 120 years and upwards, it appears, that more than half were inhabitants of Great Britain, viz.

63 of England and Wales,
23 of Scotland,
29 of Ireland,
30 of other countries.

The number of instances in Scotland, compared with those of England, appears by this account to have been more than twice the proportion of the population, which certainly seems to shew that the climate of the former is very favourable to long life. The great proportion of inhabitants of Great Britain and Ireland, though perhaps arising in some measure from instances of great age not being so generally noticed and recorded in other places, at least shews, that these countries are not unfavourable to longevity.

It is a fact pretty well established, that more males are born than females; it is also well known, that in almost every form which animal life assumes, the male appears to possess a somewhat superior degree of bodily strength to the female. From these circumstances it might be expected that the number of males living would be found greater than that of the females, and that in general they would enjoy a greater duration of life; the contrary, however, has been asserted, and evidence produced which appeared to justify such an opinion; but it seems probable, that in forming the accounts from which the number of females living appeared greater than that of the males, sufficient attention was not paid to the number of males engaged chiefly abroad in the army and navy, and of the emigrations to foreign parts being chiefly of males. That the male constitution is naturally more durable than that of females, may be inferred from the list before referred to of 145 persons, who have attained unusually great age, more than two-thirds of the number being males. Dr. Hufeland remarks, that the equilibrium and pliability of the female body seems, for a certain time, to give it more durability, and to render it less susceptible of injury from destructive influences than that of men; but that male strength is, without doubt, necessary to arrive at a very great age. More women, therefore, become old, but fewer very old; and if the registers of mortality, from which tables of the probability of the duration of human life are formed, were more extensive, and comprehended a greater number of years, so as to include the instances of great longevity, the difference between the value of male and female lives would appear less than it is supposed to be, and probably the sum of life of the whole of each sex approaches very nearly to equality.

The form of the individual appears to be of considerable importance: moderate-sized and well-proportioned persons have certainly the best chance of long life. There are, however, a few instances of persons of a different description having attained considerable age. Mary Jones, who died in 1783, at Wern, in Shropshire, aged 100 years, was only two feet eight inches in height, very deformed and lame; and James M'Donald, who died near Cork in the year 1760, aged 117, was seven feet six inches high.

Matrimony, if not entered into too early, appears to be very conducive to health and long life, the proportion of unmarried persons attaining great age, being remarkably small; Dr. Rush says, that in the course of his enquiries, he met with only one person beyond eighty years of age, who had never been married. This is a very limited remark; Mrs. Malton, who died in 1733, aged 105; Ann Kerney, who died the same year, aged 110; Martha Dunridge, who died in 1752, in the 100th year of her age; and Mrs. Warren, who died in 1753, aged 104, had never been married: and in the list prefixed to sir John Sinclair's Essay on Longevity, of pensioners in Greenwich hospital, who were upwards of eighty years of age, there are sixteen who never were married: the same list, however, contains five times as many persons who had been married, and other accounts are in a still greater proportion.

The Chinese erect triumphal or honorary arches to the memory of persons who have lived a century, thinking, that without a sober and virtuous life it is impossible to attain so great an age. Temperance is certainly the best security of health; and no man can reasonably expect to live long who impairs the vital powers by excess, which converts the most natural and beneficial enjoyments into the most certain means of destruction. The few instances of individuals who, notwithstanding their licentious mode of life, have attained considerable age, cannot be put in comparison with the immense number whose lives have been materially shortened by such indulgences. Dr. Fothergill observes, that "the due regulation of the passions perhaps contributes more to health and longevity than any of the other nonnaturals."

The cheerful and contented are certainly more likely to enjoy good health and long life than persons of irritable and fretful dispositions; therefore whatever tends to promote good humour and innocent hilarity, must have a beneficial influence in this respect; and persons whose attention is much engaged on serious subjects should endeavour to preserve a relish for cheerful recreations.

LONGITUDE *of a star*, in astronomy, an arch of the ecliptic, intercepted between the beginning of Aries and the point of the ecliptic cut by the star's circle of longitude.

LONGITUDE *of a place*. See GEOGRAPHY.

LONGITUDE, in navigation, the distance of a ship or place, east or west, from another, reckoned in degrees of the equator.

As the discovery of a method to find the longitude would render voyages safe and expeditious, and also preserve ships and the lives of men, the following rewards have been offered as an encouragement to any person who shall discover a proper method for finding it out:—In the year 1714, the British parliament offered a reward for the discovery of the longitude: the sum of 10,000*l.* if the method determined the longitude to 1° of a great circle, or to 60 geographical miles; of 15,000*l.* if it determined it to 40 miles; and of 20,000*l.* if it determined it to 30 miles; with this proviso, that if any such method extend no further than 30 miles adjoining to the coast, the proposer should have no more than half the rewards. The act also appoints the first lord of the admiralty, the speaker of the house of commons, the first commissioner of trade, the admirals of the red, white, and blue squadrons, the master of the Trinity-house, the president of the royal society, the royal astronomer at Greenwich, the two Savilian professors at Oxford, and the Lucasian and Plumian professors at Cambridge, with several other persons, as commissioners for the longitude at sea. The Lowndian professor at Cambridge was afterwards added. After this act of parliament, several other acts passed in the reigns of George II. and III. for the encouragement of finding the longitude. At last, in 1774, an act passed, repealing all other acts, and offering separate rewards to any person who should discover the longitude, either by the watch keeping true time within certain limits, or by the lunar method, or by any other means. The act proposes as a reward for a timekeeper, the sum of 5000*l.* if it determine the longitude to 1° or 60 geographical miles; the sum of 7500*l.* if it determine it to 40 miles; and the sum of 10,000*l.* if it determine it to 30 miles, after proper trials specified in the act. If the method is by improved solar and lunar tables, constructed upon sir Isaac Newton's theory of gravitation, the author shall be entitled to 5000*l.* if such tables shall show the distance of the moon from the sun and stars, within fifteen seconds of a degree, answering to about seven minutes of longitude, after allowing half a degree for the errors of observation. And for any other method, the same rewards are offered as those for timekeepers, provided it gives the longitude true within the same limits, and is practicable at sea. The commissioners have also a power of giving smaller rewards, as they shall judge proper, to any one who shall make any discovery for finding the longitude at sea, though not within the above limits; provided, however, that if such person or persons shall afterwards make any further discovery as to come within the above-mentioned limits, such sum or sums as they may have received shall be considered as part of such greater reward, and deducted therefrom accordingly.

To find the longitude by a time-keeper. The sun appears to move round the earth from east to west, or to describe 360°, in 24 hours, and therefore he appears to move 15° in an hour. If therefore the meridians of two places make an angle of 15° with each other, or if the two places differ 15° in longitude, the sun will come to the eastern meridian one hour before he comes to the western meridian, and therefore when it is twelve o'clock at the former place, it is only eleven at the latter; and in general, the difference between the times by the clock at any two places, will be the difference of their longitudes, converted into time at the rate of 15° for an hour, the time at the eastern place being the forwardest. If, therefore, we can tell what o'clock it is at any two places at the same instant of time, we can find the difference of their longitudes, by allowing 15° for every hour that the clocks differ.

Let, therefore, the timekeeper be well regulated and set to the time at Greenwich, that being the place from which we reckon our longitude; then if the watch neither gains nor loses, it will always show the time at Greenwich, wherever you may be. Now to find the time by the clock at any other place, take the sun's altitude, and thence find the time; now the time thus found is apparent time, or that found by the sun, which differs from the time shown by the clock by the equation of time. We must, therefore, apply the equation of time to the time found by the sun, and we shall get the time by the clock; and the difference between the time by the clock so found, and the time by the timekeeper, or the time at Greenwich, converted into degrees at the rate of 15° for an hour, gives the longitude of the place from Greenwich. For example: let the time by the timekeeper, when the sun's altitude was taken, be 6h. 19′, and let the time deduced from the sun's altitude be 9h. 27′, and suppose at that time the equation of time to be 7′, showing how much the sun is that day behind the clock, then the time by the clock is 9h. 34′, the difference between which and 6h. 19′, is 3h. 15′; and this converted into degrees, at the rate of 15° for 1 hour, gives 48° 45′, the longitude of the place from Greenwich; and as the time is forwarder than that at Greenwich, the place lies to the east of Greenwich. Thus the longitude could be very easily determined, if you could depend upon the timekeeper. But as a watch will always gain or lose, before the timekeeper is sent out, its gaining or losing every day for some time, a month for instance, is observed; this is called the rate of going of the watch, and from thence the mean rate of going is thus found:

Suppose I examine the rate of a watch for 30 days; on some of those days I find it has gained, and on some it has lost; add together all the quantities it has gained, and suppose they amount to 17″; add together all the quantities it has lost, and suppose they amount to 13″; then upon the whole, it has gained 4″ in 30 days; and this is called the mean rate for that time; and this divided by 30, gives 0″,133 for the mean daily rate of gaining; so that if the watch had gained regularly 0″,133 every day, at the end of the 30 days it would have gained just as much as it really did gain, by sometimes gaining and sometimes losing. Or you may get the mean daily rate thus: Take the difference between what the clock was too fast or too slow on the first and last days of observation, if it be too fast or too slow on each day; but take the sum, if it is too fast on one day and too slow on the other, and divide by the number of days between the observations, and you get the mean daily rate. Thus, if the watch was too fast on the first day 18″, and too fast on the last day 32″, the difference 14″ divided by 30, gives 0″,466, the mean daily rate of gaining. But if the watch was too fast on the first day 7″, and too slow on the last day 10″, the sum 17″ divided by 30, gives 0″,566, the mean daily rate of losing. After having thus got the mean daily rate of gaining or losing, and knowing how much the watch was too fast or too slow at first, you can tell, according to that rate of going, how much it is too fast or too slow at any other time. In the first case, for instance, let the watch have been 1′ 17″ too fast at first, and I want to know how much it is too fast 50 days after that time: now it gains 0″,133 every day; if this is multiplied by 50, it gives 6″,65 for the whole gain in 50 days; therefore, at the end of that time, the watch would be 1′. 23″,65 too fast. This would be the error, if the watch continued to gain at the above rate; and although, from the different temperatures of the air, and the imperfection of the workmanship, this cannot be expected, yet the probable error will by this means be diminished, and it is the best method we have to depend upon. In watches which are under trial at the Royal Observatory at Greenwich, as candidates for the rewards, this allowance of a mean rate is admitted, although it is not mentioned in the act of parliament: the commissioners, however, are so indulgent as to grant it, which is undoubtedly favourable to the watches.

As the rate of going of a watch is subject to vary from so many circumstances, the observer, whenever he goes ashore, and has sufficient time, should compare his watch for several days with the true time found by the sun, by which he will be able to find its rate of going. And when he comes to a place whose longitude is known, he may then set his watch to Greenwich time; for when the longitude of a place is known, you know the difference between the time there and at Greenwich. For instance, if he go to a place known to be 30° east longitude from Greenwich, his watch should be two hours slower than the time at that place. Find therefore the true time at that place, by the sun, and if the watch is two hours slower, it is right; if not, correct it by the difference, and it again gives Greenwich time.

In the year 1726, Mr. John Harrison produced a timekeeper of his own construction, which did not err above one second in a month for ten years together; and in the year 1736 he had a machine tried in a voyage to and from Lisbon, which was the means of correcting an error of almost a degree and a half in the computation of the ship's reckoning. In consequence of this success, Mr. Harrison received public encouragement to proceed, and he made three other timekeepers, each more accurate than the former, which were finished successively in the years 1739, 1758, and 1761; the last of which proved so much to his own satisfaction, that he applied to the commissioners of the longitude to have this instrument tried in a voyage to some port in the West Indies, according to the directions of the statute of the 12th of Anne above cited. Accordingly, Mr. William Harrison, son of the inventor, embarked in November 1761, on a voyage for Jamaica, with this fourth timekeeper or watch; and on his arrival there, the longitude, as shewn by the timekeeper, differed but one geographical mile and a quarter from the true longitude, deduced from astronomical observations. The same gentleman returned to England with the timekeeper, in March 1762, when he found that it had erred in the four months, no more than $1' 54''\frac{1}{2}$ in time, or $28\frac{5}{8}$ minutes of longitude; whereas the act requires no greater exactness than 30 geographical miles, or minutes of a great circle, in such a voyage. Mr. Harrison now claimed the whole reward of 20,000*l.* offered by the said act: but some doubts arising in the minds of the commissioners concerning the true situation of the island of Jamaica, and the manner in which the time at that place had been found, as well as at Portsmouth; and it being farther suggested by some, that although the timekeeper happened to be right at Jamaica, and after its return to England, it was by no means a proof that it had been always so in the intermediate time; another trial was therefore proposed, in a voyage to the island of Barbadoes, in which precautions were taken to obviate as many of these objections as possible. Accordingly the commissioners previously sent out proper persons to make astronomical observations on that island, which, when compared with other corresponding ones made in England, would determine, beyond a doubt, its true situation; and Mr. William Harrison again set out with his father's timekeeper, in March 1764, the watch having been compared with equal altitudes at Portsmouth before he set out, and he arrived at Barbadoes about the middle of May; where, on comparing it again by equal altitudes of the sun, it was found to shew the difference of longitude between Portsmouth and Barbadoes to be 3h. 55m. 3s.; the true difference of longitude between these places, by astronomical observations, being 3h. 54m. 20s.; so that the error of the watch was 43s., or $10' 45''$ of longitude. In consequence of this and the former trials, Mr. Harrison received one moiety of the reward offered by the 12th of queen Anne, after explaining the principles on which his watch was constructed, and delivering this, as well as the three former, to the commissioners of the longitude for the use of the public: and he was promised the other moiety of the reward, when other timekeepers should be made on the same principles, either by himself or others, performing equally well with that which he had last made. In the mean time, this last timekeeper was sent down to the Royal Observatory at Greenwich, to be tried there under the direction of the Rev. Dr. Maskelyne, the astronomer-royal. But it did not appear, during this trial, that the watch went with the regularity that was expected; from which it was apprehended that the performance even of the same watch was not at all times equal; and consequently that little certainty could be expected in the performance of different ones. Moreover the watch was now found to go faster than during the voyage to and from Barbadoes by 18 or 19 seconds in 24 hours; but this circumstance was accounted for by Mr. Harrison, who informs us that he had altered the rate of its going by trying some experiments, which he had not time to finish before he was ordered to deliver up the watch to the board. Soon after this trial, the commissioners of longitude agreed with Mr. Kendal, one of the watch-makers appointed by them to receive Mr. Harrison's discoveries, to make another watch on the same construction with this, to determine whether such watches could be made from the account which Mr. Harrison had given, by other persons as well as himself. The event proved the affirmative; for the watch produced by Mr. Kendal, in consequence of this agreement, went considerably better than Mr. Harrison's did. Mr. Kendal's watch was sent out with captain Cook, in his second voyage towards the south pole and round the globe, in the years 1772, 1773, 1774, and 1775; when the only fault found in the watch was, that its rate of going was continually accelerated; though in this trial of three years and a half it never amounted to $14''\frac{1}{2}$ a day. The consequence was, that the house of commons, in 1774, to whom an appeal had been made, were pleased to order the second moiety of the reward to be given to Mr. Harrison, and to pass the act above-mentioned. Mr. Harrison had also at different times received some other sums of money, as encouragements to him to continue his endeavours, from the board of longitude, and from the India company, as well as from many individuals. Mr. Arnold and some other persons have since also made several very good watches for the same purpose, and have been remunerated for their skill and labour.

Others have proposed various astronomical methods for finding the longitude. These methods chiefly depend on having an ephemeris or almanac suited to the meridian of some place, as Greenwich for instance, to which the Nautical Almanac is adapted, which shall contain for every day computations of the times of all remarkable celestial motions and appearances, as adapted to that meridian. So that if the hour and minute is known when any of the same phenomena are observed in any other place whose longitude is desired, the difference between this time and that to which the time of the said phenomenon was calculated and set down in the almanac, will be known, and consequently the difference of longitude also becomes known between that place and Greenwich, allowing at the rate of fifteen degrees to an hour.

Now it is easy to find the time at any place, by means of the altitude or azimuth of the sun or stars, which time it is necessary to find by such means, both in these astronomical modes of determining the longitude, and in the former by a timekeeper; and it is the difference between that time, so determined, and the time at Greenwich, known either by the timekeeper or by the astronomical observations of celestial phenomena, which gives the difference of longitude at the rate above-mentioned. Now the difficulty in these methods lies in the fewness of proper phenomena, capable of being thus observed; for all slow motions, such as belong to the planet Saturn, for instance, are quite excluded, as affording too small a difference, in a considerable space of time, to be properly observed; and it appears that there are no phenomena in the heavens proper for this purpose, except the eclipses or motions of Jupiter's satellites, and the eclipses or motions of the moon, viz. such as her distance from the sun or certain fixed stars lying near her path, or her longitude or place in the zodiac, &c. Now of these methods,

1st. That by the eclipses of the moon is very easy, and sufficiently accurate, if they did but happen often, as every night. For at the moment when the beginning or middle or end of an eclipse is observed by a telescope, there is no more to be done but to determine the time by observing the altitude or azimuth of some known star; which time being compared with that in the tables, set down for the happening of the same phenomenon at Greenwich, gives the difference in time, and consequently of longitude sought. But as the beginning or end of an eclipse of the moon cannot generally be observed nearer than one minute, and sometimes two or three minutes of time, the longitude cannot certainly be determined by this method, from a single observation, nearer than one degree of longitude. However, by two or more observations, as of the beginning and end, &c. a much greater degree of exactness may be attained.

2d. The moon's place in the zodiac is a phenomenon more frequent than her eclipses; but then the observation of it is difficult, and the calculus perplexed and intricate, by reason of two parallaxes; so that it is hardly practicable to any tolerable degree of accuracy.

3d. But the moon's distances from the sun or certain fixed stars, are phenomena to be observed many times in almost every night, and afford a good practical method of determining the longitude of a ship at almost any time; either by computing from thence the moon's true place, to compare with the same in the almanac; or by comparing her observed distance itself with the same as there set down.

From the great improvements made by Newton in the theory of the moon, and more lately by Euler and others on his principles, professor Mayer, of Gottingen, was enabled to calculate lunar tables more correct than any former ones; having so far succeeded as to give the moon's place within one minute of the truth, as has been proved by a comparison of the tables with the observations made at the Greenwich observatory by Dr. Bradley, and by Dr. Maskelyne, the late astronomer-royal; and the same have been still farther improved under his direction, by the late Mr. Charles Mason, by several new equations, and the whole computed to tenths of a second. These tables, when compared with the above-mentioned series of observations, a proper allowance being made for the unavoidable error of observation, seem to give always the moon's longitude in the heavens correctly within 30 seconds of a degree; which greatest error, added to a possible error of one minute in taking the moon's distance from the sun or a star at sea, will at a medium only produce an error of 42 minutes of longitude. To facilitate the use of the tables, Dr. Maskelyne proposed a nautical ephemeris, the scheme of which was adopted by the commissioners of longitude, and first executed in the year 1767, since which time it has been regularly continued. But as the rules that were given in the appendix to one of those publications, for correcting the effects of refraction and parallax, were thought too difficult for general use, they have been reduced to tables. So that, by the help of the ephemeris, these tables, and others that are also provided by the board of longitude, the calculations relating to the longitude, which could not be performed by the most expert mathematician in less than four hours, may now be completed with great ease and accuracy in half an hour.

As this method of determining the longitude depends on the use of the tables annually published for this purpose, those who wish for farther information are referred to the instructions that accompany them, and particularly to those that are annexed to the tables requisite to be used with the Astronomical and Nautical Ephemeris.

4th. The phenomena of Jupiter's satellites have commonly been preferred to those of the moon, for finding the longitude; because they are less liable to parallaxes than these are, and besides they afford a very commodious observation whenever the planet is above the horizon. Their motion is very swift, and must be calculated for every hour.

Now, to find the longitude by these satellites: with a good telescope observe some of their phenomena, as the conjunction of two of them, or of one of them with Jupiter, &c. and at the same time find the hour and minute, from the altitudes of the stars, or by means of a clock or watch, previously regulated for the place of observation; then, consulting tables of the satellites, observe the time when the same appearance happens in the meridian of the place for which the tables are calculated; and the difference of time, as before, will give the longitude.

The eclipses of the first and second of Jupiter's satellites are the most proper for this purpose; and as they happen almost daily, they afford a ready means of determining the longitude of places at land, having indeed contributed much to the modern improvements in geography; and if it were possible to observe them with proper telescopes, in a ship under sail, they would be of great service in ascertaining its longitude from time to time. To obviate the inconvenience to which these observations are liable from the motions of the ship, Mr. Irwin invented what he called a marine chair: this was tried by Dr. Maskelyne, in his voyage to Barbadoes, when it was found that no benefit could be derived from the use of it. And indeed, considering the great power requisite in a telescope proper for these observations, and the violence as well as irregularities in the motion of a ship, it is to be feared that the complete management of a telescope on shipboard will always remain among the desiderata in this part of nautical science. And farther, since all methods that depend on the phenomena of the heavens, have also this other defect, that they cannot be observed at all times, this renders the improvement of timekeepers of the greater importance.

LONICERA, *honeysuckle*, a genus of the monogynia order, in the pentandria class of plants. The corolla is monopetalous and irregular; the berry polyspermous, bilocular, and inferior. There are 19 species, of which the most remarkable are,

1. The alpigena, or upright red-berried honeysuckle, rises with a shrubby, short, upright stem, four or five feet high.

2. The cærulea, or blue-berried honeysuckle, with a shrubby upright stem, three or four feet high, and many white flowers proceeding from the sides of the branches.

3. The nigra, or black-berried upright honeysuckle, with a shrubby stem three or four feet high, and white flowers succeeded by single and distinct black berries.

4. The tartarica, or Tartarian honeysuckle, with a shrubby upright stem, three or four feet high, heart-shaped opposite leaves, and whitish erect flowers succeeded by red berries, sometimes distinct, and sometimes double.

5. The diervilla, or yellow-flowered Arcacadian honeysuckle, with shrubby upright stalks, to the height of three or four feet, and clusters of pale yellow flowers, appearing in May and June, and sometimes continuing till autumn, but rarely ripening seeds here.

6. The xylosteum, or fly honeysuckle, with a strong shrubby stem, branching erect to the height of seven or eight feet, and erect white flowers proceeding from the sides of the branches.

7. The symphoricarpos, or shrubby St. Peter's-wort, with a shrubby rough stem, four or five feet high, and small greenish flowers.

8. The periclymenum, or common climbing honeysuckle, has two principal varieties, viz. the English wild honeysuckle, or woodbine of our woods and hedges, and the Dutch or German honeysuckle, with a shrubby declinated stalk, and long trailing purplish branches, furnishing large beautiful red flowers of a fragrant odour, appearing in June and July.

9. The caprifolium, or Italian honeysuckle, with shrubby declinated stalks, sending out long slender trailing branches, terminated by verticillate or whorled bunches of close-sitting flowers, very fragrant, and white, red, and yellow colours.

10. The sempervirens, or evergreen trumpet-flowered honeysuckle, with a shrubby declinated stalk, sending out long slender trailing branches, terminated by naked verticillate spikes, of long, unreflexed, deep-scarlet flowers, very beautiful, but of little fragrance.

LOOF, in the sea language, is a term used in various senses; thus the loof of a ship is that part of her aloft which lies just before the chest-tree; hence the guns which lie there are called loof-pieces: keep your loof, signifies, keep the ship near to the wind: to loof into a harbour, is to sail into it close by the wind: loof up, is to keep nearer the wind: to spring the loof, is when a ship that was going large before the wind, is brought close by the wind.

Loof-tackle, is a tackle in a ship which serves to lift goods of small weight in or out of her.

LOOKING-GLASSES. See Optics.

LOOM, the weaver's frame, a machine whereby several distinct threads are woven into one piece. Looms are of various structures, accommodated to the various kinds of materials to be woven, and the various manner of weaving them, viz. for woollens, silks, linens, cottons, cloths of gold, and other works, as tapestry, ribands, stockings, &c. See Weaving.

The weaver's loom-engine, otherwise called the Dutch loom-engine, was brought into use from Holland to London, in or about the year 1676.

The lower compartment of Plate Lock and Loom, represents a loom for weaving silks or other plain work. A, fig. 6, is a roll called the cloth-beam, on which the cloth is wound as it is wove; at one end it has a racket-wheel *a*, and a click to prevent its running back; at the same end it has also four holes in it, and is turned by putting a stick in these holes: at the other end of the loom is another roll B, on which the yarn is wound; this has two small cords *bb* wrapped round it, the ends of which are attached to a bar *d*, which has a weight D hung to it; by this means a friction is caused, which prevents the roll B turning by accident. EF are called lambs; they are composed of two sticks *efhi*, between which are fastened a great number of threads; to the bar *e* are fastened two cords *gh*, which pass over pulleys, and are fastened to the bar *h* of the lamb F; the lower bars of each lamb are connected by cords with the treadles GH; the workman sits on the seat K, and places his feet upon these treadles; as they are connected together by the cords *gh*, when he presses down one, it will raise the other, and the lambs with them; a great number of threads, according to the width of the cloth, are wound round the yarn-beam B, and are stretched to the cloth-beam A; the middle of the threads which compose the lamb EF, have loops (called eyes) in them, through which the threads between the rolls AB, which are called the warp, are passed; the first thread of the warp goes through the loops of the lambs E, the next attached to the lamb F, and so on alternately; by this means, when the weaver presses down one of the treadles with his foot, and raises the other, one lamb draws up every other thread, and the other sinks all the rest, so as to make an opening between the sets of thread: LL is a frame moving on a centre at the top of the frame of the loom; the lower part of this frame is shewn in fig. 8; LL are the two uprights of the frame, *l* is the bar that connects them, M is a frame carrying a great number of pieces of split reed or sometimes fine wire at equal distances; between these the threads of the warp are passed; the frame M is supported by a piece of wood *m* called the shuttle-race, which is fastened into the front of the pieces LL; each end of this piece has boards nailed to the sides, so as to form troughs NO; at a small distance above these are fixed two very smooth wires *no*; their use is to guide the two pieces *pq*, call-peckers or drivers; to each of these pieces a string is fastened, and these strings are tied to a piece of wood P, which the weaver holds in his hand, and by snatching the stick to either side, draws the pecker forwards very quick, and gives the shuttle, fig. 7. (which is to be laid in the trough before the pecker) a smart blow, and drives it along across the race *m* into the other trough, where it pushes the pecker along to the end of the wire, ready for the next stroke which throws it back again, and so on. Fig. 7. represents the under side of the shuttle on a larger scale; its ends are pointed with iron; it has a large mortise through the middle of it, in which is placed a quill *a* containing the yarn; *b* is a piece of glass, called the eye of the shuttle, with a hole in it, through which comes the end of the thread; *dd* are two small wheels to make it run easily on the race. The operations are as follow: the workman sitting upon the seat K, holds the stick P in his right hand, and takes hold of one of the bars of the frame LL with his left; presses his foot on one of the treadles GH, which by means of the lambs EF, as before described, divides the warp; he then snatches the stick P, and by that means throws the shuttle, fig. 7, which unwinds the thread in it, and leaves it lying in between the threads of the warp; he then relieves the treadle he before kept down, and presses down the other; while he is doing this, he with his left hand draws the frame LL towards him, and then returns it. The use of this is to beat the last thread thrown by the shuttle close up to the one that was thrown before it by the split reeds M, fig. 8. As soon as he has brought the frame LL back to its original position, and again divided the warp by the treadle, he throws the shuttle again: when he has in this manner finished about 12 or 14 inches of cloth, he winds it up by turning the roll A with the stick, as before described. Some very expert weavers will throw the shuttle and perform the other operations at the rate of 120 times per minute.

Loom, in the sea language. When a ship appears big when seen at a distance, they say she looms.

Loom-gale, a gentle easy gale of wind, in which a ship can carry her topsails atrip.

LOOP, in the iron works, denotes a part of a sow or block of cast iron, broken or melted off from the rest.

LOPHIUS, *fishing-frog*, *toad-fish*, or *sea-devil*, a genus of the branchiostegious order of fishes, whose head is in size equal to all the rest of the body. There are three species, the most remarkable of which is the piscatorius, or common fishing-frog, an inhabitant of the British seas. This singular fish grows to a large size, some being between four and five feet in length; and Mr. Pennant mentions one taken near Scarborough, whose mouth was a yard wide. The fishermen on that coast have a great regard for this fish, from a supposition that it is a great enemy to the dog-fish; and whenever they take it with their lines, set it at liberty. The head of this fish is much larger than the whole body, is round at the circumference, and flat above; the mouth of a prodigious wideness. The under jaw is much longer than the upper; the jaws are full of slender sharp teeth; in the roof of the mouth are two or three rows of the same. On each side the upper jaw are two sharp spines, and others are scattered about the upper part of the head. The body grows slender near the tail, the end of which is quite even. The colour of the upper part of this fish is dusky; the lower part white; the skin smooth.

LORANTHUS, a genus of the monogynia order, in the hexandria class of plants, and in the natural method ranking under the 48th order, aggregatæ. The germen is inferior; there is no calyx; the corolla is sexfid and revoluted; the stamina are at the tops of the petals; the berry is monospermous. There are 18 species, natives of America.

LORD. See Peer.

LORD'S DAY. All persons not having a reasonable excuse, shall resort to their parish church or chapel (or some congregation of religious worship allowed by the toleration act) on every Sunday, on pain of punishment by the censures of the church, and of forfeiting 1*s*. to the poor for every offence; to be levied by the churchwardens by distress, by warrant of one justice.

The hundred shall not be answerable for any robbery committed on the Lord's day.

No carrier shall travel, or drover drive cattle, on the Lord's day, under the penalty of 20*l*.

No person upon the Lord's day shall serve or execute any writ, process, warrant, order, judgment, or decree (except in cases of treason, felony, or breach of the peace), but the service thereof shall be void.

LOTTERIES are declared to be public nuisances, 5 Geo. I. c. 9.; but for the public service of the government, lotteries are frequently established by particular statutes, and managed by special officers and persons appointed.

By stat. 42 Geo. III. c. 54, lottery-office keepers are to pay 50*l*. for every licence in London, Edinburgh, and Dublin, or within 20 miles of either, and 10*l*. for every licence for every other office; and licensed persons shall deposit 30 tickets with the receiver-general of the stamp-duties, or licence to be void.

By stat. 22 Geo. III. c. 47, lottery-office keepers must take out a licence; and offices are to be open only from eight in the morning to eight in the evening, except the Saturday evening preceding the drawing. The sale of chances and shares of tickets, by persons not being proprietors thereof, is prohibited under penalty of 50*l*.; and by 42 Geo. III. c. 119, all games or lotteries called *little goes*, are declared public nuisances, and all persons keeping any office or place for any game or lottery, not authorized by law, shall forfeit 500*l*. and be deemed rogues and vagabonds. The proprietor of a whole ticket may nevertheless insure it for its value only, with any licensed office for the whole time of drawing from the time of insurance, under a bona fide agreement without a stamp.

LOTUS, or *bird's-foot trefoil*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The legumen is cylindrical, and very erect, the alæ closing upwards longitudinally; the calyx is tubulated. There are 23 species, but only five or six are usually cultivated in our gardens.

1. The siliquosus, or winged pea, has trailing, slender, branchy stalks, about a foot long, with trifoliate oval leaves, and from the axillas of the branches, large, papilionaceous, red flowers, one on each footstalk, succeeded by tetragonous solitary pods, having a membranous wing or lobe, running longitudinally at each corner. It flowers in June and July, and the seeds ripen in autumn. 2. The creticus, or Cretan silvery lotus. 3. The Jacobæus, or black lotus of St. James's island. 4. The hirsutus, or hairy Italian lotus. 5. The dorcynium, white Austrian lotus, or shrub trefoil of Montpelier. 6. The edulis, with yellow flowers.

The first species is a hardy annual. The other species may be propagated either by seeds or cuttings, but require to be kept in pots in the greenhouse during the winter season.

LOUIS, or Knights of St. Louis, the name of a military order in France, instituted by Louis XIV. in 1693.

LOUSE. See Pediculus.

LOXIA, a genus of birds of the order of passeres, the distinguishing characters of which are: the bill is strong, convex above and below, and very thick at the base; the nostrils are small and round; the tongue is as if cut off at the end; the toes are four, placed three before and one behind, excepting one species, which has only two toes before and one behind. The most remarkable are:

1. The curvirostra, or common cross-bill, is about the size of a lark, is known by the singularity of its bill, both mandibles of which curve opposite ways and cross each other: the general colour of the plumage in the male is of a red-lead, inclining to rose-colour, and more or less mixed with brown; the wings and tail are brown; the legs black. The female is of a green colour, more or less mixed with brown in those parts where the male is red. This species is a constant inhabitant of Sweden, Germany, Poland, Switzerland, Russia, and Siberia, where it breeds; but migrates sometimes in vast flocks into other countries, as is now and then the case in respect to England; for though in some years a few are met with, yet in others it has been known to visit us by thousands, fixing on such spots as are planted with pines, for the sake of the seeds, which are its natural food: it is observed to hold the cone in one claw like the parrot, and to have all the actions of that bird when kept in a cage. It is also found in North America and Greenland; and is said to make its nest in the highest parts of the fir-trees, fastening it to the branch with the resinous matter which exsudes from the trees.

2. The coccothraustes, or hawfinch, is in length seven inches. This species is ranked among the British birds; but only visits these kingdoms occasionally, and for the most part in winter, and is never known to breed here. It is more plenty in France. It feeds on berries, kernels, &c. and from the great strength of the bill, it cracks the stones of the fruit of the haws, cherries, &c. with the greatest ease.

3. The pyrrhula, or bullfinch, is so generally known as almost to supersede description. This species is common in most parts of the continent of Europe, and throughout Russia and Siberia, at which last places it is caught for the table. In winter it approaches gardens and orchards, and has been generally stigmatised for making havock among the buds of trees. From some late observations, however, it would appear, that the object of these birds is not the bud, but "the worm in the bud;" and that this species, in conjunction with various other species of small birds, are the frequent means of defending the embryo fruits, and thence promoting their growth to maturity; for the warmth that swells the buds, not only hatches eggs of unnumbered tribes of insects, whose parent flies, by an unerring instinct, laid them there, but brings forward a numerous race already in a caterpillar state, that now issue from their concealments, and make their excursion along the budding branches, and would probably destroy every hope of fruitage, but for those useful instruments for its preservation, whose young are principally fed by eating caterpillars. The bullfinch, in its wild state, has only a plain note; but when tamed, it becomes remarkably docile, and may be taught any tune after a pipe, or to whistle any notes in the best manner; it seldom forgets what it has learned; and will become so tame as to come at call, perch on its master's shoulders, and (at command) go through a difficult musical lesson. They may be also taught to speak, and some thus instructed are annually brought to London from Germany.

4. The cardinalis, or cardinal grossbeak, is near eight inches in length. The bill is stout, and of a pale-red colour; the irides are hazel; the head is greatly crested, the feathers rising up to a point when erect; round the bill, and on the throat, the colour is black: the rest of the bird of a fire-red. The female differs from the male, being mostly of a reddish brown. This species is met with in several parts of North America, and has attained the name of Virginia nightingale, from the fineness of its song, the note of which resembles that of the nightingale.

5. The orix, or grenadier grossbeak, is about the size of a house-sparrow. The forehead, sides of the head, and chin, are black; the breast and belly the same; the wings are brown, with pale edges; and the rest of the body of a beautiful red colour. These birds are inhabitants of Saint Helena; they are also in plenty at the Cape of Good Hope, where they frequent watery places that abound with reeds, and among which they are supposed to make their nest. If, as is supposed, this is the same with Kolben's finch, he says that the nest is of a peculiar contrivance, made with small twigs, interwoven very closely and tightly with cotton, and divided into two apartments with but one entrance, the upper for the male, the lower for the female, and is so tight as not to be penetrated by any weather. He adds, that the bird is scarlet only in summer, being in the winter wholly ash-coloured. These birds, seen among the green reeds, are said to have a wonderful effect: for, from the brightness of their colours, they appear like so many scarlet lilies. See Plate Nat. Hist. fig. 253.

6. The pensilis, or pensile grossbeak, (the toddy-bird of Fryer) is about the size of the house-sparrow: the bill is black; the irides are yellow; the head, throat, and fore-part of the neck, the same; from the nostrils springs a dull green stripe, which passes through the eye and beyond it, where it is broader; the hind part of the head and neck, the back, rump, and wing-coverts, are of the same colour; the quills are black, edged with green; the belly is deep grey, and the vent of a rufous red; the tail and legs are black. This species is found at Madagascar; and fabricates a nest of a curious construction, composed of straw and reeds interwoven in shape of a bag, the opening beneath. It is fastened above to a twig of some tree; mostly to those growing on the borders of streams. On one side of this, within, is the true nest. The bird does not form a new nest every year, but fastens a new one to the end of the last; and often as far as five in number, one hanging from another. These build in society, like rooks, often five or six hundred being seen on one tree. They have three young at each hatch. See Plate Nat. Hist. fig. 254.

7. The bengalensis, or Bengal gros-beak, is a trifle bigger than a house-sparrow. The female lays three or four eggs.

8. The socia, or sociable grossbeak, is about the size of a bullfinch; the general colour of the body above is a rufous brown, the under parts yellowish. It inhabits the interior country at the Cape of Good Hope, where it was discovered by colonel Paterson. These birds, according to our author, live together in large societies, and their mode of nidification is extremely uncommon. They build in a species of mimosa which grows to an uncommon size. In one described by col. Paterson, there could be no less a number than from 800 to 1000 residing under the same roof. He calls it a roof, because it perfectly resembles that of a thatched house; and the ridge forms an angle so acute and so smooth, projecting over the entrance of the nest below, that it is impossible for any reptile to approach them. The industry of these birds "seems almost equal (says our author) to that of the bee: throughout the day they appear to be busily employed in carrying a fine species of grass, which is the principal material they employ for the purpose of erecting this extraordinary work, as well as for additions and repairs. Though my short stay in the country was not sufficient to satisfy me by ocular proofs, that they added to their nest as they annually increased in numbers, still from the many trees which I have seen borne down with the weight, and others which I have observed with their boughs completely covered over, it would appear that this is really the case. When the tree which is the support of this aerial city is obliged to give way to the increase of weight, it is obvious that they are no longer protected, and are under the necessity of rebuilding in other trees. One of these deserted nests I had the curiosity to break down, so as to inform myself of the internal structure of it, and found it equally ingenious with that of the external. There are many entrances, each of which forms a regular street, with nests on both sides, at about two inches distant from each other.

9. The tridactyla, or three-toed grossbeak, (the guifso balito of Buffon) has only three toes, two before and one behind. The bill is toothed on the edges; the head, throat, and fore-part of the neck, are of a beautiful red; the upper part of the neck, back, and tail, are black; the wing-coverts brown, edged with white; quills brown, with greenish edges; and legs a dull red; the wings reach half-way on the tail. This species inhabits Abyssinia, where it frequents woods, and is a solitary species.

According to Linnæus there are 48 species of the loxia.

LOZENGE, Lozange, *rhombus*, in geometry, a quadrilateral figure, consisting of four equal and parallel sides, two of whose opposite angles are acute, and the other two obtuse; the distance between the two obtuse ones being always equal to the length of one side: when the sides are unequal, this figure is called a rhomboides.

Lozenge, in heraldry, a rhombus, or figure of equal sides, but unequal angles.

Lozenge, in pharmacy, the same with what is otherwise called troche.

LUCANUS, *stag chaffer*, a genus of insects of the order coleoptera: the generic character is, antennæ clavated, with compressed tip, divided into lamellæ on the inner side; jaws stretched forwards, exserted, and toothed. The principal species is the lucanus cervus, commonly known by the name of the stag-beetle, or stag-chaffer. It is the largest of all the European coleopterous insects, sometimes measuring nearly two inches and a half in length, from the tips of the jaws to the end of the body. Its general colour is a deep chesnut, with the thorax and head, which is of a squarish form, of a blacker cast; and the jaws are often of a brighter or redder chesnut-colour than the wing-shells; the legs and under-parts are coal-black, and the wings, which, except during flight, are concealed under the shells, are large, and of a fine pale yellowish-brown. This remarkable insect is chiefly found in the neighbourhood of oak-trees, delighting in the sweet exsudation or honey-dew so frequently observed on the leaves. Its larva, which perfectly resembles that of the genuine beetles, is also found in the hollows of oak-trees, residing in the fine vegetable mould usually seen in such cavities, and feeding on the softer parts of the decayed wood. It is of very considerable size, of a pale-yellowish or whitish-brown colour; and when stretched out at full length, measures nearly four inches. When arrived at its full size, which, according to some, is hardly sooner than the fifth or sixth year, it forms, by frequently turning itself, and moistening it with its glutinous saliva, a smooth oval hollow in the earth, in which it lies, and afterwards remaining perfectly still for the space of near a month, divests itself of its skin, and commences pupa or chrysalis. It is now of a shorter form than before, of a rather deeper colour, and exhibits in a striking manner the rudiments of the large extended jaws and broad head so conspicuous in the perfect insect: the legs are also proportionally larger and longer than in the larva state. The ball of earth in which this chrysalis is contained is considerably larger than a hen's egg, and of a rough exterior surface, but perfectly smooth and polished within. The chrysalis lies about three months before it gives birth to the complete insect, which usually emerges in the months of July and August. The time, however, of this insect's growth and appearance in all its states varies much, according to the difference of seasons. It is not very uncommon in many parts of England.

The commonly supposed female differs so much in appearance from the male, that it has by some authors been considered as a distinct species. It is not only smaller than the former, but totally destitute of the long and large ramified jaws, instead of which it has a pair of very short curved ones, slightly denticulated on their inner side: the head is also of considerably smaller diameter than the thorax. In point of colour it resembles the former.

The exotic species of this genus are mostly natives of America, and one in particular, frequently found in Virginia, is so nearly allied to the English stag-beetle as hardly to differ, except in having fewer denticulations or divisions on the jaws.

A highly elegant species has lately been discovered in New Holland. This differs from the rest in being entirely of a beautiful golden-green colour, with short, sharp-pointed, denticulated jaws of a brilliant copper-colour. The whole length of the insect is rather more than an inch. There are seven species of the lucanus.

LUCIDA, in astronomy, an appellation given to several fixed stars on account of their superior brightness; as the lucida coronæ, a star of the second magnitude in the northern crown; the lucida hydræ, or cor hydræ; and the lucida lyræ, a star of the first magnitude in that constellation.

LUDWIGIA, a genus of the monogynia order, in the tetrandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. The corolla is tetrapetalous; the calyx quadripartite, superior; the capsule tetragonal, quadrilocular, inferior, and polyspermous. There are four species, annuals of the West Indies.

LUES. See MEDICINE.

LUMBAGO. See MEDICINE.

LUMBRICUS, the *worm*, in zoology; a genus of insects belonging to the order of vermes intestina. The body is cylindrical, annulated, with an elevated belt near the middle, and a vent-hole on its side. There are two species of this animal: 1. Lumbricus terrestris, the earth or dew worm, Mr. Barbut observes, differs extremely in colour and external appearance in the different periods of its growth, which has occasioned people little acquainted with the variations of this kind of animals to make four or five different species of them. The general colour is a dusky red. They live under ground, never quitting the earth but after heavy rains, or at the approach of storms. The method to force them out is, either to water the ground with infusions of bitter plants, or to trample on it. The bare motion on the surface of the soil drives them up, in fear of being surprised by their formidable enemy, the mole. The winding progression of the worm is facilitated by the inequalities of its body, armed with small, stiff, sharp-pointed bristles: when it means to insinuate itself into the earth, there oozes from its body a clammy liquor, by means of which it slides down. It never damages the roots of vegetables. Its food is a small portion of earth, which it has the faculty of digesting. The superfluity is ejected by way of excrement, under a vermicular appearance. Earth-worms are hermaphrodites. 2. The marinus, marine worm, or lug, (see Plate Nat. Hist. fig. 255.) is of a pale red colour, and the body is composed of a number of annular joints; the skin is scabrous, and all the rings or joints are covered with little prominences, which render it extremely rough to the touch. It is an inhabitant of the mud about the sea-shores, and serves for food to many kinds of fish. The fishermen bait their hooks and nets with it.

LUNAR CAUSTIC. } See SILVER, CHEMISTRY, and SALTS, *Detonating*.
LUNA CORNEA. }

LUNARIA, SATIN-FLOWER, MOONWORT, or HONESTY, a genus of the siliculosa order, in the tetradynamia class of plants, and in the natural method ranking under the 39th order, siliquosæ. The silicula is entire, elliptical, compressed-plane, and pedicellated; with the valves equal to the partition, parallel, and plane; the leaves of the calyx are alternately fritted at the base. There are three species. This plant is famous in some parts of the kingdom for its medicinal virtues, though it has not the fortune to be received in the shops. The people in the northern countries dry the whole plant in an oven, and give as much as will lie on a shilling for a dose twice a day in hemorrhages of all kinds, and with great success. The Welsh, among whom it is not uncommon, Dr. Needham informs us, make an ointment of it, which they use externally, and pretend it cures dysenteries.

LUNATIC. See IDIOT.

LUNGS. See ANATOMY, and PHYSIOLOGY.

LUPINUS, *lupin*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The calyx is bilabiated; there are five oblong and five roundish antheræ; the legumen is coriaceous. There are ten species, chiefly hardy herbaceous flowery annuals, rising with upright stalks from one to three or four feet high, ornamented with digitate or fingered leaves, and terminated by long whorled spikes of papilionaceous flowers, white, blue, yellow, and rose-coloured. They are all easily raised from seed, and succeed in any open borders, where they make a fine variety.

LUPUS, in astronomy, a southern constellation, consisting of 19, or, according to Flamsteed, of 24 stars.

LUSTRATION, in antiquity, sacrifices or ceremonies by which the antients purified their cities, fields, armies, or people, defiled by any crime or impurity.

LUSTRE, a term signifying the gloss or brightness which appears on the external surface of a mineral, or on the internal surface when newly broken. The first is called the external, the second internal lustre. Two particulars respecting lustre require attention, viz. the degree, and the kind.

1. With respect to degree, Dr. Thomson gives five terms of comparison, viz. 1. very brilliant; 2. brilliant; 3. sub-brilliant; 4. glimmering, that is, having only certain parts brilliant; 5. dull, or without lustre.

2. With respect to kind, the lustre is either metallic or common. The common lustre is subdivided into vitreous or glossy, silky, waxy or greasy, mother of pearl, diamond, and semi-metallic.

LUTE, a stringed instrument formerly much in use; antiently containing only five rows of strings, but to which six, or more, were afterwards added. The lute consists of four parts, viz. the table; the body, which has nine or ten sides; the neck, which has as many stops or divisions; and the head, or cross, in which screws for tuning it are inserted. In playing this instrument, the performer strikes the strings with the fingers of the right hand, and regulates the sounds with those of the left hand. The origin of this instrument is not known, though generally believed to be of very early date. Indeed, authors are not agreed as to the country to which we are indebted for its invention. Some give it to Germany, and derive its name from the German word laute, which signifies the same thing, while others ascribe it to the Arabians, and trace its name from the Arabic alland.

LUTES. In many chemical operations the vessels must be covered with something to preserve them from the violence of the fire, from being broken or melted; and also to close exactly their joinings to each other, in order to retain the substances which they contain, when they are volatile, and reduced to vapour.

The coating used for retorts, &c. to defend them from the action of the fire, is usually composed of nearly equal parts of coarse sand, and refractory clay. These matters ought to be well mixed with water and a little hair, so as to form a liquid paste, with which the vessels are covered, layer upon layer, till it is of the required thickness. The sand mixed with the clay is necessary to prevent the cracks which are occasioned by the contracting of the clay during its drying, which it always does when pure. The hair serves also to bind the parts of the lute, and to keep it applied to the vessel; for, notwithstanding the sand which is introduced into it, some cracks are always formed, which would occasion pieces of it to fall off.

The lutes with which the joinings of vessels are closed, are of different kinds, according to the nature of the intended operations, and of the substances to be distilled in these vessels.

When vapours of watery liquors, and such as are not corrosive, are to be contained, it is sufficient to surround the joining of the receiver, to the nose of the alembic, or of the retort, with slips of paper or linen, covered with flour paste. In such cases also, slips of wet bladder are very conveniently used.

When more penetrating and dissolving vapours are to be contained, a lute is to be employed of quick-lime, slacked in air, and beaten into a liquid paste with whites of eggs. This paste is to be spread upon linen slips, which are to be applied exactly to the joining of the vessel. This lute is very convenient, easily dries, becomes solid, and sufficiently firm.

Lastly, when saline, acid, and corrosive vapours are to be contained, we must then have recourse to the lute called fat-lute. This lute is made by forming into a paste some dried clay finely powdered, sifted through a silken searce, and moistened with water; and then, by beating this paste well in a mortar with boiled linseed-oil, that is, oil which has been rendered dry by litharge dissolved in it, this lute easily takes and retains the form given to it. It is generally rolled into cylinders of a convenient size. These are to be applied, by flattening them, to the joinings of the vessels, which ought to be perfectly dry; because the least moisture would prevent the lute from adhering. When the joinings are closed with this fat-lute, the whole is to be covered with slips of linen spread with a lute of lime and whites of eggs. These slips are to be fastened with packthread. The second lute is necessary to keep on the fat-lute, because the latter remains soft, and does not become solid enough to stick on alone.

Ground linseed made into a paste with water makes also a very useful lute for most occasions.

LUTHERANS, the christians who follow the opinions of Martin Luther, one of the principal reformers of the church in the sixteenth century. See Gregory's Church History, vol. ii.

LUXATION. See SURGERY.

LYCHNIS, *campion*, a genus of the pentagynia order, in the pentandria class of plants, and in the natural method ranking under the 22d order, caryophylleæ. The calyx is monophyllous, oblong, and smooth; there are five unguiculated petals, with the segments of the limbs almost bifid; the capsule quinquelocular. There are 12 species, the principal are, 1. The chalcedonica, or chalcedonian scarlet. Of this there are varieties, with single scarlet flowers, with large double scarlet flowers of exceeding beauty and elegance, with pale red flowers, and with white flowers. Of these varieties the double scarlet lychnis is superior to all for size and elegance, the flowers being large, very double, and collected into a very large bunch, exhibit a charming appearance; the single scarlet kind is also very pretty, and the others effect an agreeable variety with the scarlet kinds. 2. The diurna: the varieties are, the common single red-flowered bachelor's button, double red, double white, and single white-flowered. The double varieties are exceedingly ornamental in their bloom; the flowers large, very double, and continue long in blow; the single red sort grows wild by ditch-sides and other moist places in many parts of England; from which the doubles were accidentally obtained by culture in gardens. 3. The viscaria, or viscous German lychnis, commonly called catch-fly. Of this also there are varieties with single red flowers, with double red flowers, and with white flowers. The double variety is considerably the most eligible for general culture, and is propagated in plenty by parting the roots. All the varieties of this species emitting a glutinous liquid matter from their stalks, flies happening to light on them sometimes stick and entangle themselves, whence the plant obtains the name catch-fly. 4. The flos cuculi, cuckoo-flower lychnis. The flowers having each petal deeply quadrifid in a torn or ragged-like manner, the plant obtained the name of ragged robin. There are varieties with single and double flowers. The double sort is a large flower; it is an improved variety of the single, which grows wild in most of our moist meadows, and is rarely cultivated; but the double, being very ornamental, merits culture in every garden.

LYCIUM, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 28th order, luridæ. The corolla is tubular, having its throat closed up with the beard of the filaments; the berry is bilocular. There are eight species, natives of various countries, and chiefly shrubs.

LYCOPERDON, a genus of the natural order of fungi, belonging to the cryptogamia class of plants. The fungus is roundish, and full of farinaceous seeds. Dr. Withering reckons 25 species, of which the following are the most remarkable: 1. The tuber, truffles, or subterraneous puff-balls, is a native of woods both in England and Scotland. It is a subterraneous fungus, growing generally in clusters 3 or 4 inches under ground, without any visible root. The figure of it is nearly spherical, the size that of a potatoe; the exterior coat at first white, afterwards black, and studded with pyramidical or polyhedrous tubercles; the internal substance solid and callous, of a dirty-white or pale-brown colour, grained like a nutmeg with serpentine lines; in which, according to Micheli, are imbedded minute oval capsules, containing each from 2 to 4 round warted seeds. The truffles of Great Britain seldom exceed 3 or 4 ounces in weight; but in Italy, and some other parts of the continent, they are said to have been found of the enormous size of 8, and even 14 pounds. They have a volatile and somewhat urinous smell, and are reputed to be aphrodisiacal. 2. The bovista, or common puff-ball, is frequent in meadows and pastures in the autumn. It varies exceedingly in size, figure, superficies, and colour. In general, it consists of a sack or bag, having a root at its base, and the bag composed of 3 membranes, an epidermis, a tough white skin, and an interior coat which adheres closely to the central pith. The pith in the young plants is of a yellowish colour, at first firm and solid, but soon changes into a cellular spongy substance, full of a dark dull-green powder, which discharges itself through an aperture at the top of the fungus, which aperture is formed of lacerated segments, in some varieties reflexed. The powder is believed to be the seeds, which through a microscope appear of a spherical form, and to be annexed to elastic hairs.

LYCOPODIUM, or CLUB-MOSS, a genus of the natural order of musci, belonging to the cryptogamia class of plants. The antheræ are bivalved and sessile; there are no calyptra. There are 29 species, of which the following are the most remarkable: 1. The clavatum, or common club-moss, is common in dry and mountainous places, and in fir forests. The stalk is prostrate, branched, and creeping from a foot to two or three yards long; the radicles woody. The leaves are numerous, narrow, lanceolated, acute, often incurved at the extremity, terminated with a long white hair, and every where surround the stalk. The peduncles are erect, firm, and naked, (except being thinly set with lanceolet scales), and arise from the ends of the branches. They are generally two or three inches long, and terminated with two cylindrical yellowish spikes, imbricated with oval-acute scales, finely lacerated on the edges, and ending with a hair. In the ala or bosom of the scale is a kidney-shaped capsule, which bursts with elasticity when ripe, and throws out a light-yellow powder, which, blown into the flame of a candle, flashes with an explosion.

LYCOPSIS, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 41st order, asperifoliæ. The corolla has an incurvated tube. There are eight species, chiefly annuals.

LYCOPUS, a genus of the monogynia order, belonging to the diandria class of plants, and in the natural method ranking under the 42d order, verticillatæ. The corolla is quadrifid, with one of the segments emarginated; the stamina standing asunder, with four retuse seeds. There are three species, of which the water-horehound might probably be of use in dyeing.

LYGEUM, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the fourth order, gramina. The spatha or sheath is monophyllous; there are a pair of corollæ upon the same germen; the nut is bilocular. There is one species, a grass of Spain.

LYDIAN STONE, in mineralogy, is commonly intersected by veins of quartz. Fracture even, and sometimes inclining to conchoidal. Specific gravity 2.6 nearly. Powder black, or greyish black. This stone, or one similar to it, was used by the antients as a touchstone. They drew the metal to be examined along the stone, and judged of its purity by the colour of the metallic streak. On this account it was called Βασανος, the trier. It was called the Lydian stone, as being found in the river Tmolus in Lydia.

LYMPH. See ANATOMY, and PHYSIOLOGY.

LYNX. See FELIS.

LYRE, LYRA, a musical instrument of the string kind, much used by the antients.

LYRE, *lyra*, in astronomy, a constellation of the northern hemisphere, the number of whose stars, in Ptolomy's and Tycho's catalogues, are only 10, but 19 in the Britannic catalogue.

LYRIC. See POETRY.

LYSIMACHIA, *loosestrife*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 20th order, rotaceæ. The corolla is rotaceous; the capsule globular, beaked, and ten-valved. There are 12 species, but only four are commonly cultivated in gardens. These are hardy herbaceous perennials and biennials, rising with erect stalks from 18 inches to two or three feet high, and terminated by spikes and clusters of monopetalous, rotated, five-parted spreading flowers of white and yellow colours. The nummulana, or yellow moneywort, or herb jevoperee, is particularly beautiful.

LYTHRUM, *purple loosestrife*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. The calyx is cleft in 12 parts; and there are six petals inserted into it; the capsule is bilocular and polyspermous. There are 18 species, of which the most remarkable are, 1. The salicaria, or common purple loosestrife, with oblong leaves, is a native of Britain, and grows naturally by the sides of ditches and rivers. 2. The hispanum, or Spanish loosestrife, with a hyssop leaf, grows naturally in Spain and Portugal. The flowers are larger than those of the common sort, and make a fine appearance in the month of July, when they are in beauty.

M.

M, the twelfth letter of our alphabet. As a numeral it stands for mille, a thousand; and with a dash over it, thus $\overline{M}$, for a thousand times a thousand, or 1000000. Used as an abbreviature M. signifies Manlius, Marcus, Martius, Mucius; and M. Manius; M. B. mulier bona; Mag. Eq. magister equitum; Mag. Mil. magister militum; M. M. P. manu mancipio potestate; M. A. magister artium; MS. manuscript, and M.SS. manuscripts, in the plural. In the prescriptions of physicians, M. stands for manipulus, a handful; and sometimes for misce, or mixtura.

MABA, a genus of the triandria order, in the diœcia class of plants. The perianthium of the male is trifid; that of the female is as in the male; the fruit is a plum two-celled, superior. There is one species, a tree of the Friendly islands.

MABEA, a genus of the monoecia polyandria class and order. The calyx is one-leaved; corolla none. There are two species, called pipewood, shrubs of the West Indies.

MACARONIC, or MACARONIAN, an appellation given to a burlesque kind of poetry, made up of a jumble of words of different languages, and words of the vulgar tongue latinized.

MACE, the second coat or covering of the kernel of the nutmeg, is a thin and membranaceous substance, of an oleaginous nature and a yellowish colour; being met with in flakes of an inch and more in length, which are divided into a multitude of ramifications. It is of an extremely fragrant, aromatic, and agreeable flavour, and of a pleasant, but acrid and oleaginous taste. See MYRISTICA.

MACERATION, in pharmacy, is an infusion of, or soaking ingredients in, water, or any other fluid, in order either to soften them or draw out their virtues.

MACHINE. See MECHANICS.

MACKREL. See SCOMBER.

MACROCNEMON, a genus of the class and order pentandria monogynia. The cor. is bell-shaped; the capsule two-celled, two-valved; seeds imbricate. There are three species, small trees of the West Indies.

MACROLOBIUM, a genus of the class and order triandria monogynia. The calyx is double, pet. five, germ. pedicelled legume. There are three species, trees of Guiana.

MACULÆ, in astronomy, are dark spots appearing on the luminous surfaces of the sun and moon, and even some of the planets. The solar maculæ are dark spots of an irregular and changeable figure, observed in the face of the sun. These were first observed in November and December of the year 1610, by Galileo in Italy, and Harriot in England, unknown to, and independant of, each other, soon after they had made or procured telescopes.

There have been various observations made of the phenomena of the solar maculæ, and hypotheses invented for explaining them. Many of these maculæ appear to consist of heterogeneous parts; the darker and denser being called, by Hevelius, nuclei, which are encompassed as it were with atmospheres, somewhat rarer and less obscure; but the figure, both of the nuclei and entire maculæ, is variable. These maculæ are often subject to sudden mutations. In 1644 Hevelius observed a small thin macula, which in two days time grew to ten times its bulk, appearing also much darker, and having a larger nucleus: the nucleus began to fail sensibly before the spot disappeared; and before it quite vanished, it broke into four, which reunited again two days after. Some maculæ have lasted 2, 3, 10, 15, 20, 30, but seldom 40 days; though Kirchius observed one in 1681, that was visible from April 26th to the 17th of July. It is found that the spots move over the sun's disc with a motion somewhat slacker near the edge than in the middle parts; that they contract themselves near the limb, and in the middle appear larger; that they often run into one in the disc, though separated near the centre; that many of them first appear in the middle, and many disappear there; but that none of them deviate from their path near the horizon; whereas Hevelius, observing Mercury in the sun near the horizon, found him too low, being depressed 27″ beneath his former path.

From these phenomena are collected the following consequences:

1. That since Mercury's depression below his path arises from his parallax, the maculæ, having no parallax from the sun, are much nearer him than that planet.

2. That since they rise and disappear again in the middle of the sun's disc, and undergo various alterations with regard both to bulk, figure, and density, they must be formed de novo, and again dissolved about the sun; and hence some have inferred, that they are a kind of solar clouds, formed out of his exhalations; and if so, the sun must have an atmosphere.

3. Since the spots appear to move very regularly about the sun, it is hence inferred, that it is not that they really move, but that the sun revolves round his axis, and the spots accompany him, in the space of 27 days, 12 hours, 20 minutes.

4. Since the sun appears with a circular disc in every situation, his figure, as to sense, must be spherical.

The magnitude of the surface of a spot may be estimated by the time of its transit over a hair in a fixed telescope. Galileo estimates some spots as larger than both Asia and Africa put together; but if he had known more exactly the sun's parallax and distance, as they are known now, he would have found some of those spots much larger than the whole surface of the earth. For in 1612 he observed a spot so large as to be plainly visible to the naked eye, and therefore it subtended an angle of about a minute. But the earth, seen at the distance of the sun, would subtend an angle of only about 17″; therefore the diameter of the spot was to the diameter of the earth, as 60 to 17, or $3\frac{1}{2}$ to 1 nearly; and consequently the surface of the spot, if circular, to a great circle of the earth, as $12\frac{1}{4}$ to 1, and to the whole surface of the earth, as $12\frac{1}{4}$ to 4, or nearly 3 to 1. Gassendus observed a spot whose breadth was $\frac{1}{20}$ of the sun's diameter, and which therefore subtended an angle at the eye of above a minute and a half, and consequently its surface was above seven times larger than the surface of the whole earth. He says he observed above 40 spots at once, though without sensibly diminishing the light of the sun.

In the year 1779 there was a spot on the sun which was large enough to be seen by the naked eye. It was divided into two parts, and must have been 50,000 miles in diameter.

Various opinions have been formed concerning the nature, origin, and situation of the solar spots; but the most probable seems to be that of Dr. Wilson, professor of practical astronomy in the university of Glasgow. By attending particularly to the different phases presented by the umbra, or shady zone, of a spot of an extraordinary size that appeared on the sun, in the month of November 1769, during its progress over the solar disc, Dr. Wilson was led to form a new and singular conjecture on the nature of these appearances; which he afterwards greatly strengthened by repeated observations. The results of these observations are, that the solar maculæ are cavities in the body of the sun; that the nucleus, as the middle or dark part has usually been called, is the bottom of the excavations; and that the umbra, or shady zone surrounding it, is the shelving sides of the cavity. Dr. Wilson, besides having satisfactorily ascertained the reality of these immense excavations in the body of the sun, has also pointed out a method of measuring the depth of them. He estimates, in particular, that the nucleus or bottom of the large spot above-mentioned, was not less than a semidiameter of the earth, or about 4000 miles below the level of the sun's surface; while its other dimensions were of a much larger extent. He observed that a spot near the middle of the sun's disc is surrounded equally on all sides with its umbra; but that when, by its apparent motion over the sun's disc, it comes near the western limb, that part of the umbra which is next the sun's centre gradually diminishes in breadth, till near the edge of the limb it totally disappears; whilst the umbra on the other side of it is little or nothing altered. After a semi-revolution of the sun on his axis, if the spot appear again, it will be on the opposite side of the disc, or on the left hand, and the part of the umbra which had before disappeared is now plainly to be seen; while the umbra on the other side of the spot seems to have vanished in its turn, being hid from the view by the upper edge of the excavation, from the oblique position of its sloping sides with respect to the eve. But as the spot advances on the sun's disc, this umbra, or side of the cavity, comes in sight; at first appearing narrow, but afterwards gradually increasing in breadth, as the spot moves towards the middle of the disc. These appearances perfectly agree with the phases that are exhibited by an excavation in a spherical body, revolving on its axis; the bottom of the cavity being painted black, and the sides lightly shaded.

Dr. Herschel supposes that the spots in the sun are mountains on its surface, which considering the great attraction exerted by the sun upon bodies placed at its surface, and the slow revolution it has about its axis, he thinks may be more than 300 miles high. He says, that in August 1792 he examined the sun with several powers, from 90 to 500; and it appeared that the black spots are the opaque ground or body of the sun, and that the luminous part is an atmosphere which being broken, gives a glimpse of the sun itself.

MADDER. See Rubia.

MADNESS. See Medicine.

MADREPORA, in natural history, the name of a genus of submarine substances, the characters of which are, that they are almost of a stony hardness, resembling the corals, and are usually divided into branches, and pervious by many holes or cavities, which are frequently of a stellar figure.

In the Linnæan system, this is a genus of lithophyta: the animal that inhabits it is a medusa; it comprehends 39 species. According to Donati, the madrepora is like the coral as to its hardness, which is equal to bone or marble; the colour is white when polished; its surface is lightly wrinkled, and the wrinkles run lengthwise of the branches; in the centre there is a sort of cylinder, which is often pierced through its whole length by two or three holes. From this cylinder are detached about 17 laminæ, which run to the circumference in straight lines; and are transversely intersected by other laminæ, forming many irregular cavities; the cellules, which are composed of these laminæ ranged into a circle, are the habitations of little polypes, which are extremely tender animals, generally transparent, and variegated with beautiful colours. M. de Peyssonel observes, that those writers who only considered the figures of submarine substances, denominated that class of them which seemed pierced with holes, pora; and those the holes of which were large they called madrepora. He defines them to be all those marine bodies which are of a stony substance, without either bark or crust, and which have but one apparent opening at each extremity, furnished with rays that proceed from the centre to the circumference. He observes that the body of the animal of the madrepora, whose flesh is so soft that it divides upon the gentlest touch, fills the centre; the head is placed in the middle, and surrounded by several feet or claws, which fill the intervals of the partitions observed in this substance, and are at pleasure brought to its head, and are furnished with yellow papillæ. He discovered that its head or centre was lifted up occasionally above the surface, and often contracted and dilated itself like the pupil of the eye: he saw all its claws moved, as well as its head or centre. When the animals of the madrepora are destroyed, its extremities become white. In the madrepora, he says, the animal occupies the extremity, and the substance is of a stony but more loose texture than the coral. This is formed, like other substances of the same nature, of a liquor which the animal discharges: and he farther adds, that there are some species of the polype of the madrepora which are produced singly, and others in clusters. See Plate Nat. Hist. figs. 256 and 257; and Zoophytes.

MADREPORITE, a mineral found in the valley of Russback in Salzburg, and which obtained its name from its resemblance to madrepore. Colour in some parts black, in others dark-grey. Found in large round masses. Fracture even passing to the conchoidal. Lustre greasy, passing to the silky. Brittle: moderately heavy. Streak grey; it is composed of 93.00 carbonat of lime

0.50 carbonat of magnesia
7.25 carbonat of iron
0.50 charcoal
4.50 silica in sand.

99.75

MADRIER, in the military art, a long and broad plank of wood, used for supporting the earth in mining and carrying on a sap, and in making coffers, caponiers, galleries, and for many other uses at a siege. Madriers are also used to cover the mouths of petards after they are loaded, and are fixed with the petards to the gates or other places designed to be forced open.

MÆMACTERION, the fourth month of the Athenian year, consisting of only 29 days, and answering to the latter part of September and the beginning of October.

MAGAZINE, a place in which stores are kept, or arms, ammunition, provisions, &c. Every fortified town ought to be furnished with a large magazine, which should contain stores of all kinds, sufficient to enable the garrison and inhabitants to hold out a long siege, and in which smiths, carpenters, wheelwrights, bakers, &c. may be employed in making every thing belonging to the artillery, as carriages, waggons, &c.

Magazine, *powder*, is that place where the powder is kept in very large quantities. Authors differ greatly both in regard to situation and construction; but all agree, that they ought to be arched, and bomb-proof. In fortifications they are frequently placed in the rampart; but of late they have been built in different parts of the town. The first powder-magazines were made with Gothic arches; but M. Vauban, finding them too weak, constructed them in a semicircular form, whose dimensions are 60 feet long within, 25 broad; the foundations are eight or nine feet thick, and eight feet high from the foundation to the spring of the arch; the floor is two feet from the ground, which keeps it from dampness.

One of our engineers of great experience, some time since, had observed, that after the centres of semicircular arches are struck, they settle at the crown, and rise up at the haunches, even with a straight horizontal extrados; and still much more so in powder-magazines, whose outside at top is formed like the roof of a house, by two inclined planes joining in an angle over the top of the arch, to give a proper descent to the rain; which effects are exactly what might be expected agreeable to the true theory of arches. Now, as this shrinking of the arches must be attended with very ill consequences, by breaking the texture of the cement after it has been in some degree dried, and also by opening the joints of the voussoirs at one end, so a remedy is provided for this inconvenience, with regard to bridges, by the arch of equilibration in Dr. Hutton's book on bridges; but as the ill effect is much greater in powder-magazines, the same ingenious gentleman proposed to find an arch of equilibration for them also, and to construct it when the span is 20 feet, the pitch or height 10 (which are the same dimensions as the semicircle), the inclined exterior walls at top forming an angle of 113 degrees, and the height of their angular point above the top of the arch equal to seven feet.

MAGI, or Magians, an antient religious sect in Persia, and other Eastern countries, who maintained, that there were two principles, the one the cause of all good, the other the cause of all evil; and abominating the adoration of images, worshipped God only by fire, which they looked upon as the brightest and most glorious symbol of Oromasdes, or the good God: as darkness is the truest symbol of Arimanius, or the evil God. This religion was reformed by Zoroaster. The sect still subsists in Persia, under the denomination of gaurs.

MAGIC Lantern. See Optics.

Magic Square, in arithmetic, a square figure made up of numbers in arithmetical proportion, so disposed in parallel and equal ranks, that the sums of each row, taken either perpendicularly, horizontally, or diagonally, are equal: thus,

Natural square.

9	5	1
4	3	8

Magic squares seem to have been so called, from their being used in the construction of talismans.

MAGNA CHARTA, the great charter of the liberties of England, and the basis of our laws and privileges.

This charter may be said to derive its origin from king Edward the Confessor, who granted several privileges to the church and state, by charter; these liberties and privileges were also granted and confirmed by king Henry I., by a celebrated great charter now lost; but which was confirmed or re-enacted by king Henry II. and king John. Henry III., the successor of this last prince, after having caused twelve men to make enquiry into the liberties of England in the reign of Henry I., granted a new charter, which was the same as the present Magna Charta; this he several times confirmed, and as often broke; till in the thirty-seventh year of his reign, he went to Westminster-hall, and there in the presence of the nobility and bishops, who held lighted candles in their hands, Magna Charta was read, the king all the while holding his hand to his breast, and at last solemnly swearing faithfully and inviolably to observe all the things therein contained, &c.; then the bishops extinguishing the candles, and throwing them on the ground, cried out, "Thus let him be extinguished, and stink in hell, who violates this charter." It is observed, that notwithstanding the solemnity of this confirmation, king Henry, the very next year, again invaded the rights of his people, till the barons entered into a war against him; when, after various success, he confirmed this charter, and the charter of the forest, in the fifty-second year of his reign. This excellent charter, so equitable and beneficial to the subject, is the most antient written law in the kingdom: by the 25 Edw. I. it is ordained, that it shall be taken as the common law; and by the 43 Edw. III. all statutes made against it are declared to be void.

MAGNESIA. About the beginning of the eighteenth century, a Roman canon exposed a white powder to sale at Rome as a cure for all diseases. This powder he called magnesia alba. He kept the manner of preparing it a profound secret; but in 1707 Valentini informed the public that it might be obtained by calcining the lixivium which remains after the preparation of nitre; and two years after, Slevogt discovered that it might be precipitated by potass from the mother-ley of nitre. This powder was generally supposed to be lime, till Frederic Hoffman observed that it formed very different combinations with other bodies. But little was known concerning its nature, and it was even confounded with lime by most chemists, till Dr. Black made his celebrated experiments on it in 1755. Margraff published a dissertation on it in 1759, and Bergman another in 1775, in which he collected the observations of these two philosophers, and which he enriched also with many additions of his own. Butini of Geneva likewise published a valuable dissertation on it in 1779.

As magnesia has never yet been found native in a state of purity, it may be prepared in the following manner: sulphat of magnesia, a salt composed of this earth and sulphuric acid, exists in sea-water, and in many springs, particularly in some about Epsom; from which circumstance it was formerly called Epsom salt. This salt is to be dissolved in water, and half its weight of potass added. The magnesia is immediately precipitated, because potass has a stronger affinity for sulphuric acid. It is then to be washed with a sufficient quantity of water, and dried.

Magnesia thus obtained is a very soft white powder, which has very little taste, and is totally destitute of smell. Its specific gravity is about 2.3. It converts delicate vegetable blues (paper for instance, stained with the petals of the mallow) to green.

It is not melted by the strongest heat which it has been possible to apply; but M. Darcet observed that, in a very high temperature, it became somewhat agglutinated. When formed into a cake with water, and then exposed to a violent heat, the water is gradually driven off, and the magnesia contracts in its dimension; at the same time, it acquires the property of shining in the dark when rubbed upon a hot iron plate.

It is almost insoluble in water; for, according to Mr. Kirwan, it requires 7900 times its weight of water at the temperature of 60° to dissolve it. It is capable, however, of combining with water in a solid state; for 100 parts of magnesia, thrown into water, and then dried, are increased in weight to 118 parts. Even when combined with carbonic acid (for which it has a strong affinity) it is capable of absorbing and retaining $1\frac{1}{2}$ times its own weight of water without letting go a drop; but on exposure to the air, this water evaporates, though more slowly than it would from lime.

Magnesia has never yet been obtained in a crystallized form.

When exposed to the air, it attracts carbonic acid gas and water; but exceedingly slowly. Butini left a quantity of it for two years in a porcelain cup merely covered with paper; its weight was only increased $\frac{1}{144}$ part.

Magnesia does not combine with oxygen; nor is it altered by any of the compounds into which oxygen enters. The only one of the simple combustibles with which it can be united is sulphur. No person has hitherto succeeded in forming a phosphuret of magnesia. The sulphuret of magnesia may be formed by exposing a mixture of two parts of magnesia and one part of sulphur, to a gentle heat in a crucible. The result is a yellow powder, slightly agglutinated, which emits very little sulphureted hydrogen gas, when thrown into water. A moderate heat is sufficient to drive off the sulphur.

Magnesia does not combine with azote, but it unites with muriatic acid, and forms a compound called muriat of magnesia. It has no action upon the metals: nor does it combine, as far as is known at present, with the metallic oxides, unless some intermediate substance is present. It does not combine with the fixed alkalies, neither are its properties altered by these bodies; but it has a strong propensity to enter into triple compounds with ammonia.

There seems to be little affinity between magnesia and barytes; at least no mixture of the two earths is fusible in the strongest heat which it has been possible to apply.

Mr. Kirwan has shown that there is but little affinity between strontian and magnesia. They do not melt when exposed to a strong heat, at least when the strontian exceeds or equals the magnesia.

Equal parts of lime and magnesia, mixed together, and exposed by Lavoisier to a very violent heat, did not melt; neither did they melt when Mr. Kirwan placed them in the temperature of 150° Wedgewood.

The affinities of magnesia, according to Bergman, are as follows:

Oxalic acid,	Tartaric,
Phosphoric,	Citric,
Sulphuric,	Lactic,
Fluoric,	Benzoic,
Arsenic,	Acetic,
Saclactic,	Boracic,
Succinic,	Sulphurous,
Nitric,	Carbonic,
Muriatic,	Prussic.

Magnesia is used in medicine, to remove acidities.

MAGNETISM. The natural magnet, or loadstone, is a hard mineral body of a dark brown, or almost black colour, and when examined, is found to be an ore of iron. It is met with in various countries, generally in iron mines, and of all sizes and forms.

This singular substance was known to the antients; and they had remarked its peculiar property of attracting iron, though it does not appear that they were acquainted with the wonderful property which it also has, of turning to the pole when suspended, and left at liberty to move freely.

Upon this remarkable circumstance the mariner's compass depends, an instrument which gives us such infinite advantages over the antients. It is this which enables the mariners to conduct their vessels through vast oceans out of the sight of land, in any given direction; and this directive property also guides the miners in their subterranean excavations, and the traveller through deserts otherwise impassable.

It is not precisely known when and by whom this directive property of the magnet was discovered. The most probable accounts seem to prove, that it was known early in the 13th century; and that the person who first made mariner's compasses, at least in Europe, was a Neapolitan of the name of Flavio, or John de Gioga, or Giova, or Gira.

The natural loadstone has also the quality of communicating its properties to iron and steel; and when pieces of steel properly prepared are touched, as it is called, by the loadstone, they are denominated artificial magnets.

These artificial magnets are even capable of being made more powerful than the natural ones; and as they can be made of any form, and are more convenient, they are now universally used, so that the loadstone or natural magnet is only kept as a curiosity.

All magnets, whether natural or artificial, are distinguished from other bodies by the following characteristics, which appear to be inseparable from their nature; so that no body can be called a magnet, unless it is possessed of all these properties:

1. A magnet attracts iron.

2. When a magnet is placed so as to be at liberty to move freely in every direction, its ends point towards the poles of the earth, or very nearly so; and each end always points to the same pole. This is called the polarity of the magnet; the ends of the magnet are called poles; and they are called north and south poles of the magnet, according as they point to the north or south pole of the earth. When a magnet places itself in this direction, it is said to traverse.

3. When the north pole of one magnet is presented to the south of another magnet, these ends attract each other; but if the south pole of one magnet is presented to the south pole of another, or the north pole of one to the north pole of another, these ends will repel each other.

From these criteria, it is easy to determine the names of the poles of a magnetical bar, by applying it near a suspended magnet whose poles are known.

4. When a magnet is situated so as to be at liberty to move itself with sufficient freedom, its two poles do not lie in a horizontal direction, but it generally inclines one of them towards the horizon, and of course it elevates the other pole above it. This is

called the inclination or dipping of the magnet.

5. Any magnets may, by proper methods, be made to impart those properties to iron or steel.

A plane perpendicular to the horizon, and passing through the poles of a magnet when standing in their natural direction, is called the magnetic meridian; and the angle which the magnetic meridian makes with the meridian of the plane where the magnet stands, is called the declination of the magnet at that place.

Of magnetic attraction and repulsion.—When a piece of iron is brought within a certain distance of one of the poles of a magnet, it is attracted by it; and if the iron is at liberty to move, it adheres to the magnet, and cannot be separated without some force. It appears at first sight, that the attraction lies only in the magnet, but experiment proves this attraction to be mutual; the iron attracting the magnet as much as the magnet attracts the iron. Place the magnet and the iron upon two separate pieces of cork, or wood, floating upon water, at a little distance from each other, and it will be found that the iron moves towards the magnet, as well as the magnet towards the iron; but if the iron is kept steady, the magnet will move towards it.

This attraction is strongest at the poles of a magnet, and diminishes in proportion to the distance of any part from the poles, so that in the middle between the poles there is no attraction. This may be easily perceived by presenting a piece of iron to various parts of the surface of a magnet.

The intensity of the attractive power diminishes also, according to the distance from the magnet. If the magnet and iron touch each other, it requires a certain degree of force to separate them; if the iron is removed a little way from the magnet, an attraction will be plainly perceived, but not so powerful; and by increasing this distance the attraction will be much diminished.

The law of diminution of this attraction is not yet known. Some have imagined that it diminishes in proportion to the square of the distance, others as the cube of the distance. But either from the difficulty of the subject, or on account of the experiments having been made without sufficient accuracy, the question remains yet undecided; it is only known that the attractive force decreases faster than the simple ratio of the distances.

As magnetic attraction takes place only between poles of different names of different magnets; that is, the north pole of one magnet attracts the south pole of another; consequently magnetic repulsion acts only between poles of the same name of different magnets. Thus, if the north pole of one magnet is opposed to the north pole of another magnet, or if the south pole be opposed to the south pole of the other, then those magnets will repel each other, and that nearly with as much force as the poles of different names would attract each other.

But it frequently happens, that though magnets are placed with the same poles towards each other, yet they either attract each other, or shew a perfect indifference. This, at first, seems to contradict the above-mentioned general law; but this difficulty is removed by the following considerations:

When a piece of iron is brought within a certain distance of a magnet, it becomes, in fact, itself a magnet, having the polarity, the attractive and repulsive properties for other iron, &c.; that part of it which is nearest to the south pole of the magnet, becoming a north pole, and the opposite part a south pole, or vice versa, according to the end of the magnet presented. Thus if A B, Plate Magnetism, fig. 1, be an oblong piece of iron, and be brought near the north pole N of the magnet N S, then this piece of iron while standing within the magnet's sphere of action, will have all the properties of a real magnet, and its end A will be found to be a south pole, while the end B is a north pole.

Soft iron, when placed within the influence of a magnet, easily acquires these properties; but they last only while the iron remains in that situation, and when it is removed its magnetism vanishes immediately. But with iron containing carbon, and particularly with steel, the case is very different; and the harder the iron or the steel is, the more permanent is the magnetism which it acquires from the influence of a magnet; but it will be in the same proportion more difficult to render it magnetic.

If a piece of soft iron, and a piece of hard steel, both of the same shape and size, are brought within the influence of a magnet at the same distance, it will be found that the iron is attracted more forcibly, and appears more powerfully magnetic, than the steel; but if the magnet is removed, the soft iron will instantly lose its acquired properties, whereas the hard steel will preserve them for a long time, having become an artificial magnet.

Neither the magnetic attraction nor repulsion is in the least diminished, or at all affected, by the interposition of any sort of bodies, except iron, or such bodies as contain iron.

The properties of the magnet are not affected either by the presence or by the absence of air. Heat weakens the power of a magnet, and subsequent cooling restores it, but not quite to its former degree. A white heat destroys it entirely, or very nearly so; and hence it appears, that the powers of magnets must be varying continually. Cavallo observes, that iron in a full red heat, or white heat, is not attracted by the magnet; but the attraction commences as soon as the redness begins to appear.

The attractive power of a magnet may be considerably improved by suspending a weight of iron to it by its power of attraction, which may be gradually increased; and also by keeping it in a proper situation, viz. with its north pole towards the north, and its south pole, consequently, towards the south. On the contrary, this power is diminished by an improper situation, and by keeping too small a piece of iron, or no iron at all, appended to it.

In these northern parts of the world, the north pole of a magnet has more power than its south pole; whereas, the contrary effect has been said to take place in the southern parts.

Amongst the natural magnets, the smallest generally possess a greater attractive power in proportion to their size than those of a larger size.

It frequently happens, that a natural magnet, cut off from a larger loadstone, will be able to lift a greater weight of iron than the original loadstone itself.

As both magnetic poles together attract a much greater weight than a single pole; and as the two poles of a magnet generally are in opposite parts of its surface, in which case it is almost impossible to adapt the same piece of iron to them both at the same time; therefore it has been commonly practised to adapt two broad pieces of soft iron to the poles of the stone, and to let them project on one side of the stone; for those pieces become themselves magnetic while thus situated, and to them the piece of iron or weight may be easily adapted. Those two pieces of iron are generally fastened upon the stone by means of a brass or silver box. The magnet in this case is said to be armed, and the two pieces of iron are called the armature.

Fig. 2. represents an armed magnet, where A B is the loadstone; C D, C D, are the armature, or the two pieces of soft iron, to the projections of which D D the iron weight F is to be applied. The dots E C D C D represent the brass box, with a ring at E, by which the armed magnet may be suspended.

Artificial magnets, when straight, are sometimes armed in the same manner; but they are frequently made in the shape of a horse-shoe, having their poles at the truncated extremities, as at N and S, fig. 3, in which shape it is evident that they want no armature.

Most probably the magnet attracts iron only; but when it is considered how universally iron is dispersed throughout nature, it is evident that a vast number of bodies must on that account be attracted by the magnet more or less forcibly, in proportion to the quantity and quality of the iron they contain. Indeed, it is wonderful to observe what a small portion of iron will render a body subject to the influence of the magnet.

The polarity of the magnet.—Every magnet has a south and a north pole, which are at opposite ends; and a line drawn from one end to the other, passes through the centre of the magnet. Here it must not be understood, that the polarity of a magnet resides only in two points of its surface; for in reality, it is the one half of the magnet that is possessed of one kind of polarity, and the other half of the other kind of polarity; the poles, then, are those points in which that power is the strongest.

The line drawn from one pole to the other, is called the axis of the magnet; and a line formed all round the surface of the magnet, by a plane which divides the axis into two equal parts, and is perpendicular to it, is called the equator of the magnet.

It is the polarity of the magnet that renders it so useful to navigators. When a magnet is kept suspended freely, so that it may turn north and south, the pilot, by looking at the position of it, can steer his course in any required direction. Thus, if a vessel is steered towards a certain place which lies exactly westward of that from which it set out, the navigator must direct it so, that its course may be always at right angles with the direction of the magnetic needle of his compass, keeping the north end of the magnet on the right-hand side, and of course, the south end on the left-hand side of the vessel; for as the needle points north and south, and the direction is east and west, the intended course of the vessel is exactly perpendicular to the position of the magnet. A little reflection will shew how the vessel may be steered in any other direction.

An artificial magnet fitted up in a proper box, for the purpose of guiding the direction of a traveller, is called a magnetic needle, and the whole together is called the mariner's compass.

Although the north pole of the magnet in every part of the world, when suspended, points towards the northern parts, and the south pole towards the southern parts, yet its ends seldom point exactly towards the poles of the earth. The angle in which it deviates from due north and south, is called the angle of declination, or the declination of the magnetic needle, or the variation of the compass; and this declination is said to be east or west, according as the north pole of the needle is eastward or westward of the astronomical meridian of the place.

This deviation from the meridian is not the same in all parts of the world, but is different in different places, and it is even continually varying in the same place. For instance, this declination is not the same in London as at Paris, or as in India; and the declination in London, or in any other place, is not the same at this time as it was some years ago. This declination from the meridian is so variable, that it may be observed to change, even in one or two hours time; and this is not owing to the construction of the magnetic needle; for in the same place, and at the same time, all true magnetic needles point the same way.

The declination from the meridian, and the variation of this in different parts of the world, are very uncertain, and cannot be foretold; actual trial is the only method of ascertaining them. This circumstance forms a great impediment to the improvement of navigation. It is true, that great pains have been taken by navigators and other observers, to ascertain the declination in various parts of the world, and such declinations have been marked in maps, charts, books, &c.; but still, on account of the constant change to which this variation is liable, these can only serve for a few years; nor has the law of this variation or fluctuation been yet discovered, though various hypotheses have been formed for that purpose. When the variation was first observed, the north pole of the magnetic needle declined eastward of the meridian of London; but it has since that time been changing continually towards the west; so that in the year 1657 the magnetic needle pointed due north and south. At present, it declines about 24½° westward, and it seems to be still advancing towards the west.

Before volcanic eruptions and earthquakes, the magnetic needle is often subject to very extraordinary movements.

It is also agitated before and after the appearance of the aurora borealis.

The magnetic inclination, or dip of the needle.—If a needle which is accurately balanced, and suspended so as to turn freely in a vertical plane, is rendered magnetical, the north pole will be depressed, and the south pole elevated above the horizon: this property is called the inclination, or dip of the needle, and was discovered by Robert Norman, about the year 1576.

Take a globular magnet, or, which is more easily procured, an oblong one, like S N, fig. 4; the extremity N of which is the north pole, the other extremity S is the south pole, and A is its middle or equator; place it horizontally upon a table C D: then take another small oblong magnet *n s* (viz. a bit of steel wire, or a small sewing-needle magnetized) and suspend it by means of a fine thread tied to its middle, so as to remain in an horizontal position, when not disturbed by the vicinity of iron, or other magnet. Now if the same small magnet, being held by the upper part of the thread, be brought just over the middle of the large magnet, within two or three inches of it, the former will turn its south pole *s*, towards the north pole, N, of the large magnet; and its north pole *n*, towards the south pole, S, of the large one. It will be farther observed, that the small magnet, whilst kept just over the middle A of the large one, will remain parallel to it; for since the poles of the small magnet are equally distant from the contrary poles of the large magnet, they are equally attracted. But if the small magnet be moved a little nearer to one end than to the other of the large magnet, then one of its poles, namely, that which is nearest to the contrary pole of the large magnet, will be inclined downwards, and of course the other pole will be elevated above the horizon. It is evident that this inclination must increase according as the small magnet is placed nearer to one of the poles of the large one, because the attraction of the nearest pole will have more power upon it. If the small magnet be brought just opposite to one of the poles of the large magnet, it will turn the contrary pole towards it, and will place itself in the same straight line with the axis of the large magnet.

This simple experiment will enable the reader to comprehend easily the phenomena of the magnetic inclination, or of the dipping needle, upon the surface of the earth; for it is only necessary to imagine that the earth is a large magnet (as in fact in appears to be), and that any magnet, or magnetic needle, commonly used, is the small magnet employed in the above-mentioned experiment; for, supposing that the north pole of the earth is possessed of a south magnetic polarity, and that the opposite pole is possessed of a north magnetic polarity, it appears evident, and it is confirmed by actual experience, that when a magnet, or magnetic needle, properly shaped and suspended, is kept near the equator of the earth (since neither the magnetic equator, nor the magnetic poles of the earth, coincide with its real equator and poles), it must remain in a horizontal situation: if the magnet is removed nearer to one of the magnetic poles of the earth, it must incline to one of its extremities, namely, that which is possessed of the contrary polarity; and this inclination must increase in proportion as the needle recedes from the magnetic equator of the earth. Lastly, when the needle is brought exactly over one of the magnetic poles of the earth, it must stand perpendicular to the horizon of that place.

A magnetic needle constructed for the purpose of shewing this property, is called a dipping-needle, and its direction in any place is called the magnetical line. When it was said, that the north pole of the earth possessed south polarity, it was only meant that it had a polarity contrary to that end of the magnetic needle which is directed towards it.

If the geographical poles of the earth (that is, the ends of its axis), coincided with its magnetic poles; or even if the magnetic poles were constantly at the same distance from them; the inclination of the needle, as well as its declination, would always be the same; and hence, by observing the direction of the magnetic needle in any particular place, the latitude and longitude of that place might be ascertained; but this is not the case, for the magnetic poles of the earth do not coincide with its real poles, and they are also constantly shifting their situations; hence the magnetic needle changes continually and irregularly, not only in its horizontal direction, but likewise in its inclination, according as it is removed from one place to another, and also while it remains in the very same place.

This change of the dip in the same place, however, is very small. In London, about 1576, the north pole of the dipping needle stood 71° 50′ below the horizon; and in 1775, it stood at 72° 3′; the whole change of inclination, during so many years, amounting to less than a quarter of a degree.

There are various methods of giving the magnetic property to steel or iron. In some cases, it appears to be acquired without the use of another magnet.

If you take a bar of iron three or four feet long, and hold it in a vertical position, you will find that the bar is magnetic, and will act upon another magnet; the lower extremity of the bar attracting the south pole, and repelling the north pole. If you invert the bar, the polarity will be instantly reversed; the extremity which is now lowest, will be found to be a north pole, and the other extremity will be a south pole.

A bar of hard iron, or steel, will not answer for the above experiment, the magnetism of the earth not being sufficient to magnetise it.

Bars of iron that have stood in a perpendicular position, are generally found to be magnetical; as fire-irons, bars of windows, &c.

If a long piece of hard iron is made red-hot, and then left to cool in the direction of the magnetical line, it becomes magnetical.

Striking an iron bar with a hammer, or rubbing it with a file, while held in this direction, likewise renders it magnetical. An electric shock produces the same effect; and lightning often renders iron magnetic.

A magnet cannot communicate a degree of magnetism stronger than that which itself possesses; but two or more magnets, joined together, may communicate a greater power to a piece of steel, than either of them possesses singly: hence we have a method of constructing very powerful magnets, by first constructing several weak artificial magnets, and then joining them together to form a compound magnet, and to act more powerfully upon a piece of steel.

1. Place two magnetic bars, A, B, fig. 5. in a line with the north, or marked end of one, opposed to the south, or unmarked end of the other; but at such a distance from each other, that the magnet to be touched may rest with its marked end on the unmarked

end of A, and its unmarked end on the marked end of B; then apply the north end of the magnet E, and the south end of D, to the middle of the bar C, the opposite ends being elevated as in the figure; draw E and D asunder along the bar C, one towards A, the other towards B, preserving the same elevation; remove E and D a foot or two from the bar when they are off the ends, then bring the north and south poles of these magnets together, and apply them again to the middle of the bar C as before: repeat the same process five or six times, then turn the bar, and touch the opposite surface in the same manner, and afterwards the two remaining surfaces; by this means the bar will acquire a strong fixed magnetism.

2. Place the two bars which are to be touched parallel to each other; and then unite the ends by two pieces of soft iron, called supporters, in order to preserve, during the operation, the circulation of the magnetic matter; the bars are to be placed so that the marked end D (fig. 6), may be opposite the unmarked end B; then place the two attracting poles G and I on the middle of one of the bars to be touched, raising the ends, so that the bars may form an obtuse angle of 100 or 120 degrees; the ends G and I of the bars are to be separated two or three tenths of an inch from each other. Keeping the bars in this position, move them slowly over the bar A B, from one end to the other, going from end to end about fifteen times. Having done this, change the poles of the bars (*i.e.* the marked end of one is always to be against the unmarked end of the other), and repeat the same operation on the bar C D, and then on the opposite faces of the bars. The touch thus communicated may be further increased, by rubbing the different faces of the bars with sets of magnetic bars, disposed as in fig. 7.

In these operations all the pieces should be well polished, the sides and ends made quite flat, and the angles quite square.

A magnet bent so that the two ends almost meet, is called a horse-shoe magnet, fig. 3. To render it magnetic, place a pair of magnetic bars against the ends of the horse-shoe, with the south end of the bar against that of the horse-shoe which is intended to be the north, and the north end of the bar to that which is to be the south; the contact, or lifter of soft iron, to be placed at the other end of the bars. Also rub the surfaces of the horse-shoe with a pair of bars placed in the form of a compass, or with another horse-shoe magnet, turning the poles properly to the poles of the horse-shoe magnet; being careful that these bars never touch the ends of the straight bars. If the bars are separated suddenly from the horse-shoe magnet, its force will be considerably diminished; to prevent this, slip on the lifter, or support, to the end of the horse-shoe magnet, but in such a manner, however, that it may not touch the bars; the bars may then be taken away, and the support slid to its place.

Magnetism is best communicated to compass-needles by the two following methods:

Procure a pair of magnetic bars, not less than six inches in length. Fasten the needle down on a board, and with a magnet in each hand draw them from the centre upon the needle outwards; then raise the bars to a considerable distance from the needle, and bring them perpendicularly down upon the centre, and draw them over again. This operation repeated about twenty times will magnetize the needle, and its ends will point to the poles contrary to those that touched them.

Over one end of a combined horse-shoe magnet, of at least two in number, and six inches in length, draw from its centre that half of the needle which is to have the contrary pole to the end of the magnet: raise the needle to a considerable distance, and draw it over the magnet again; this repeated about twenty times at least, and the same for the other half, will sufficiently communicate the power.

A set of bars are exceedingly useful for magnetizing other bars, or needles of compasses, &c. their power may also be increased when lost or impaired by mismanagement, &c. A set of such bars, viz. six bars and the two iron conductors, may be preserved in a box; taking care to place the north pole of one contiguous to the south pole of the next, and that contiguous to the north pole of the third, &c. as shewn in fig. 8.

After what has been said above, we need not describe how a knife, or any piece of steel, &c. may be rendered magnetic, or in what manner a weak magnet may be rendered more powerful. But it may perhaps be necessary to say something concerning the communication of magnetism to crooked bars like A B C, fig. 9.

Place the crooked bar flat upon a table, and to its extremities apply the magnetic bars D F, E G; joining their extremities F G, with the conductor or piece of soft iron F G; then to its middle apply the magnetic bars placed at an angle: or you may use two bars only, placed as shewn in fig. 9, and stroke the crooked bar with them from end to end, following the direction of that bent bar; so that on one side of it the magnetic bars may stand in the direction of the dotted representation L K. In this manner, when the piece of steel A B C has been rubbed a sufficient number of times on one side, it must be turned with the other side upwards, &c.

In communicating magnetism, it is best to use weak magnets first, and those that are stronger afterwards; but you must be very careful not to use weak after strong magnets.

A magnet loses nothing of its own power by communicating to other substances, but is rather improved.

Every kind of violent percussion weakens the power of a magnet. A strong magnet has been entirely deprived of its virtue, by receiving several smart strokes of a hammer; indeed, whatever deranges or disturbs the internal pores of a magnet will injure its magnetic force.

Fill a small dry glass tube with iron filings, press them in rather close, and then touch the tube as if it was a steel bar, and the tube will attract a light needle; shake the tube, so that the situation of the filings may be disturbed, and the magnetic virtue will vanish.

Magnets should never be left with two north or two south poles together; for when they are thus placed, they diminish and destroy each other's power. Magnetic bars should therefore be always left with the opposite poles laid against each other, or by connecting their opposite poles by a bar of iron. The power of a magnet is increased by letting a piece of iron remain attached to one or both of its poles. A single magnet should therefore be always thus left.

The difference of steel in receiving magnetism is very great, as is easily proved by touching in the same manner, and with the same bars, two pieces of steel of equal size, but of different kinds. With some sorts of steel, a few strokes are sufficient to impart to them all the power they are capable of receiving; other sorts require a longer operation; sometimes it is impossible to give them more than a small degree of magnetism.

A piece of spring-tempered steel will not retain as much magnetism as hard steel; soft steel still less, and iron retains scarcely any. Iron when oxydated loses its magnetism.

The construction and the use of the principal magnetical instruments, &c.—The magnetical instruments may be reduced to three principal heads; viz. 1st. the magnets or magnetic bars, which are necessary to magnetize needles of compasses, or such pieces of steel, iron, &c. as may be necessary for divers experiments; and which have already been sufficiently explained in the preceding pages: 2dly, the compasses, such as are used in navigation, and for other purposes, which are only magnetic needles justly suspended in boxes, and which, according to the purposes for which they are particularly employed, have several appendages, or differ in size, and in accuracy of divisions, &c. whence they derive the different names of pocket compasses, steering compasses, variation compasses, and azimuth compasses: and 3dly, the dipping-needle.

The magnetic needles which are commonly used at sea, are between four and six inches long; but those which are used for observing the daily variation, are made a little longer, and their extremities point the variation upon an arch or circle properly divided and affixed to the box.

The best shape of a magnetic needle is represented in figs. 10 and 11; the first of which shews the upper side, and the second shews a lateral view of the needle, which is of steel, having a pretty large hole in the middle, to which a conical piece of agate is adapted by means of a brass piece O, into which the agate-cap (as it is called) is fastened. Then the apex of this hollow cap rests upon the point of a pin F, which is fixed in the centre of the box, and upon which the needle, being properly balanced, turns very nimbly. For common purposes, those needles have a conical perforation made in the steel itself, or in a piece of brass which is fastened in the middle of the needle.

A mariner's compass, or compass generally used on board of ships, is represented in fig. 12. The box, which contains the card or fly with the needle, is made of a circular form, and either of wood, or brass, or copper. It is suspended within a square wooden box, by means of two concentric circles, called gimbalds, so fixed by cross axes *a*, *a*, *a*, *a*, to the two boxes (see the plan, fig. 13), that the inner one, or compass-box, shall retain a horizontal position in all motions of the ship, whilst the outer or square box is fixed with respect to the ship. The compass box is covered with a pane of glass, in order that the motion of the card may not be disturbed by the wind. What is called the card (fig. 14), is a circular piece of paper, which is fastened upon the needle, and moves with it. Sometimes there is a slender rim of brass, which is fastened to the extremities of the needle, and serves to keep the card stretched. The outer edge of this card is divided into 360 equal parts or degrees, and within the circle of those divisions it is again divided into 32 equal parts, or arcs, which are called the points of the compass, or rhumbs, each of which is often subdivided into quarters. The initial letters N, N E, &c. are annexed to those rhumbs, to denote the north, north-east, &c The middlemost part of the card is generally painted with a sort of star, whose rays terminate in the above-mentioned divisions. To avoid confusion those letters, &c. are not drawn in the figure.

The azimuth compass is nothing more than the above-mentioned compass, to which two sights are adapted, through which the sun is to be seen, in order to find its azimuth, and from thence to ascertain the declination of the magnetic needle at the place of observation; see fig. 15. The particulars in which it differs from the usual compass, are the sights F, G; in one of which, G, there is an oblong aperture with a perpendicular thread or wire stretched through its middle; and in the other sight F, there is a narrow perpendicular slit. The thread or wire H I is stretched from one edge of the box to the opposite. The ring A B of the gimbalds rests with its pivots on the semicircle C D, the foot E of which turns in a socket, so that whilst the box K L M is kept steady, the compass may be turned round, in order to place the sights F, G, in the direction of the sun.

The pivots of the gimbalds of this, as well as of the common sort of compasses, should lie in the same plane with the point of suspension of the needle, in order to avoid as much as possible the irregularity of the vibrations.

There are, on the inside of the box, two lines drawn perpendicularly along the sides of the box, just from the points where the thread H I touches the edge of the box. These lines serve to shew how many degrees the north or south pole of the needle is distant from the azimuth of the sun; for which purpose, the middle of the apertures of the sights F, G, the thread H I, and the said lines, must be exactly in the same vertical plane. The use of the thread H I, which is often omitted in instruments of this sort, is likewise to shew the degrees between the magnetic meridian and the azimuth, when the eye of the observer stands perpendicularly over it. On the side of the box of this sort of compasses, there generally is a nut or stop, which, when pushed in, bears against the card and stops it, in order that the divisions of the card which coincide with the lines in the box, may be more commodiously read off.

The dipping-needle, though of late much improved, is however still far from perfection. The general mode of constructing it is to pass an axis quite through the needle, to let the extremities of this axis, like those of the beam of a balance, rest upon its supports, so that the needle may move itself vertically round, and when situated in the magnetic meridian, it may place itself in the magnetic line. The degrees of inclination are shewn upon a divided circle, in the centre of which the needle is suspended. Fig. 16 represents a dipping-needle of the simplest construction; A B is the needle, the axis of which F E rests upon the middle of two lateral bars C D, C D, which are made fast to the frame that contains the divided circle A I B K. This machine is fixed on a stand G; but, when used at sea, it is suspended by a ring H, so as to hang perpendicularly. When the instrument is furnished with a stand, a spirit-level O is generally annexed to it, and the stand has three screws, by which the instrument is situated so that the centre of motion of the needle, and the division of 90° on the lower part of the divided circle, may be exactly in the same line, perpendicular to the horizon. See Level.

The few experiments which follow, are principally intended to illustrate the theory.

Ex. 1. The method of discovering whether a body is attractable by the magnet or not, and whether it has any polarity or not, or which is its south, and which its north pole, is so easily performed as not to require many words; for by approaching a magnet to the body in question (which, if necessary, may be set to swim upon water), or by presenting the body in question to either extremity of a suspended magnetic needle, the desired object may be obtained.

Ex. 2. Tie two pieces of soft iron wire, A B, A B, fig. 17 and 18, each to a separate thread, A C, A C, which join at top, and forming them into a loop, suspend them so as to hang freely. Then bring the marked end D fig. 19, which is the north, of a magnetic bar just under them, and the wires will immediately repel each other, as shewn in fig. 18; and this divergency will increase to a certain limit, according as the magnet is brought nearer, and vice versa. The reason of this phenomenon is, that by the action of the north magnetic pole D, both the extremities B, B, of the wires, acquire the same, viz. the south polarity; consequently they repel each other; and the extremities, A, A, acquire the north polarity, in consequence of which they also repel each other.

If instead of the north pole D, you present the south pole of the magnetic bar, the repulsion will take place as before; but now the extremities B, B, acquire the north, and the extremities A, A, acquire the south polarity.

On removing the magnet, the wires, if of soft iron, will soon collapse, having lost all their magnetic power; but if steel wires, or common sewing-needles be used, they will continue to repel each other after the removal of the magnet; the magnetic power being retained by steel.

Ex. 3. Lay a sheet of paper flat upon a table, strew some iron filings upon the paper, place a small magnet among them; then give a few gentle knocks to the table, so as to shake the filings, and you will find that they dispose themselves about the magnet N S, as shewn in fig. 20; the particles of iron clinging to one another, and forming themselves into lines, which at the very poles N, S, are in the same direction with the axis of the magnet; a little sideway of the poles they begin to bend, and then they form complete arches, reaching from some point in the northern half of the magnet, to some other point in the southern half.

Ex. 4. Place a magnetic bar A B, fig. 21, so that one of its poles may project a short way beyond the table, and apply an iron weight C to it; then take another magnetic bar, D E, like the former, and bring it parallel to, and just over the other, at a little distance, and with the contrary poles towards each other; in consequence of which the attraction of B will be diminished, and the iron C, if sufficiently heavy, will drop off, the magnet A B being then only able to support a smaller piece of iron. By bringing the magnets still nearer to each other, the attraction of B will be diminished still farther; and, when the two magnets come quite into contact (provided they are equal in power), the attraction between B and C will vanish entirely; but if the experiment be repeated with this difference, viz. that the homologous poles of the magnets be brought towards each other, then the attraction between B and C, instead of being diminished, will be increased.

MAGNITUDE, whatever is made up of parts locally extended, or that has several dimensions; as a line, surface, solid, &c. The apparent magnitude of a body is that measured by the visual angle, formed by rays drawn from its extremes to the centre of the eye; so that whatever things are seen under the same or equal angles, appear equal; and vice versa.

MAGNOLIA, a genus of the polygynia order, belonging to the polyandria class of plants; and in the natural method ranking under the 52nd order, coadnatæ. The calyx is triphyllous; there are nine petals; the capsules bivalved and imbricated; the seeds pendulous, and in the form of a berry. There are seven species: the principal are,

1. The glauca, or small magnolia, a native of Virginia, Carolina, and other parts of North America. In moist places it rises from seven or eight to fifteen or sixteen feet high, with a slender stem. The wood is white and spongy, the flowers are produced at the extremities of the branches, are white, composed of six concave petals, and have an agreeable scent. 2. The grandiflora, or great magnolia, is a native of Florida and South Carolina. It rises, to the height of eighty feet or more, with a straight trunk upwards of two feet diameter, having a regular head. The leaves resemble those of the laurel, but are larger, and continue green throughout the year. The flowers are produced at the ends of the branches, and are of a purplish-white colour. 3. The tripetala, or umbrella tree, is a native of Carolina; it rises, with a slender trunk, to the height of sixteen or twenty feet; the wood is soft and spongy; the leaves remarkably large, and produced in horizontal circles, somewhat resembling an umbrella, whence the inhabitants of those countries have given it this name. The flowers are composed of ten or eleven white petals, that hang down without any order. The leaves drop off at the beginning of winter. 4. The acuminata, with oval, spear-shaped, pointed leaves, is a native of the inland parts of North America. The leaves are near eight inches long, and five broad, ending in a point. The flowers come out early in the spring, and are composed of twelve white

petals; the wood is of a fine grain, and an orange colour.

MAHERNIA, a genus of the class and order pentandria pentagynia. The cal. is 5-toothed: petals 5; nect. 5 obcordate, placed under the filaments; caps. 5-celled. There are three species, shrubs of the Cape. The incisa is a beautiful little shrub for the greenhouse.

MAIL, or *coat of* MAIL, a piece of defensive armour for the body, made of small iron rings, interwoven in the manner of a net.

MAIM, MAIHEM, or MAYHEM, in law. It is enacted, by the statute of 22 and 23 Car. II. that if any person from malice aforethought, shall disable any limb or member of any of the king's subjects with an intent to disfigure him, the offender, with his aiders and abettors, shall be guilty of felony without benefit of clergy; though no such attainder shall corrupt the blood, or occasion forfeiture of lands, &c.

If a man attack another with an intent to murder him, and he does not murder the man, but only maim him, the offence is nevertheless within the statute 22 and 23 Car. II. c. 1, usually called the Coventry act. 1 Haw. 112.

MAINPRISE, the taking or receiving a man into friendly custody, that otherwise is or might be committed to prison, upon security given for his forthcoming at a day assigned. See BAIL BOND.

MAINTENANCE, is the unlawful taking in hand, or upholding, of a cause or person: this offence bears a near resemblance to barratry, being a person's intermeddling in the suit of another, by maintaining or assisting him with money, or otherwise, to prosecute or defend it. A man may maintain the suit of his near kinsman, servant, or poor neighbour, out of charity or compassion, without being guilty of maintenance. By the common law, persons guilty of maintenance may be prosecuted by indictment, and be fined and imprisoned, or be compelled to make satisfaction by action, &c.; and a court of record may commit a man for an act of maintenance done in the face of the court. 1 Int. 368.

MAJOR, in logic, the first proposition of a syllogism.

MAJOR and MINOR, in music, signify imperfect concords, which differ from each other by a semitone minor.

MALACHODENDRUM, a genus of the class and order monadelphia polyandria. The cal. is simple; germ. pear-shaped, pentagonal; styles, 5; caps. 5, one-seeded: one species, of no note.

MALACHOA, a genus of the class and order monadelphia polyandria. The cal. is common, 3-leaved, many-flowered, longer; arils 5, 1-seeded. There are five species, herbs of the West Indies.

MALACHITE, green carbonat of copper. This ore is often amorphous, but often crystallized in long slender needles.

Colour green. Brittle. Specific gravity 3.571 to 3.653. Effervesces with nitric acid, and gives a blue colour to ammonia. Before the blowpipe it decrepitates and blackens, but does not melt. Tinges borax yellowish green. Tinges flame green.

Variety 1. Fibrous malachite.—Texture fibrous. Opaque when amorphous; when crystallized it is partly transparent is 2. Colour generally grass-green.

Variety 2. Compact malachite.—Texture compact. Opaque. Colour varies from the dark emerald-green to blackish green.

A specimen of malachite from Siberia, analysed by Klaproth, contained

58.0 copper
18.0 carbonic acid
12.5 oxygen
11.5 water
——
100.

This species is sometimes mixed with clay, chalk, and gypsum, in various proportions; it is then known by the name of common mountain-green. Its colour is verdigris-green. Brittle. Texture earthy. Effervesces feebly with acids. Before the blowpipe it exhibits the same phenomena as malachite.

A comparison of the analysis of Klaproth with that of Pelletier seems to prove that malachite contains copper oxidized to a greater degree than blue copper ore.

MALACOLITE. This mineral was first observed in Sweden in the silver-mine of Sahla in Westermania; afterwards in Norway. Colour green. Found massive and crystallized in six-sided prisms, having two opposite edges truncated. Waxy. Texture lamellated. Feel soft. Specific gravity 3.2307. Melts before the blowpipe into a porous glass. According to the analysis of Vauquelin, it is composed of

53 silica
20 lime
19 magnesia
3 alumina
4 oxides of iron and manganese
—
99.

MALATS, in chemistry. This genus of salts is almost unknown, owing chiefly to the difficulty of procuring pure malic acid. The following are the only facts hitherto ascertained.

Malat of potass.
Malat of soda.
Malat of ammonia.

These salts were formed by Scheele. They are deliquescent and very soluble.

Malat of barytes. When malic acid is dropt into barytes water, a white powder precipitates, which is malat of barytes. According to Scheele, the properties of this salt resemble those of malat of lime.

Malat of strontian. Malic acid occasions no precipitate in strontian water. Hence it follows, that malat of strontian is more soluble than malat of barytes.

When malic acid is neutralized with lime, it forms a salt scarcely soluble in water, which may be obtained in crystals, by allowing the supermalat of lime to evaporate spontaneously. Crystals of neutral malat are formed in the solution. But this acid has a strong tendency to combine in excess with lime, and to form a supermalat of lime. This salt is formed when carbonat of lime is thrown into malic acid, or into any liquid containing it. This supersalt exists in various vegetables, especially the sempervivum tectorum, and some of the sedums.

Supermalat of lime has an acid taste. It yields a precipitate with alkalies, sulphuric acid, and oxalic acid. Lime-water saturates the excess of acid, and throws down a precipitate of malat of lime. When the supermalat of lime is evaporated to dryness, it assumes exactly the appearance of gum arabic; and if it has been spread thin upon the nail or wood, it forms a varnish. It is not so soluble in water as gum arabic, and the taste readily distinguishes the two. Supermalat of lime is insoluble in alcohol.

Malat of magnesia. This salt is very soluble in water, and when exposed to the air deliquesces.

Malat of alumina. This salt is almost insoluble in water. Of course it precipitates when malic acid is dropt into a solution containing alumina. Mr. Chenevix has proposed this acid to separate alumina from magnesia; which earths, as is well known, have a strong affinity for each other.

MALAXIS, a genus of the class and order gynandria diandria. The nect. is one-leaved, concave, cordate; acumina, pale, bifid in front. There are two species, bulbs of Jamaica.

MALIC *acid*, obtained from the juice of apples; it is also extracted from the juice of common house-leek, where it exists combined with lime. The process is as follows: To the juice of the house-leek add acetat of lead as long as any precipitate takes place. Wash the precipitate, and decompose it by means of diluted sulphuric acid in the manner directed by Scheele.

Malic acid may be formed also by the action of nitric acid or sugar. If nitric acid is distilled with an equal quantity of sugar, till the mixture assumes a brown colour (which is a sign that all the nitric acid has been abstracted from it), this substance will be found of an acid taste; and after all the oxalic acid which may have been formed is separated by lime-water, there remains another acid, which may be obtained by the following process: saturate it with lime, and filtre the solution; then pour upon it a quantity of alcohol, and a coagulation takes place. This coagulum is the acid combined with lime. Separate it by filtration, and edulcorate it with fresh alcohol; then dissolve it in distilled water, and pour in acetat of lead till no more precipitation ensues. The precipitate is the acid combined with lead, from which it may be separated by diluted sulphuric acid.

Malic acid, thus obtained, is a liquid of a reddish-brown colour and a very acid taste. When evaporated it becomes thick and viscid like a mucilage or syrup, but it does not crystallize. When exposed to a dry atmosphere in thin layers, it dries altogether, and assumes the appearance of varnish. When heated in the open fire it becomes black, swells up, exhales an acrid fume, and leaves behind it a very voluminous coal. When distilled, the products are an acid water, a little carbureted hydrogen gas, and a large proportion of carbonic acid. It is very soluble in water. It gradually decomposes spontaneously, by undergoing a kind of fermentation in the vessels in which it is kept. Sulphuric acid chars it, and nitric acid converts it into oxalic acid. Hence it is evident that it is composed of oxygen, hydrogen, and carbon, though the proportions of these substances have not been ascertained.

Malic acid combines with alkalies, earths, and metallic oxides, and forms salts known by the name of Malats, which see.

Its affinities have not yet been ascertained.

This acid bears a strong resemblance to the citric, but differs from it in the following particulars: 1. The citric acid shoots into fine crystals, but this acid does not crystallize. 2. The salt formed from the citric acid with lime is almost insoluble in boiling water; whereas the salt made with malic acid and the same basis is readily soluble by boiling water. 3. Malic acid precipitates mercury, lead, and silver, from the nitrous acid, and also the solution of gold when diluted with water; whereas citric acid does not alter any of these solutions. 4. Malic acid seems to have a less affinity than citric acid for lime; for when a solution of lime in the former is boiled a minute, with a salt formed from volatile alkali and citric acid, a decomposition takes place, and the latter acid combines with the lime, and is precipitated.

MALLEABLE, a property of metals, whereby they are capable of being extended under the hammer.

MALOPE, a genus of the class and order monadelphia polyandria. The calyx is double, outer three-leaved; arils glomerate, one-seeded. There are two species, herbs of Tuscany, &c.

MALPIGHIA, *Barbadoes cherry*, a genus of the trigynia order, in the decandria class of plants, and in the natural method ranking under the 23d order, trihilatæ. The calyx is pentaphyllous, with melliferous pores on the outside at the base. There are five petals, roundish and unguiculated: the berry unilocular and trispermous. There are 18 species, all of them shrubby evergreens of the warm parts of America, rising with branchy stems from 8 or 10 to 15 or 20 feet high, ornamented with oval and lanceolate entire leaves, and large pentapetalous flowers, succeeded by red, cherry-shaped, eatable berries, of an acid and palatable flavour; and which in the West Indies, where they grow naturally, are used instead of cherries. Three of the species are reared in our gardens, and make a fine variety in the stove. They retain their leaves all the year round; and begin to flower about the end of autumn, continuing in constant succession till the spring; after which they frequently produce and ripen their fruit, which commonly equals the size of a small cherry. The flowers are of a pale-red or purple colour.

MALT, is barley prepared, to fit it for making a potable liquor called beer, or ale, by stopping it short at the beginning of vegetation.

In making malt from barley, the usual method is to steep the grain in a sufficient quantity of water, for two or three days, till it swells, becomes plump, somewhat tender, and tinges the water of a bright-brown, or reddish colour. Then this water being drained away, the barley is removed from the steeping cistern to the floor, where it is thrown into what is called the wet couch; that is, an even heap, rising to the height of about two feet. In this wet couch the capital part of the operation is performed; for here the barley spontaneously heats, and begins to grow, shooting out first the radicle; and if suffered to continue, then the plume, spire, or blade. But the process is to be stopped short at the eruption of the radicle, otherwise the malt would be spoiled. In order to stop it, they spread the wet couch thin over a large floor, and keep turning it once in four or five hours, for the space of two days, laying it somewhat thicker each time. After this, it is again thrown into a large heap, and there suffered to grow sensibly hot to the hand, as it usually will in 20 or 30 hours time; then being spread again, and cooled, it is thrown upon the kiln, to be dried crisp without scorching.

MALTA, KNIGHTS OF, otherwise called *hospitalers of St. John of Jerusalem*, a religious military order, whose residence is in the island of Malta. The order consists of three estates, the knights, chaplains, and servants at arms: there are also priests who officiate in the churches, friar-servants who assist at the offices, and donnes or demicrosses; but these are not reckoned constituent parts of the body: the government of the order is mixt, being partly monarchical, and partly aristocratical: the grand master is sovereign. The knights formerly consisted of eight different languages, but now only seven, the English having withdrawn themselves. None are admitted into this order but such as are of noble birth: the knights are of two sorts, those who have a right to be candidates for the dignity of grand-master, called grand-crosses, and those who are only knights assistants: they never marry. The knights are received into this order, either by undergoing the trials prescribed by statutes, or by dispensation.

MALTHA, in antiquity, a kind of cement of which there were two sorts, native and factitious; one of the latter sort, much in use, consisted of pitch, wax, plaister, and grease. Another kind used by the Romans in their aqueducts, was made of lime slacked in wine, incorporated with melted pitch, and fresh figs. Natural maltha is a kind of bitumen, with which the Asiatics plaister their walls; and which being once set on fire, water makes it burn more fiercely. See BITUMEN.

MALVA, the *mallow*, a genus of the polyandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The calyx is double; the exterior one triphyllous; the arilli numerous and monospermous. There are 34 species, consisting of herbaceous perennials, biennials, and annuals, for medical, economical, and ornamental uses.

The leaves of the common mallow are reckoned the first of the four emollient herbs: they were formerly in some esteem as food; at present decoctions of them are sometimes employed in dysenteries, heat, and sharpness of urine, and in general for obtunding acrimonious humours: their principal use is in emollient glysters, cataplasms, and fomentations. The leaves enter the officinal decoction for glysters, and a conserve is prepared from the flowers. Several pieces of malva, macerated like hemp, afford a thread superior to hemp for spinning, and which is said to make more beautiful cloths and stuffs than even flax. These species are the crispa, Peruviana, and Maurisiana. From the former, which affords stronger and longer fibres, cords and twine have also been made. From the malvæ likewise a new sort of paper has been fabricated by M. de l'Isle.

MAMMÆ, in anatomy, the breasts of a female.

MAMMALIA, in natural history, the first class of animals in the Linnæan system, divided into seven orders. See ZOOLOGY.

MAMMEA, *mammee-tree*, a genus of the monogynia order, in the polyandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is tetrapetalous; the calyx diphyllous; the berry very large and tetraspermous. There is one species, a large evergreen tree of the hot parts of America and Asia, and retained here in hot-houses for variety; adorned with large, oval, oblong, stiff leaves, and large quadripetalous flowers, succeeded by large, round, eatable fruit, of a most exquisitely rich flavour. They are propagated by seed, which is to be sowed in small pots of light earth, and kept in the stove.

MAMMILLARY. See ANATOMY.

MANATI, in zoology. See TRICHECUS.

MANCA, was a square piece of gold coin, commonly valued at 30 pence; and mancusa was as much as a mark of silver, having its name from manu cusa, being coined with the hand (Leg. Canut.). But the manca and mancusa were not always of that value; for sometimes the former was valued at six shillings, and the latter, as used by the English Saxons, was equal in value to our half-crown.

MANDAMUS, is a writ issuing in the king's name out of the court of king's bench, and directed to any person, corporation, or inferior court of judicature, commanding to some particular thing therein specified, as appertaining to their office and duty.

A writ of mandamus is a high prerogative writ, of a most extensive remedial nature, and may be issued in some cases where the injured party has also another more tedious method of redress, as in the case of admission or restitution to an office; but it issues in all cases where the party has a right to have any thing done, and has no other specific means of compelling its performance. 3 Black. 100.

And this general jurisdiction and superintendance of the king's bench over all inferior courts to restrain them within their bounds, and to compel them to execute their jurisdiction, whether such jurisdiction arises from a modern charter, subsists by custom, or is created by act of parliament, yet being in subsidium justitiæ, has of late been exercised in a variety of instances.

Mandamus was also a writ that lay after the year and a day (where, in the mean time, the writ called diem clausit extremum had not been sent out) to the escheator, commanding him to enquire of what lands holden by knight-service the tenant died seized, &c. F. N. B. 561.

Mandamus was also a writ to charge the sheriff to take into the king's hands all the lands and tenements of the king's widow, who, against her oath formerly given, marries without the king's consent. Reg. 295.

MANETTIA, a genus of the class and order tetrandria monogynia. The calyx is eight-leaved; corolla four-cleft; capsule inferior, two-valved, one-celled; seeds imbricate, unilocular. There are three species, shrubs of the West Indies.

MANGANESE. I. The dark-grey or brown mineral called manganese has been long known and used in the manufacture of glass. A mine of it was discovered in England by Mr. Boyle. A few experiments were made upon this mineral by Glauber in 1656, and by Waitz in 1705; but chemists in general seem to have paid but very little attention to it. The greater number of mineralogists, though much puzzled what to make of it, agreed in placing it among iron ores: but Pott, who published the first chemical examination of this mineral in 1740, having ascertained that it often contains scarcely any iron, Cronstedt, in his System of Mineralogy, which appeared in 1758, assigned it a place of its own, on the supposition that it consisted chiefly of a peculiar earth. Rinman examined it anew in 1765; and in the year 1770 Kaim published at Vienna a set of experiments, in order to prove that a peculiar metal might be extracted from it. The same idea had struck Bergman about the same time, and induced him to request of Scheele, in 1771, to undertake an examination of manganese. Scheele's dissertation on it, which appeared in 1774, is a masterpiece of analysis, and contains some of the most important discoveries of modern chemistry. Bergman himself published a dissertation on it the same year; in which he demonstrates that the mineral, then called manganese, is a metallic oxide. He accordingly made several attempts to reduce it, but without success; the whole mass either assuming the form of scoriæ, or yielding only small separate globules attracted by the magnet. This difficulty of fusion led him to suspect that the metal he was in quest of bore a strong analogy to platinum. In the mean time Dr. Gahn, who was making experiments on the same mineral, actually succeeded in reducing it by the following process: he lined a crucible with charcoal-powder moistened with water, put into it some of the mineral formed into a ball by means of oil, then filled up the crucible with charcoal-powder, luted another crucible over it, and exposed the whole for about an hour to a very intense heat. At the bottom of the crucible was found a metallic button, or rather a number of small metallic globules, equal in weight to one-third of the mineral employed. It is easy to see by what means this reduction was accomplished. The charcoal attracted the oxygen from the oxide, and the metal remained behind. The metal obtained, which is called manganese, was farther examined by Ilseman in 1782, Hielm in 1785, and Bindheim in 1789.

Manganese, when pure, is of a greyish-white colour, and has a good deal of brilliancy. Its texture is granular. It has neither taste nor smell. Its hardness is equal to that of iron. Its specific gravity is 7.000. It is very brittle; of course it can neither be hammered, nor drawn out into wire. Its tenacity is unknown. It requires, according to Morveau, the temperature of 160° Wedgewood to melt it; so that, platinum excepted, it is the most infusible of all the metals. When reduced to powder it is attracted by the magnet, owing probably to a small portion of iron from which it can with difficulty be parted.

II. Manganese, when exposed to the air, attracts oxygen more rapidly than any other body, phosphorus excepted. It loses its lustre almost instantly, becomes grey, violet, brown, and at last black. These changes take place still more rapidly if the metal is heated in an open vessel.

This metal seems capable of combining with three different proportions of oxygen, and of forming three different oxides, the white, the red, and the black.

The protoxide or white oxide may be obtained by dissolving the black oxide of manganese in nitric acid by adding a little sugar. The sugar attracts oxygen from the black oxide, and converts it into the white, which is dissolved by the acid. Into the solution pour a quantity of potass; the protoxide precipitates in the form of a white powder. It is composed, according to Bergman, of 80 parts of manganese and 20 of oxygen. When exposed to the air it soon attracts oxygen, and is converted into the black oxide.

The deutoxide or red oxide may be obtained by dissolving the black oxide in sulphuric acid, without the addition of any combustible substance. When black oxide of manganese, made into a paste with sulphuric acid, is heated in a retort, a great quantity of oxygen gas comes over, while the oxide, thus deprived of part of its oxygen, dissolves in the acid. Distil to dryness, and pour water upon the residuum, and pass it through a filtre. A red-coloured solution is obtained, consisting of the sulphat of manganese dissolved in water. On the addition of an alkali a red substance precipitates, which is the red oxide of manganese. According to Bergman it is composed of 74 parts of manganese and 26 of oxygen. This oxide likewise attracts oxygen when exposed to the atmosphere, and is converted into the black oxide.

The peroxide of black oxide of manganese exists abundantly in nature; indeed it is almost always in this state that manganese is found. It was to the black oxide that the appellation manganese itself was originally applied. It may be formed very soon by exposing the metal to the air. This oxide, according to Fourcroy, is composed of 60 parts of manganese and 40 of oxygen. When heated to redness in an earthen retort it gives out abundance of oxygen gas, which may be collected in proper vessels. By this operation it is reduced nearly to the state of red oxide. If it is exposed to the air, and moistened occasionally, it absorbs a new dose of oxygen; and thus the same process may again be repeated. No oxygen gas can be obtained from the white oxide: a proof that its oxygen is retained by a stronger affinity than the additional dose of oxygen which constitutes the black oxide. Seguin has observed, that in some cases the black oxide of manganese emits, before it becomes red, a quantity of azotic gas. When long exposed to a strong heat it assumes a green colour. In that state it is whitened by sulphuric acid, but not dissolved. A very violent heat fuses this oxide, and converts it into a green-coloured glass.

III. Manganese does not combine with hydrogen. When dissolved in sulphuric acid a black spongy mass of carburet of iron is left behind. Hence it has been supposed capable of combining with carbon; but it is more probable that the carbon is combined with the iron, which is almost always present in manganese. It seems pretty clear, however, that carburet of iron is capable of combining with this metal, and that it always forms a part of steel.

Bergman did not succeed in his attempt to combine manganese with sulphur; but he formed a sulphureted oxide of manganese, by combining eight parts of the black oxide with three parts of sulphur. It is of a green colour, and gives out sulphureted hydrogen gas when acted on by acids. It cannot be doubted, however, that sulphur is capable of combining with manganese; for Proust has found native sulphuret of manganese in that ore of tellurium which is known by the name of gold ore of Nagyag.

Phosphorus may be combined with manganese by melting together equal parts of the metal and of phosphoric glass; or by dropping phosphorus upon red-hot manganese. The phosphuret of manganese is of a white colour, brittle, granulated, disposed to crystallize, not altered by exposure to the air, and more fusible than manganese. When heated the phosphorus burns, and the metal is oxidized.

IV. Manganese does not combine with either of the simple combustibles.

V. Manganese combines with many of the metals, and forms with them alloys which have been but very imperfectly examined.

It unites readily with copper. The compound, according to Bergman, is very malleable, its colour is red, and it sometimes becomes green by age. Gmelin made a number of experiments to see whether this alloy could be formed by fusing the black oxide of manganese along with copper. He partly succeeded, and proposed to substitute this alloy instead of the alloy of copper and arsenic, which is used in the arts.

It combines readily with iron; indeed it has scarcely ever been found quite free from some mixture of that metal. Manganese gives iron a white colour, and renders it brittle. It combines also with tin, but scarcely with zinc.

It does not combine with mercury nor with bismuth. Gmelin found that manganese cannot be alloyed with bismuth without great difficulty; and that it unites to antimony very imperfectly. Chemists have not attempted to combine it with gold, platinum, silver, nickel, nor cobalt.

VI. The affinities of manganese, and of its white and red oxides, are, according to Bergman, as follows:

Manganese.	*Oxide of manganese.*
Copper,	Oxalic acid,
Iron,	Citric,
Gold,	Phosphoric,
Silver,	Tartaric,
Tin.	Fluoric,
	Muriatic,
	Sulphuric,
	Nitric,
	Saclactic,
	Succinic,
	Tartaric,
	Lactic,
	Acetic,
	Prussic,
	Carbonic.

MANGIFERA, the *mango-tree*, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is pentapetalous; the plum kidney-shaped. There are three species, the principal of which is a native of many parts of the East Indies, whence it has been transplanted to Brazil, and other warm parts of America. It grows to a large size;

the wood is brittle; the bark rough when old; the leaves are seven or eight inches long, and more than two inches broad. The flowers are produced in loose panicles at the ends of the branches, and are succeeded by large oblong kidney-shaped plums. This fruit, when fully ripe, is greatly esteemed in the countries where it grows; but in Europe we have only the unripe fruit brought over in pickle. All attempts to propagate the plant have hitherto proved ineffectual; and Mr. Millar is of opinion that the stones will not vegetate unless they are planted soon after they are ripe.

MANICHEES, in church history, a sect of christian heretics in the third century, the followers of Manes, who made his appearance in the reign of the emperor Probus; pretending to be the Comforter, whom our Saviour promised to send into the world. He taught that there are two principles, or gods, coeternal and independant on each other; the one the author of all evil, and the other of all good: a doctrine which he borrowed from the Persian magi. He held that our souls were made by the good principle, and our bodies by the evil one; and that the souls of his followers passed through the elements to the moon, and from thence to the sun, where being purified, they then went to God, and became united with his essence; but as for the souls of other men, they either went to hell, or were united to other bodies.

MANILLE, in commerce, a large brass ring, in the form of a bracelet, either plain or engraven, flat or round. Manilles are the principal commodities which the Europeans carry to the coast of Africa, and exchange with the natives for slaves. These people wear them as ornaments on the small of the leg, and on the thick part of the arm above the elbow. The great men wear manilles of gold and silver, but these are made in the country by the natives themselves.

MANIPULUS, in Roman antiquity, a body of infantry, consisting of 200 men, and constituting the third part of a cohort. See COHORT.

MANIS, a genus of quadrupeds of the order of bruta. The generic character is, teeth none; tongue cylindric and extensile; mouth narrowed into a snout; body covered with scales. The genus manis presents an appearance not less extraordinary than that of dasypus or armadillo; being covered on every part, except on the belly, with extremely strong and large horny scales, constituting a suit of armour still more powerful than in the following genus, and capable of defending the animals, when rolled up, from the assaults of the most ferocious enemies. This external covering, together with the uncommon length of the body and tail, gives an aspect so much resembling that of a lizard, that these creatures are commonly known by the title of scaly lizards: they may be allowed, however, in a general view of the animal kingdom, to form a kind of shade or link of approximation between the proper viviparous quadrupeds and the lizards.

They are animals of a harmless nature, and feed in the same manner as the ant-eaters, by thrusting out their very long tongue into the nests of ants and other insects, and swallowing their prey by suddenly retracting it, having no teeth, and differing from the ant-eaters in scarcely any other circumstance than that of their scaly integument. They are found in India and the Indian islands.

1. Manis tetradactyla, long-tailed manis. This animal, known in India by the name of the phatagen, is of a very long and slender form: the head is small; the snout narrow; the whole body, except beneath, covered with broad, but sharp-pointed, scales, which are striated throughout their whole length: the tail is more than twice the length of the body, and tapers gradually to the tip. The legs are very short, scaled like the body, and on each of the feet are four claws, of which those on the fore feet are stronger than those of the hind. The colour of the whole animal is an uniform deep-brown, with a cast of yellowish, and with a glossy or polished surface. The manis tetradactyla grows to the length of five feet, measuring from the tip of the nose to the extremity of the tail.

2. Manis pentadactyla, short-tailed manis, differs from the former, in being of a much thicker and shorter form; the tail, in particular, differs greatly in proportion from that of the preceding, being not so long as the body, very thick at the base, and thence gradually tapering, but terminating very obtusely. The head is small as in the former; the ears small and rounded; the feet furnished with five toes each, of which those on the fore feet are extremely strong, except the exterior one, which is much smaller than the rest. The whole animal is covered with most extremely thick, strong, and large scales, which in the full-grown specimens are perfectly smooth, but in those which are smaller are slightly striated about half way from the base. Sometimes a few bristles appear between the scales, but in others this is not observable. The scales differ in shape from those of the preceding, being much wider and larger in proportion to the body and tail. The colour of the whole animal is a very pale yellow-brown, and the surface is glossy, as in the former species. In India it is called the pangoelling. In the neighbourhood of Bengal it is named vajracite, or the thunderbolt reptile, from the excessive hardness of the scales, which are said to be capable even of striking fire like a flint. It is said to walk slowly; but, when pursued, rolls itself up, and is then so securely armed, that even a leopard attacks it in vain. It is also said sometimes to destroy the elephant, by twisting itself round the trunk, and thus compressing that tender and sensible organ with its hard scales. We are told in the Asiatic Researches that the Malabar name of this animal is alungu; and that the natives of Bahar call it bajar-cit, or the stone vermin; and in the stomach of the one examined and described in the above work was found about a teacupful of small stones, which it is supposed to have swallowed for the purpose of facilitating digestion. It was only 34 inches long from the nose to the end of the tail; and a young one was found in it.

Specimens of the manis pentadactyla have sometimes been seen of the length of six feet from the nose to the tip of the tail. See Pl. Nat. Hist. fig. 258.

MANNA, in natural history. This substance exudes from the fraxinus ornus, in the months of June and July, from the stem and branches. It is at first liquid, but gradually becomes solid. It is collected in Sicily and the southern parts of Italy. It is in form of oblong globules of a whitish-yellow colour, and somewhat transparent. It is very light. Its taste is sweet, and it leaves a nauseous bitter impression in the mouth. Its properties have not been examined by chemists. It acts as a mild cathartic. See MATERIA MEDICA.

MANOMETER, or MANOSCOPE, an instrument to shew or measure the alterations in the rarity or density of the air. The manometer differs from the barometer in this, that the latter only serves to measure the weight of the atmosphere, or of the column of air over it, but the former the density of air in which it is found; which density depends not only on the weight of the atmosphere, but also on the action of heat and cold, &c. Authors, however, generally confound the two together; and Mr. Boyle himself gives us a very good manometer of his contrivance, under the name of a statical barometer, consisting of a bubble of thin glass, about the size of an orange, which, being counterpoised when the air was in a mean state of density, by means of a nice pair of scales, sunk when the atmosphere became lighter, and rose as it grew heavier. See METEOROLOGY.

MANOR, was a district of ground held by lords or great personages, who kept in their own hands so much land as was necessary for the use of their families, which were called terræ dominicales, or demesne lands, being occupied by the lord, or dominus manerii, and his servants. The other lands they distributed among their tenants, which the tenants held under divers services. The residue of the manor being uncultivated was termed the lord's waste, and served for common of pasture to the lord and his tenants. All manors existing at this day must have existed as early as king Edward the First. 2 Black. 90. See COURT BARON.

MANSLAUGHTER, is unlawfully killing a man without any malice prepense, or forethought. The English law very humanely makes a distinction between a hasty and deliberate act: as when two persons on a sudden quarrel, fight, and one is killed; yet as it is done in a sudden heat of passion, and not with any premeditated malice, it is manslaughter, and not murder. See MURDER.

This crime may be either voluntary, as on a sudden loss of temper; as if a man is greatly provoked, and kills the aggressor, it is manslaughter; but if it appears that there was a sufficient cooling time for the heat of anger to subside, this shews deliberate revenge, and amounts to murder. Or it may be involuntary, but in the commission of some unlawful act; in which latter respect it differs from homicide per infortunium: as if one shoots off a gun in a highway, and where people often meet, and kills a man; or if he is shooting at game, and is not qualified or licensed, and kills another, it is manslaughter. And, in general, when an involuntary killing happens, in consequence of an unlawful act, it will be murder or manslaughter, according to the act which occasioned it.

It is evident from the nature of this crime that there can be no accessaries, because it must be done without premeditation; but when two men once fell out, and immediately fought, and the sword of one was broken, and his friend lent him another, with which he killed his antagonist, it was made manslaughter in both. Again: there were two men in a room quarreling; a brother of one of them standing at the door, who could not get in, cried out to his brother to make him sure, and the brother killed his antagonist: it was likewise manslaughter in both.

But if any person shall stab another, not having his weapon drawn, or not strucken first, so that he dies within six months, although it be not of malice aforethought, it is felony without benefit of clergy.

This crime, though felony, is within benefit of clergy; and the offender shall be burnt in the hand, and forfeit all his goods and chattels; but by stat. 19 Geo. III. c. 74, it is made lawful for the court to commute this punishment for a moderate fine and imprisonment.

MANTELETS, in the art of war, a kind of moveable parapets, made of planks about three inches thick, nailed one over another, to the height of almost six feet, generally cased with tin, and set upon little wheels, so that in a siege they may be driven before the pioneers, and serve as blinds to shelter them from the enemy's small shot.

MANTIS, a genus of insects of the order hemiptera. The generic character is, head unsteady, armed with jaws, and furnished with palpi or feelers; antennæ setaceous; thorax linear; wings four, membranaceous, convoluted, the lower pair pleated; fore legs, in most species, compressed, serrated beneath, and armed with a single claw and a setaceous, lateral, jointed foot; hind legs smooth, formed for walking. This is one of the most singular genera in the whole class of insects; and imagination itself can hardly conceive shapes more strange than those exhibited by some particular species. See Pl. Nat. Hist. fig. 259.

The chief European kind is the mantis oratoria of Linnæus, or camel cricket, as it is often called. This insect, which is a stranger to the British isles, is found in most of the warmer parts of Europe, and is entirely of a beautiful green colour. It is nearly three inches in length, of a slender shape, and in its general sitting posture is observed to hold up the two fore legs, slightly bent, as if in an attitude of prayer: for this reason the superstition of the vulgar has conferred upon it the reputation of a sacred animal; and a popular notion has often prevailed, that a child or traveller having lost his way would be safely directed by observing the quarter to which the animal pointed when taken into the hand. In its real disposition it is very far from sanctity, preying with great rapacity on any of the smaller insects which fall in its way, and for which it lies in wait with anxious assiduity in the posture at first mentioned, seizing them with a sudden spring when within its reach, and devouring them. It is also of a very pugnacious nature; and when kept with others of its own species in a state of captivity, will attack its neighbour with the utmost violence, till one or the other is destroyed in the contest.

Among the Chinese this quarrelsome property in the genus mantis is turned into a similar entertainment with that afforded by fighting cocks and quails.

The mantis precaria is a native of many parts of Africa, and is the supposed idol of the Hottentots, which those superstitious people are reported to hold in the highest veneration, the person on whom the adored insect happens to light being considered as favoured by the distinction of a celestial visitant, and regarded ever after in the light of a saint. This species is of the same general size and shape with the M. oratoria, and is of a beautiful green colour, with the thorax ciliated or spined on each side, and the upper wings each marked in the middle by a semitransparent spot.

Of all the mantes perhaps the most singular in its appearance is the mantis gongylodes of Linnæus, which, from its thin limbs, and the grotesque form of its body, especially in its dried state, seems to resemble the conjunction of several fragments of withered stalks. There are 14 species of this genus.

MANTLE, or MANTLING, in heraldry, that appearance of folding of cloth, flourishing, or drapery, that is in any achievement drawn about the coat of arms.

MANURE, any thing used for fattening and improving land. See HUSBANDRY.

MAP, a plane figure, representing the surface of the earth, or a part thereof.

In maps these three things are essentially requisite. 1. That all places have the same situation and distance from the great circles therein, as on the globe, to shew their parallels, longitudes, zones, climates, and other celestial appearances. 2. That their magnitudes be proportionable to their real magnitudes on the globe. 3. That all places have the same situation, bearing, and distance, as on the earth itself.

The true chart performs the first and last of these very exactly, but fails extravagantly in the second; and indeed no kind of projection yet found can exhibit more than two of them at once, by reason of the great difference between a plane and convex superficies.

Maps are not always to be used as they lie before us, for sometimes any part is uppermost; but, generally, the top is the north part, the bottom the south, the right hand the east, and the left hand the west, and marked with these words, or Latin ones of the same import. There is also inscribed a compass, pointing to all the quarters of the world, the north one being marked with a flower-de-luce.

The degrees of longitude are always numbered at top and bottom, and the degrees of latitude on the east and west sides. In all right-lined and general circular maps, except those of Wright's projection, the degrees of latitude on the sides are of an equal breadth; and in all circular and right-lined maps, except the said Wright's, and the plane charts, the degrees of longitude are unequal.

In general maps the circles corresponding to those in the heavens are inscribed, viz. the equator is expressed by a straight east and west line; and the first meridian, the polar circles, the tropics, and the other meridians and parallels, which are drawn at every five or ten degrees, intersect each other at right angles.

The most natural method of representing a sphere upon a plane seems to be, to divide it into two equal parts, and inscribe each of them in a circle: but as the equator, and the polar axis, which intersects that circle at right angles, and makes one of the meridians, must be supposed equal in length to the half of the periphery (which is not quite two-thirds), it follows of course, that the countries delineated upon, or near, these lines, must be reduced to somewhat less than two-thirds of the size of the countries of equal extent, which lie at the extremity of the circle; and that the lines drawn to measure the latitude, which are parallel to each other, or nearly so, must, in order to preserve as nearly as possible their proportional angles at the points of intersection with the meridians, form segments of circles, of which no two are parallel or concentric.

There may be as many different projections as there are points of view in which a globe can be seen, but geographers have generally chosen those which represent the poles at the top and bottom of the map; these, from the delineation of the lines of latitude and longitude, are called the stereographic, orthographic, and globular projections.

We do not propose to detain the reader with a description of all the projections, some of which are so erroneous (for the purpose of constructing of maps) as to deserve being consigned entirely to oblivion. But as the projection of maps is a pleasing and instructive exercise, and indeed indispensably necessary to the right understanding of geography to students, we shall describe the manner of constructing the map of the world. With regard to the stereographic projection it may be observed, that among the various positions assignable to the eye there are chiefly two that have been adopted, wherein the eye is placed either in the points D, fig. 1, or removed to an infinite distance; and hence this projection is liable to the great error of distorting the form of the countries represented upon it much more than is necessary. The only advantage is, that the lines of latitude and longitude intersect each other at right angles.

This being observed by that excellent astronomer, M. de la Hire, he invented a remedy for the inconvenience, by assigning to the eye a position at the point O, fig. 1, the distance of which from the globe at D is equal to the right sine of 45 degrees; and hence the right line GO, which bisects the quadrant BC, also bisects the radius EC, and produces the similar triangles OFG, and OEI; and thus the other parts of the quadrant EC, and in like manner of the whole semicircle AEC, are represented in the projection nearly proportionable to each other, and to sense perfectly so. The delineation of the earth and sea upon this projection (which, as coming the nearest to a true representation of the globe, is called the globular projection), is equal to the stereographic in point of facility, and vastly superior to it in point of truth.

Geometrical construction of the globular projection.—From the centre C, fig. 2, with any radius, as CB, describe a circle; draw the diameters AB, and 90, 90, at perfect right angles to one another, and divide them into nine equal parts; likewise divide each quadrant into nine equal parts, each of which contains ten degrees; if the scale admits of it, every one of these divisions may be subdivided into degrees: next, to draw the meridians, suppose the meridian 80° W. of Greenwich, we have given the two poles 90, 90, and the point 80 in the equator, or diameter AB; describe a circle to pass through the three given points as follows: with the radius 90 set one foot of the compasses on the point 90, and describe the semicircles XX and ZZ, then remove the compasses to the point 80 on the equator, and describe the arcs 1, 1, and 2, 2; where they intersect the semicircle make the point, as at 1 and 2, and draw lines from 2 through the point 1 till they intersect the diameter BA continued in E: then will E be the centre from whence the meridian 90, 80, 90, must be drawn, and will express the meridian of 80° W. longitude from Greenwich; the same radius will draw the meridian expressing 140° W. longitude, in like manner: draw the next meridian with the radius CB, set one foot of the compasses in the point *d*, and describe the arcs *aa* and *bb*, then draw lines as before, which will give the point D, the centre of 90° W. longitude; so of all the rest.

The parallels of latitude are drawn in the same manner, with this difference, that the semicircles XX and ZZ must be drawn from the points A and B, the extremities of the equator.

In the manner above described, with great labour and exactness, Mr. Arrowsmith, to whom we are indebted for a part of this article, drew all the meridians and parallels of latitude to every degree on two hemispheres, which laid the foundation of his excellent map of the world.

We shall now proceed to shew how the same thing may be done mechanically, both with regard to the globular and stereographic projection.

(1) *The Globular Projection of the Sphere on the Plane of a Meridian.*

Draw the circle WNES, fig. 3, draw the two diameters NS and WE at right angles with each other.

Divide the are of eaeh quadrant into nine equal parts.

Divide the radii also in the same manner into ninety equal parts each.

The diameter NS is the meridian, and the diameter WE is the equator.

The other meridians are arcs of circles, for each of which, as we have seen, there are three given points through which it must pass, and those are the two poles NS, and a division on the semi-diameter WC, viz. either *a*, *b*, *c*, *d*, *e*, *f*, *g*, or *h*. The centres for these arcs will be in the line CE produced; and the centres for those on the other side, will be on the line CW produced.

For the arc		the radius		
SaN.	the radius	*aa*	=	90,61
— SbN.	—	*bb*	=	92,82
— ScN.	—	*cc*	=	97,32
— SdN.	—	*dd*	=	106
— SeN.	—	*ee*	=	121,1
— SfN.	—	*ff*	=	149,7
— SgN.	—	*gg*	=	215.6
— ShN.	—	*hh*	=	410,7

Of the = parts of which the radius contains 90.

And for each of the arcs representing the parallels of lat also there are three given points; viz. one of the divisions *k*, *l* *m*, *n*, *o*, *p*, *q*, or *r*, upon the meridian SN, and the two corresponding divisions of the circumference. The centres for these arcs will fall on the line SN, produced both ways, and the following table shews the length of the radius of each equal part, in equatorial degrees, as in the former ease.

For the arc

80	*r* 80	the radius	*rr*	=	18,44	
70	*q* 70	—	*qq*	=	39.75	
66½	A. 66½	—	A. *Arctic*	=	48,19	
60	*p* 60	—	*pp*	=	65.3	
50	*o* 50	—	*oo*	=	97,71	
40	*n* 40	—	*nn*	=	143	
30	*m* 30	—	*mm*	=	210	
23½	T. 23½	—	T. *Tropic*	=	281,4	
20	*l* 20	—	*ll*	=	337,5	
10	*k* 10	—	*kk*	=	703,5	

Of the equal parts of which the radius contains 90.

(2) *The Stereographic Projection of the Sphere on the Plane of a Meridian.*

Draw a circle NESW, fig. 4, and the two diameters of it at right angles with each other.

Divide the arc of each quadrant into nine equal parts.

From the point E, draw dotted lines to each point of division on the arc WN.

The intersections made by this means on the semidiameter CN, mark a line of semitangents, which must also be set off on the other three semidiameters, CS, CW and CE.

Draw likewise two dotted lines from E to 23½° and 66½° for the tropic and polar arcs, which must also be set off on the semi-diameter CS.

Each point of intersection on CN, and the corresponding divisions on the arcs WN and EN, are the three points through which the arcs of latitude must pass; and their centres will be in the line NS produced.

Take the radius of the same circle for a scale; divide it into nine equal parts, and each of those parts into ten other parts, as before

The following table exhibits the length in those parts of the radius, which must be taken to describe eaeh respective arc.

For the arc

80	*r* 80	the radius	*rr*	=	15,87
70	*s* 70	—	*ss*	=	32,75
66½	A. 66½	—	A. *Arctic*	=	39,19
60	*t* 60	—	*tt*	=	51,96
50	*v* 50	—	*vv*	=	75,52
40	*w* 40	—	*ww*	=	107,3
30	*x* 30	—	*xx*	=	155,9
23½	T. 23½	—	T. *Tropic*	=	207
20	*y* 20	—	*yy*	=	247,3
10	*z* 10	—	*zz*	=	510,4

Of the equal parts of which the radius contains 90.

The two polar points N, S, and the semitangents on CE, mark the three given points through which each meridian line must pass.

The following table exhibits the length of each radius to describe the meridian arcs.

For the arc		the radius		
NaS.	the radius	*aa*	=	91,4
— NbS.	—	*bb*	=	95,78
— NcS.	—	*cc*	=	104
— NdS.	—	*dd*	=	117,5
— NeS.	—	*ee*	=	140
— NfS.	—	*ff*	=	180
— NgS.	—	*gg*	=	263
— NhS.	—	*hh*	=	513,3

Of the = parts of which the radius contains 90.

(3) *The Globular Projection of the Sphere on the Plane of the Equator.*

On the eentre P, fig. 5, draw the circle WNES, to represent the equator.

Draw the two diameters, WE and NS, at right angles with each other.

Divide the arcs of the four quadrants into nine equal parts; each of the parts will be equal to ten degrees.

Number them from N towards P, 10, 20, 30, 40, 50, &c.

On the centre P draw circles passing through those points of division, which will be the circles of latitude.

For the arctic circle, set off 23½° from P towards N; do the same at N towards P, for the tropic eircle.

Through each of those points draw an obscure circle.

Draw diameters from the divisions on one half of the eircumference to the corresponding divisions on the opposite one, to represent the meridians, and this will complete the projection.

(4) *The Stereographic Projection of the Sphere on the Plane of the Equator.*

Draw the circle N, W, S, E, fig. 6, and the two diameters at right angles with each other.

Divide the arcs of each of the four quadrants into nine equal parts; subdivide each of those parts into 10 degrees; number those degrees 10, 20, 30, &c.

Draw diameters from the divisions on one side of the circumference to the corresponding divisions on the other, which will represent the meridians.

For the parallels of latitude, project a line of semitangents as directed in the 2d ease.

On the centre P describe circles passing through the semitangents, which will complete the diagram.

Note. The foregoing methods of projecting the sphere are the best. There is another method sometimes used, viz. the projection on the plane of the horizon when any assumed place is considered as the centre; but as this method is rarely used, it need not be elucidated.

The orthographic projection is in fact so erroneous, that it ought to be entirely rejected for that purpose, and applied only to dialling.

The gnomonical projection is only applicable to dialling.

We shall now point out the advantage and disadvantage of Mercator's projection.

A method has been found to obviate some of the difficulties attending all the circular projections by one, which, from the person who first used it (though not the inventor), is called Mercator's projection. In this there are none but right lines: all the meridians are equidistant, and continue so through the whole extent; but, on the other hand, in order to obtain the true bearing, so that the compass may be applied to the map (or chart) for the purpose of navigation, the spaces between the parallels of latitudes (which in truth are equal, or nearly so) are made to increase as they recede from the equator in a proportion which, in the high latitudes, becomes prodigiously great.

The great advantages peculiar to this projection are, that every place drawn upon it retains its true bearing with respect to all other places; the distances may be measured with the nicest exactness by proper scales, and all the lines drawn upon it are right lines: for these reasons it is the only projection in drawing maps or charts for the use of navigators. We shall shew the method of this kind of projection.

Mercator's or Wright's projection of maps.—Draw the line AB, fig. 7, and divide it into as many degrees as your map is to contain in longitude, suppose 90°. At the extremities A and B raise perpendiculars, to which draw parallel lines at every single, fifth, or tenth degree of the equator, for the meridians; as in the figure, where they are drawn at every tenth degree. This done, put one foot of the compasses in the point A, and extending the other to the point in the first meridian in the equator G; or, for greater exactness, to some more distant point, as B 90; describe the quadrant FB, when divide into nine equal parts, and drawn lines from A to each point of the division; or, to avoid scoring the paper, only mark where a ruler cuts the first meridian GH, at every tenth degree's distance. Lastly, because the distances of the parallels from one another are marked, by this means, in the line GH, you must transfer them from that line to the side lines AC, BD, after the following manner: 1. Set one foot of the compasses in A, and extending the other to the first point above G, marked 1, transfer this distance, viz. A 1, to the lines AC, BD, and draw a line parallel to the equator AB, for the tenth parallel. 2. Next transfer the distance A 2 into the lines AC, BD, from the 10th parallel to the 20th, which is to be drawn. 3. In the same manner the distances A 3, A 4, A 5, &c. laid off upon the lines AC, BD, from the immediately preceding parallels, viz. 20, 30, 40, &c. will successively point out where the parallels 30, 40, 50, &c. are to be drawn.

This is the geometrical projection, which may also be laid down by means of a scale or table of meridional parts, by the line of secants, &c.

This projection supposes the earth, instead of a globular, to have a cylindrical figure; in consequence of which, the degrees of longitude become of an equal length throughout the whole surface, and are marked out on the map by parallel lines. The circles of latitude also are represented by lines crossing the former at right angles, but at unequal distances. The further we remove from the equator, the longer the degrees of latitude become in proportion to those of longitude, and that in no less a degree than as the secant of an arch to the radius of the circle; that is, if we make one degree of longitude at the equator the radius of a circle; at one degree distant from the equator, a degree of latitude will be expressed by the secant of one degree; at ten degrees distance, by the secant of ten degrees, and so on. A map of the world, therefore, cannot be delineated upon this projection, without distorting the shape of the countries in an extraordinary manner. The projection itself is, however, as we have already observed, very useful in navigation, as it shows the different bearings with perfect accuracy, which cannot be done upon any other map.

We shall now add a more exact method of projecting particular maps, wherein the squares are so projected as to form equal diagonals throughout.

Of the projection of maps of particular parts of the world.—There are several methods of projecting particular parts of the world, we shall notice only two. First, when the meridians and parallels of latitude are right lines.

To project a map of England after this method.—England is situated between 2° E. and 6° 20′ W. from Greenwich, and between 50° and 56° N. lat.

Draw a base line AB, fig. 8, in the middle of which erect the perpendicular CD.

Assume a distance for a degree of lat. and set off as many degrees on CD as are wanted, which in this instance are 6; but as a little space beyond the limits of the country is generally left, set off 7.

Through these points draw lines parallel to AB, which will be parallels of latitude.

Respecting the degrees of longitude it must be observed, that on the equator they would be of the same length as they are on a meridian, but must gradually decrease from thence to 0 at the poles.

The following table exhibits the length in geographical miles, of a degree of longitude for every degree of latitude.

Deg. Lat.	Geograp. Miles.	Deg Lat.	Geograp. Miles.	Deg. Lat.	Geograp. Miles.
0	60,00	31	51,43	61	29,09
1	59,99	32	50,88	62	28,17
2	59 96	33	50,32	63	27,24
3	59,92	34	49,74	64	26,30
4	59,85	35	49,15	65	25,36
5	59,77	36	48,54	66	24,41
6	59,67	37	47,92	67	23,44
7	59,56	38	47,28	68	22,48
8	59,42	39	46,63	69	21,50
9	59,26	40	45,96	70	20,52
10	59,09	41	45,28	71	19,53
11	58,90	42	44,59	72	18,54
12	58,69	43	43,88	73	17,54
13	58,46	44	43,16	74	16,53
14	58,22	45	42,43	75	15,53
15	57,95	46	41,68	76	14,52
16	57,67	47	40,92	77	13,50
17	57,38	48	40,15	78	12,47
18	57,06	49	39,36	79	11,45
19	56,73	50	31,57	80	10,42
20	56,38	51	38,76	81	9,38
21	56,02	52	36,91	82	8,34
22	55,63	53	36,11	83	7,31
23	55,23	54	35,27	84	6,27
24	54,81	55	34,41	85	5,23
25	54,38	56	33,55	86	4,18
26	53,93	57	32,68	87	3,14
27	53,46	58	31,79	88	2,09
28	52,97	59	30,90	89	1,04
29	52,47	60	30,00	90	0,00
30	51,96				

To use this table, divide the assumed degree into sixty parts by a diagonal line, fig. 9: look for the number of miles answering to the degree of lat. 49, which is 39, 36, say $39\frac{1}{2}$, which take off the scale, fig. 9, at *a*, and set off four times from C towards A, and the same from C towards B. The top meridian is 56° of lat. opposite which, in the table, is 33, 55, say $33\frac{1}{2}$, which take from the scale, fig. 9, at *b*, and set off four times from D towards E, and the same from D towards F. Draw the meridian lines to the corresponding divisions at top and bottom, of which 0 0 is the meridian of London.

Second. When the meridians and parallels are curved lines.

To project a map of Europe by this method.—Draw a base line GH, fig. 10, in the middle of which erect the perpendicular JP, and assume any distance for 10° of latitude.

Europe extends from 36° to 72° N. lat.

Let the point J be 30°, from which set off six of the assumed distances to P, which will be the N. pole.

Number the distances 40, 50, 60, &c.

On the centre P, describe arcs passing through the points of division on the line JP, which will be parallels of latitude.

Divide the space assumed for 10° of lat. into 60 parts by a diagonal line, fig. 11.

Look into the foregoing table for the number of miles answering to 30°, which is 51,96, say 52, which take from the scale, fig. 11, at *b*.

Set this distance off on the arc 30, 30, from the centre line JP both ways.

Do the same for 40°, 50°, 60°, &c.

Through the corresponding divisions, on all the arcs, draw curve lines; which will represent the meridians.

Number the degrees of lat. and lon., which will complete the diagram.

MARANTA, *Indian arrow-root*, a genus of the monogynia order, in the monandria class of plants, and in the natural method ranking under the eighth order, scitamineæ. The corolla is ringent and quinquefid, with two segments alternately patent. There are five species, all of them herbaceous perennial exotics of the Indies, kept here in hot-houses for curiosity: they have thick, knotty, creeping roots, crowned with long, broad, arundinaceous leaves, ending in points, and upright stalks, half a yard high, terminated by bunches of monopetalous, ringent, five-parted flowers. The root of the galanga is used by the Indians to extract the virus communicated by their poisoned arrows: whence it has derived its name of arrow-root. The arundinacea, or starch plant, rises to two feet, has broad pointed leaves, small white flowers, and one seed. It is cultivated in gardens and in provision grounds in the West Indies; and the starch is obtained from it by the following process: The roots when a year old are dug up, well washed in water, and then beaten in large deep wooden mortars to a pulp. This is thrown into a large tub of clean water. The whole is then well stirred, and the fibrous part wrung out by the hands, and thrown away. The milky liquor being passed through a hair-sieve, or coarse cloth, is suffered to settle, and the clear water is drained off. At the bottom of the vessel is a white mass, which is again mixed with clean water, and drained: lastly, the mass is dried on sheets in the sun, and is pure starch.

MARATTIA, a genus of the cryptogamia filices. The capsules are oval, gaping longitudinally at top, with several cells on each side. There are three foreign species.

MARBLE, in natural history, a genus of fossils, composed chiefly of lime; being bright and beautiful stones, moderately hard, not giving fire with steel, fermenting with, and soluble in, acid menstrua, and calcining in a slight fire. The word comes from the French marbre, and that from the Latin marmor, of the Greek μαρμαιρειν, to shine, or glitter. See LIME.

The colours by which marbles are distinguished are almost innumerable; but the most remarkable are, 1. The black marble of Flanders. 2. Plain yellow. 3. Yellow with some white veins. 4. Yellow with black dendrites. 5. Yellow with brown figures resembling ruins. 6. Black and yellow. 7. Black and white. 8. Pale yellow, with spots of a blackish-grey colour. 9. Yellow, white, and red. 10. Pale yellow. 11. Olive-colour, with deeper-coloured cross lines, and dendrites. 12. Brownish-red. 13. Flesh coloured and yellow. 14. Common red marble. 15. Crimson, white, and grey. 16. Reddish-brown lumps, on a whitish ground. 17. Blueish-grey. 18. Snowy-white.

The finest solid modern marbles are those of Italy, Blankenburg, France, and Flanders. It has also been lately discovered that very fine marble is contained in some of the western islands of Scotland. Those of Germany, Norway and Sweden, are of an inferior kind, being mixed with a kind of scaly limestone; and even several of those above-mentioned are partly mixed with this substance, though in an inferior degree. Cronstedt, however, mentions a new quarry of white marble in Sweden, which, from the specimens he had seen, promised to be excellent.

The specific gravity of marble is from

2700 to 2800; that of Carriera, a very fine Indian marble, is 2717. Black marble owes its colour to a slight mixture of iron. Mr. Bayen found some which contained five per cent. of the metal; notwithstanding which the lime prepared from it was white, but in time it acquired an ochry, or reddish-yellow colour.

MARBLE, *polishing of*, is performed by first rubbing it well with a freestone, or sand, till the strokes of the axe are worn off, then with pumice-stone, and afterwards with emery.

MARBLING, in general, the painting any thing with veins and clouds, so as to represent those of marble.

Marbling of books or paper is performed thus: Dissolve four ounces of gum-arabic into two quarts of fair water; then provide several colours mixed with water in pots or shells, and with pencils peculiar to each colour, sprinkle them by way of intermixture upon the gum-water, which must be put into a trough, or some broad vessel; then with a stick curl them, or draw them out in streaks, to as much variety as may be done. Having done this, hold your book or books close together, and only dip the edges in, on the top of the water and colours, very lightly; which done, take them off, and the plain impression of the colours in mixture will be upon the leaves; doing as well the ends as the front of the book in the like manner.

Marbling books on the covers is performed by forming clouds with aquafortis, or spirit of vitriol mixed with ink, and afterwards glazing the covers.

MARCGRAVIA, a genus of the polyandria monogynia class of plants, the corolla whereof consists of a single petal, of a conico-oval figure; and its fruit is a globose berry, with a single cell, containing a great number of very small seeds. There is one species, a shrub of the West Indies.

MARCHANTIA, a genus of the cryptogamia class of plants, the corolla of which is monopetalous, turbinated, and shorter than the cup; in the lower cavity of which there are contained several naked seeds, of a roundish but compressed figure. There are seven species, five of them British.

MARCIONITES, christians in the second century, thus denominated from their leader Marcion, who maintained that there were two principles or gods, a good and a bad one.

MARCOSIANS, a sect of christians in the second century, so called from their leader Marcus, who represented the supreme God as consisting not of a trinity, but a quaternity, viz. the ineffable, silence, the father, and truth.

MARE. See EQUUS.

MARGARITERIA, a genus of the dioecia octandria class and order. The male calyx is four-toothed; corolla four-petalled. Female calyx and corolla as above; styles four or five. There is one species, a native of Surinam.

MARICA, a genus of the trigynia monogynia class and order. The calyx is six-parted; stigma petal-form, trifid; capsule three-celled, inferior. There is one species, a fleshy bulb of Guiana.

MARILLA, a genus of the class and order polyandria monogynia. The calyx is five-leaved; corolla five-petalled; capsule four-celled, many-seeded; stigma simple. There is one species, a native of the West Indies.

MARK, *knights of St.*, an order of knighthood in the republic of Venice, under the protection of St. Mark the evangelist. The arms of the order are, gules, a lion winged or, with this device, "Pax tibi Marce evangelista." This order is never conferred but on those who have done signal service to the commonwealth.

MARK, or MARC, also denotes a weight used in several states of Europe, and for several commodities, especially gold and silver. In France, the mark is divided into 8 oz. or 64 drachms, or 192 derniers or pennyweights, or 160 esterlines, or 300 mailles, or 640 felins, or 4608 grains. In Holland the mark-weight is also called troy-weight, and is equal to that of France. When gold and silver are sold by the mark, it is divided into 24 caracts.

MARK is also used among us for a money of account, and in some other countries for a coin. The English mark is two-thirds of a pound sterling, or 13*s.* 4*d.* and the Scotch mark is of equal value in Scotch money of account. The mark-lubs, or lubeck-mark, used at Hamburgh, is also a money of account, equal to one-third of the rix-dollar, or to the French livre: each mark is divided into 16 sols-lubs. Mark-lubs is also a Danish coin equal to 16 sols-lubs. Mark is also a copper and silver coin in Sweden.

MARKET. A market is less than a fair, and is commonly held once or twice a week. According to Bracton, one market ought to be distant from all others at least six miles and a half and a third of a half: but no market is to be kept within seven miles of the city of London; but all butchers, victuallers, &c. may hire stalls and standings in the flesh-markets there, and sell meat and other provisions, four days in a week. Every person who has a market is entitled to receive toll for the things sold in it; and, by antient custom, for things standing in the market, though nothing be sold: but by keeping a market in any other manner than it is granted, or extorting of tolls or fees where none are due, they may be forfeited.

In London every shop in which goods are exposed publicly to sale, is market overt for such things only as the owner professes to trade in: though if the sale is in a warehouse, and not publicly in the shop, the property is not altered. But if goods are stolen from one, and sold out of the market overt, the property is not altered, and the owner may take them wherever he finds them. 5 Rep. 83.

If a man buy his own goods in a market, the contract shall not bind him, unless the property had been previously altered by a former sale.

MARLE. A mixture of carbonat of lime and clay, in which the carbonat considerably exceeds the other ingredient, is called marle. Its structure is earthy. Opaque, sometimes in powder. Specific gravity from 1.6 to 2.877. Colour usually grey, often tinged with other colours. Effervesces with acids. Some marles crumble into powder when exposed to the air; others retain their hardness for many years. Marles may be divided into two varieties: 1. Those which contain more silica than alumina. 2. Those which contain more alumina than silica. Mr. Kirwan has called the first of these siliceous, the second argillaceous marles. Attention should be paid to this distinction when marles are used as a manure.

MARLE, *bituminous*, is found in different parts of Germany. Colour greyish or brownish-black. Found massive. Shistose. Plates flat or waved. Opaque. Feels soft. Easily broken. Moderately heavy. Effervesces with acids. Burns before the blowpipe, leaving black scoriæ.

MARLINS, in artillery, are tarred white skains, or long wreaths or lines of untwisted hemp, dipped in pitch or tar, with which cables and other ropes are wrapped round, to prevent their fretting and rubbing in the blocks or pulleys through which they pass. The same serves in artillery upon ropes used for rigging gins, usually put up in small parcels called skains.

MARMOTTE. See MUS.

MARQUE. See LETTERS *of Marque*.

MARQUETRY, or INLAID WORK, is a curious work composed of several fine hard pieces of wood, of various colours, fastened in thin slices on a ground, and sometimes enriched with other matters, as silver, brass, tortoise-shell, and ivory; with these assistances the art is now capable of imitating any thing, whence it is by some called the art of painting in wood.

The ground on which the pieces are to be arranged and glued is usually of well-dried oak or deal; and is composed of several pieces glued together, to prevent its warping. The wood to be used in marquetry is reduced into leaves of the thickness of a line, or the 12th part of an inch, and is either of its natural colour, or stained, or made black to form the shades by other methods: this some perform by putting it in sand heated very hot over the fire; others by steeping it in lime-water and sublimate; and others in oil of sulphur. The wood being of the proper colours, the contours of the pieces are formed according to the parts of the design they are to represent: this is the most difficult part of marquetry, and that which requires the most patience and attention.

The two chief instruments used in this work are a saw and a wooden vice, which has one of its chaps fixed, and the other moveable; which is open and shut by the foot, by means of a cord fastened to a treadle.

MARQUIS, a title of honour, next in dignity to that of duke, first given to those who commanded the marches, that is, the borders and frontiers of countries.

Marquises were not known in England till the reign of king Richard II. and the year 1337.

MARRIAGE, a contract, both civil and religious, between a man and a woman.

Taking marriage in the light of a civil contract, the law treats it as it does all other contracts: allowing it to be good and valid in all cases where the parties, at the time of making it, were, in the first place, willing to contract; secondly, able to contract; and, lastly, actually did contract in the proper forms and solemnities required by law. 1 Black. 433.

By several statutes a penalty of 100*l.* is inflicted for marrying any persons without banns or licence. But by 25 G. II. c. 33, if any person shall solemnize matrimony without banns or licence obtained from some persons having authority to grant the same, or in any other place than a church or chapel where banns have been usually published, unless by special licence from the archbishop of Canterbury, he shall be guilty of felony, and transported for 14 years, and the marriage shall be void.

MARROW. See ANATOMY.

MARRUBIUM, *white horehound*, a genus of the gymnospermia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillatæ. The calyx is salver-shaped, rigid, and ten-striated; the upper lip of the corolla bifid, linear, and straight. There are 11 species, the most remarkable of which is the vulgare, a native of Britain, growing naturally in waste places, and by way-sides near towns and villages, but not common. It has a strong and somewhat musky smell, and bitter taste. It is reputed attenuant and resolvent; an infusion of the leaves in water, sweetened with honey, is recommended in asthmatic and phthisical complaints, and most other diseases of the breast and lungs.

MARS, in astronomy, one of the superior planets, moving round the sun in an orbit between those of the earth and Jupiter. See ASTRONOMY.

MARSHAL, in its primary signification, means an officer who has the command or care of horses; but it is now applied to officers who have very different employments, as earl-marshal, knight-marshal, or marshal of the king's house, &c.

MARSHAL *of the king's bench*, an officer who has the custody of the king's bench prison in Southwark. This officer is obliged to give his attendance, and to take into his custody all persons committed by that court.

MARSHAL *of the exchequer*, an officer to whom that court commits the king's debtors.

MARSHALLEA, a genus of the class and order syngenesia polygamia æqualis, little known.

MARSHALLING a coat, in heraldry, is the disposal of several coats of arms belonging to distinct families, in one and the same escutcheon or shield, together with their ornaments, parts, and appurtenances.

MARSHALSEA-COURT, is a court of record, originally instituted to hear and determine causes between the servants of the king's household and others within the verge of the court, and has jurisdiction of things within the verge of the court, and of pleas of trespass, where either party is of the king's family; and of all other actions personal, wherein both parties are the king's servants; but the court has also power to try all personal actions, as debt, trespass, slander, trover, action on the case, &c. between party and party, the liberty whereof extends 12 miles about Whitehall.

The judges of this court are the steward of the king's household, and high-marshal for the time being; the steward of the court, or his deputy, is generally an eminent counsel.

If a cause of importance is brought in this court, it is generally removed into the court of king's bench or common pleas by a habeas corpus cum causa.

MARSILEA, a genus of the cryptogamia class of plants, without any corolla or cup: the antheræ are four, and placed on an obtusely conic body; the fruit is of a roundish figure, consisting of four cells, in each of which are contained several roundish seeds. There are three species.

Under this genus are comprehended the salvinia of Micheli, and pilularia of Dillenius.

MARTIAL LAW, is the law of war, which entirely depends on the arbitrary power of the prince, or of those to whom he has delegated it. For though the king can make no laws in time of peace without the consent of parliament, yet in time of war he uses an absolute power over the army.

MARTIN. See HIRUNDO, and MUSTELA.

MARTLETS, in heraldry, little birds represented without feet, and used as a difference or mark of distinction for younger brothers.

MARTNETS, in a ship, small lines fastened to the leech of a sail, reeved through a block on the topmast-head, and coming down by the mast to the deck. Their use is to bring the leech of the sail close to the yard to be furled.

MARTYNIA, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 10th order, personatæ. The calyx is quinquefid; the corolla ringent, the capsule ligneous, covered with a bark, with a hooked beak, trilocular, and bivalved. There are 60 species, tender, herbaceous, flowery, plants of South America.

MARYGOLD. See CALENDULE; and for MARSH-MARYGOLD, see CALTHA.

MASON, a person employed under the direction of an architect, in the raising of a stone building. See ARCHITECTURE.

MASSETER. See ANATOMY.

MASSICOT, a name given to the yellow oxide of lead, as minium is applied to the red oxide.

MASSONIA, a genus of the class and order hexandria monogynia. The corolla is inferior, with 6-parted border; filaments on the neck of the tube; capsule 3-winged, 3-celled, many-seeded. There are four species, bulbs of the Cape.

MAST, in naval architecture, a large timber in a ship, for sustaining the yards, sails, &c.

In large vessels there are four masts, viz. the mainmast, foremast, mizenmast, and bowsprit. The mainmast is the principal one, standing in the middle of the ship: its length, according to some, should be $2\frac{1}{2}$ that of the midship-beam. Others give the following rule for finding its length, viz. multiply the breadth of the ship, in feet, by 24; from the product cut off the last figure towards the right hand, and the rest will be the length required. Thus suppose the length of the midship-beam was 30 feet; then $30 \times 24 = 720$, from which cutting off the last figure, there remains 72 feet for the length of the mainmast. And as for the thickness of the mainmast, it is usual to allow an inch to every yard in length. See SHIP-BUILDING.

MASTER AND SERVANT. In London and other places the mode of hiring is by what is commonly called a month's warning or a month's wages: that is, the parties agree to separate on either of them giving to the other a month's notice for that purpose; or, in lieu thereof, the party requiring the separation to pay, or give up, a month's wages. But if the hiring of a servant is general, without any particular time specified, it will be construed to be a hiring for a year certain; and in this case if the servant departs before the year, he forfeits all his wages. Noy, Max. 107. And where a servant is hired for one year certain, and so from year to year as long as both parties shall agree, and the servant enters upon a second year, he must serve out that year, and is not merely a servant at will after the first year. If a woman-servant marries she must nevertheless serve out her term; and her husband cannot take her out of her master's service.

If a servant is disabled in his master's service by an injury received through another's default, the master may recover damages for loss of his service. And also a master may not only maintain an action against any one who entices away his servant, but also against the servant; and if without any enticement a servant leaves his master without just cause, an action will lie against another who retains him with a knowledge of such departure.

A master has a just right to expect and exact fidelity and obedience in all his lawful commands; and to enforce this he may correct his servant in a reasonable manner, but this correction must be to enforce the just and lawful commands of the master. Bul. N. P. 18.

In defence of his master a servant may justify assaulting another; and though death should ensue it is not murder, in case of any unlawful attack upon his master's person or property.

Acts of the servant are, in many instances, deemed acts of the master; for as it is by indulgence of law that he can delegate the power of acting for him to another, it is just he should answer for such substitute, and that his acts being pursuant to the authority given him, should be deemed the acts of his master. 4 Bac. Abr. 583. If a servant commits an act of trespass by command or encouragement of his master, the master will be answerable; but in so doing his servant is not excused, as he is bound to obey the master in such things only as are honest and lawful.

If a servant of an innkeeper robs his master's guest, the master is bound to make good the loss. Also, if a waiter at an inn sells a man bad wine, by which his health is impaired, an action will go against the master: for his permitting him to sell it to any person is deemed an implied general command. 1 Black. 430. In like manner if a servant is frequently permitted to do a thing by the tacit consent of his master, the master will be liable, as such permission is equivalent to a general command.

If a servant is usually sent upon trust with any tradesman, and he takes goods in the name of his master upon his own account, the master must pay for them: and so likewise if he is sent sometimes on trust, and other times with money; for it is not possible for the tradesman to know when he comes by the order of his master, and when by his own authority, or when with and without money. Str. 506. But if a man usually deals with his tradesmen himself, or constantly pays them ready money, he is not answerable for what his servant may take up in his name; for in this case there is not, as in the other, any implied order to trust him. Or if the master never had any personal dealings with the tradesman, but the contracts have always been between the servant and the tradesman, and the master has regularly given his se vant money for payment of every thing had on his account, the master shall not be charged. Esp. N. P. 115. Or if a person forbids his tradesmen to trust his servant on his account, and he continues to purchase upon credit, he is not liable. The act of a servant, though he has quitted his master's service, has been held to be binding upon the master, by reason of the former credit given him on his master's account, and it not being known to the party trusting that he was discharged. 4 Bac. Abr. 586.

The master is also answerable for any injury arising by the fault or neglect of his servant when executing his master's business, 6 T. R. 659: but if there is no neglect or default in the servant the master is not liable. Esp. Rep. 533.

If a smith's servant lames a horse whilst shoeing him, or the servant of a surgeon makes a wound worse, in both these cases an action for damages will lie against the master, and not against the servant. But the damage must be done while the servant is actually employed in his master's service, otherwise he is liable to answer for his own misbehaviour or neglect.

A master is likewise chargeable if his servant casts any dirt, &c. out of the house into the common street; and so for any other nuisance occasioned by his servants, to the damage or annoyance of any individual, or the common nuisance of his majesty's people. Lord Raym. 264.

A servant is not answerable to his master for any loss which may happen without his wilful neglect; but if he is guilty of fraud or gross negligence, an action will lie against him by his master.

A master is not liable in trespass for the wilful act of his servant; as by driving his master's carriage against another, done without the direction or assent of his master, no person being in the carriage when the act was done. But he is liable to answer for any damage arising to another from the negligence or unskilfulness of his servant acting in his employ. M'Manus v. Crickitt, Mich. 41 G. III.

Master of arts, is the first degree taken up in foreign universities, and for the most part in those of Scotland, but the second in Oxford and Cambridge; candidates not being admitted to it till they have studied seven years in the university.

Master in chancery. The masters in chancery are assistants to the lord chancellor and master of the rolls; of these there are some ordinary, and others extraordinary: the masters in ordinary are 12 in number, some of whom sit in court every day during the term, and have referred to them interlocutory orders for stating accounts, and computing damages and the like; and they also administer oaths, take affidavits, and acknowledgments of deeds and recognizances. The masters-extraordinary are appointed to act in the country, in the several counties of England, beyond 10 miles distant from London; by taking affidavits, recognizances, acknowledgments of deeds, &c. for the ease of the suitors of the court.

Master of the faculties, an officer under the archbishop of Canterbury, who grants licences and dispensations.

Master of the horse, a great officer of the crown, who orders all matters relating to the king's stables, races, breed of horses, and commands the equerries and all the other officers and tradesmen employed in the king's stables. His coaches, horses, and attendants, are the king's, and bear the king's arms and livery.

Master of the ordnance, a great officer, who has the chief command of the king's ordnance and artillery.

Master of the rolls, is an assistant to the lord chancellor of England in the high court of chancery; and in his absence hears causes there, and gives orders. His salary is 1200*l.* per annum.

Master of a ship, the same with captain in a merchantman; but in a king's ship he is an officer who inspects the provisions and stores, and acquaints the captain with what is not good, takes particular care of the rigging and of the ballast, and gives directions for stowing the hold; he navigates the ship under the directions of his superior officer; sees that the log and log-book are duly kept; observes the appearance of coasts; and notes down in his journal any new shoals or rocks under water, with their bearing and depth of water, &c.

Master at arms, in a king's ship, an officer who daily, by turns, as the captain appoints, is to exercise the petty officers and ship's company; to place and relieve sentinels; to see the candles and fire put out according to the captain's orders; to take care the small arms are kept in good order, and to observe the directions of the lieutenant at arms.

MASK, in field fortification: it sometimes happens that a ditch or fosse must be dug in an exposed situation; in this case it will be absolutely necessary for the artificers and workmen to get under cover by means of masking themselves in such a manner as to answer the double purpose of executing their immediate object, and of deceiving the enemy with respect to the real spot they occupy.

To effect the latter purpose several masks must be hastily thrown up, whilst the men are employed behind one; by which means the enemy will either mistake the real point, or be induced to pour his fire in several directions, and thus weaken its effect.

A mask is generally six feet high. Bags made of wad or wool are too expensive on these occasions; nor are gabions, stuffed with fascines, seven or eight feet high, to be preferred; for if the fascines are tied together they will leave spaces between them in the gabions: and if they are not bound together, they will be so open at top as to admit shot, &c.

In order to obviate these inconveniences the following method has been proposed: Place two chandeliers, each seven feet high and two broad, between the uprights, after which fill up the vacant spaces with fascines nine feet high, upon six inches diameter. One toise and a half of epaulement will require two chandeliers and 60 fascines to mask it.

The engineer, or artillery officer, places himself behind this mask, and draws his plan.

As you must necessarily have earth, &c. to complete your work, these articles may be brought in shovels, sacks, or baskets; and if the quarter whence you draw them should be exposed to the enemy's fire, cover that line, as well as the line of communication, between the trenches, or the parallels, with a mask.

If you cannot procure earth and fascines, make use of sacks stuffed with wool, &c. and let their diameters be three feet, and their length likewise three; and let the outside be frequently wetted to prevent them from catching fire.

MASTOIDES. See Anatomy.

MATCH, a kind of rope slightly twisted, and prepared to retain fire for the uses of artillery, mines, fireworks, &c. It is made of hempen tow, spun on the wheel like cord, but very slack; and is composed of three twists, which are afterwards again covered with tow, so that the twists do not appear: lastly, it is boiled in the lees of old wines. This, when once lighted at the end, burns on gradually and regularly, without ever going out, till the whole is consumed: the hardest and driest match is generally the best.

Match, *quick*, used in artillery, is made of three cotton strands drawn into lengths, and put into a kettle just covered with white-wine vinegar, and then a quantity of saltpetre and mealed powder is put into it, and boiled till well mixed. Others put only saltpetre into water, and after that take it out hot, and lay it into a trough with some mealed powder, moistened with some spirits of wine, thoroughly wrought into the cotton by rolling it backwards and forwards with the hands; and when this is done they are taken out separately, drawn through mealed powder, and dried upon a line.

MATERIA MEDICA. "The materia medica (says Dr. Darwin) includes all those substances which may contribute to the restoration of health." If, however, medicine be defined the art of *preventing*, as well as of curing, diseases, the science of which we are now to treat ought, by consequence, to comprehend the preservatives of living existence, as well as the restoratives of healthy action. Instead, therefore, of restricting this article to the mere enumeration and discussion of drugs, we shall, in the first place, introduce some general remarks on those substances which are employed as articles of diet or food.

PART I.

DIETETICS.

Organic life appears to be influenced and supported by two leading principles: 1st, fibrous excitation; and, 2dly, the substitution of nutritious particles, in place of those which are constantly dissipated or abraded. The power by which this last object is effected has been denominated by the author of Zoonomia, animal appetency. The principal and prime organs by which it is exerted, or the media through which new matter is originally communicated, are those which are termed the digestive and assimilating: it has, however, recently been conjectured that the organs of digestion are not the sole organs of nutrition, but that both the external surface of the body, and likewise the lungs, are media for the admission into the system of proper nutritive matter. Accordingly we find the class nutrientia, in the materia medica of the author just quoted, to comprehend not merely those substances which are received into the stomach as food, but also the matter which is taken into the lungs in the act of respiration, as likewise air, water, and other substances that may be applied naturally or artificially to the outer skin. To enquire into the grounds upon which this doctrine is established, that the lungs, the stomach, and the surface of the body, each affords instruments in common of actual nutrition, does not fall within the province of the present article. See PHYSIOLOGY. It will be proper here to confine ourselves to the general consideration of what is usually denominated animal and vegetable diet.

OF ANIMAL FOOD.

That man is designed by nature for a mixture of animal and vegetable food, is obvious from the structure of his organs, both of mastication and digestion. That the flesh of animals contains more nutritive matter, and that it stimulates the absorbent and secerning vessels more powerfully, than vegetable aliment, is demonstrated by the superior warmth and strength which in a state of health we experience after a meal of flesh than of vegetables: of the former (animal flesh), that, in general, which is of the darkest colour, contains more nutritive matter, and stimulates our vessels with more energy, than the white kinds: indeed the flesh of those animals which are carnivorous, or which live entirely on animal food, seldom enters into the diet of European, or civilized nations. The greater stimulating virtue of this kind of food has been attributed to the greater quantity which it has been suppo·ed to contain of volatile alkali. Dr. Darwin, however, properly questions whether it is not rather the elements only of this principle that are contained even in the strongest dark-coloured animal flesh.

Next in strength to the flesh of carnivorous animals ought to rank that of those animals when killed after full growth, the young of which afford a softer, whiter, more digestible, but less nutritious, food, such as the sheep, the bullock, the hog, and likewise several of the shell-fish, as lobsters, crabs, muscles, &c. in which class may likewise be enumerated several fish that are destitute of scales or shells, as eel, barbolt, tench, smelt, turtle, turbot. Of the fowl kind the bustard, woodpecker, starling, sparrow, goose, duck, and lapwing, ought to be arranged in this second class. These, with a due mixture of vegetable aliment, constitute the best kinds of food for healthy and athletic individuals, whose digestion is powerful, and who have a firm fibre.

The flesh of young animals, as of lamb, veal, and sucking pigs, afford a less stimulating and nutritious, but more digestible food: these meats are consequently most congenial to persons of less muscular energy, who have more feeble powers of digestion, and who accustom themselves to but little exercise: they are adapted to the hypochondriac, and should be principally used as aliment by individuals who are disposed to those kind of affections which have received the vulgar and indiscriminate appellation of scorbutic.

A still milder, but, in the same proportion, less nutritive food, is furnished by the white meats, such as the domestic fowl, partridge, pheasant, and their eggs, with oysters and young lobsters. These, from their bland and unacrimonious nature, are generally allowed to convalescents from acute diseases: they are peculiarly suitable to very weak stomachs, and ought in general to form the first articles in the diet of females after childbirth. The major part of the river fish which have scales, as pike, perch, and gudgeon, are possessed of very inferior nutritive faculty.

OF MILK AND ITS PRODUCTS.

Milk partakes of the properties of both animal and vegetable aliment: it may be separated by rest or by agitation into cream, buttermilk, whey, and curd. The cream is easier of digestion by the adult stomach, on account of its containing less of the caseous, or cheesy part; it is likewise on this account more nutritive. Butter contains still more nutriment, and is likewise, if not taken to excess, exceedingly easy of digestion, and is by no means calculated to generate unpleasant humours in the body. If given without any separation of its principles by artificial preparation, it might be admitted into the diet of infancy with much greater propriety than other articles which are employed with less apprehension of injury. Buttermilk is agreeable, bland, and gently nutritive. Whey is the least nutritious, and most easy of digestion. It is on this account ordered with the utmost propriety to those invalids whose constitutions have been rendered too irritable to bear the stimulus of more solid and nutritive aliment. Cheese is of various kinds, arising principally from the greater or less quantity of cream that it contains. Those cheeses which are broken to pieces in the mouth with most readiness are, for the most part, most easy of digestion, and most nutritive. Many kinds of cheeses are a considerable time in undergoing chemical change in the stomach; and on this account, although difficult of digestion, do not disagree with weak stomachs. Dr. Darwin observes that he has seen toasted cheese vomited up a whole day after it was eaten, without having become perceptibly altered, or given any uneasiness to the patient.

New cow's-milk is the food of infants, and is by far the best substitute for the milk of the mother, if this last be not afforded in sufficient quantity or quality by the parent, which, however, is seldom the case. The stomachs of children abound with acidity; and milk, which is always curdled before it is assimilated, is consequently digested with more facility in the earlier than in the more advanced periods of life. It is on this account likewise that certain vegetable substances, which have a great tendency to acidity, are exceedingly injurious to the infantile stomach. See the article INFANCY.

OF VEGETABLE FOOD.

The seeds, roots, leaves, and fruits, of plants, particularly the two former, constitute a very material part of the food of mankind. According to the opinion of Dr. Cullen, and other physiologists, the quantity of actual nourishment that these contain, is in proportion to the quantity of sugar that they can be made to produce; it is imagined that the mucilage which the farinaceous seeds contain, is changed in the granary to starch; and that this starch, in the processes to which the seeds are afterwards subjected, or by digestion in the stomach, is at length converted into saccharine principle. See PHYSIOLOGY. The farinaceous seeds are wheat, barley, oats, rye, millet, maize or Indian corn, &c. The roots of this class are the sugar-root, the common carrot, beet, and polypody. Those with less of the saccharine principle, and which afford a tender farina, are the turnip-rooted cabbage, the parsnip, parsley root, asparagus, turnips, potatoes, &c.; all of which, if less nutritive, are better suited to weakly organs of digestion than those in which the sugar is more abundant.

Other vegetables contain oil, sugar, mucilage, or acid, in various proportions, diluted with much water: these are but slightly nutrimental; and are, for the most part, injurious to delicate stomachs especially, unless taken with moderation; these are the apple, pear, plum, apricot, nectarine, peach, strawberry, grape, orange, melon, cucumber, dried figs, raisins, and a great variety of other roots, seeds, leaves, and fruits. Of these it may be observed generally, that those which are cold, watery, and sweet, are most calculated to prove indigestible, and consequently injurious.

DIFFERENT METHODS OF DRESSING VICTUALS.

Various modes of preparing and dressing both animal and vegetable articles of food have been contrived, in order to render them more palatable, and better adapted to the stomach. By boiling, animal flesh is, in some measure, deprived of its nourishing juice, which is with more or less facility given out to, and incorporated with, the broth: this last then contains the most nutritious part of the meat; but unless stronger than is ordinarily used, it is too diluted to admit of an easy digestion. Broths likewise have a remarkable tendency to acidity, particularly when made from the flesh of young animals, as of lamb and veal; and on this account also are much less congenial to weak stomachs than is generally imagined. The various jellies, which contain the gelatinous and nutritive, to the exclusion of the fibrous part of animal flesh, are in general much more suitable to the invalid and the convalescent than either broths or soups. Perhaps the most eligible mode of preparing animal food is by the process called stewing; for by this process its nutritious and substantive parts are concentrated and preserved. It is scarcely necessary to observe that the gravy of boiled meat contains its nutritive parts in a state of concentration; it is digested with facility; and gravy is therefore the best mode of giving animal food to very young infants.

Roasting preserves the nutritive part of flesh from dissipation in a greater degree than boiling: and it has been asserted by an observant author (Dr. Willich) that "one pound of roast meat is, in real nourishment, equal to two or three pounds of boiled meat." It ought however to be noticed, that the fat of meat treated in this way has undergone some degree of chemical decomposition from its exposure to heat, and is in consequence more oppressive to delicate stomachs, and generally less salutary, than that of boiled flesh. Both baking and frying are upon similar principles improper methods of preparing animal food. Smoked meats, as prepared hams, are hard of digestion. They should only be taken in small quantities, and rather as condiment than food.

The art of cookery, as applied to vegetable substances, is principally useful in destroying the native acrimony, and rendering the texture softer of some, and by converting the acerb juices of others into saccharine matter. The boiling of cabbage, of asparagus, &c. are examples of the one, the baking of unripe pears is an instance of the other. The above are all chemical processes; they are too familiar to need description.

Another mode by which the nourishment of mankind is facilitated, is the mechanic art of grinding farinaceous seeds into powder; and, in some instances, exposing them afterwards to a fermenting process, as in the making of bread, and then to the action of fire by baking or boiling. The mill-stones, by which the process of grinding is effected, have been quaintly termed the artificial teeth of society. It has been suggested by Dr. Darwin, that "some soft kinds of wood, especially when they have undergone a kind of fermentation, and become looser, might, by being subjected to the action of the mill-stones, be probably used as food in the times of famine. Nor is it improbable," continues our ingenious speculator, "that hay which has been kept in stacks, so as to undergo the saccharine process, may be so managed by grinding and by fermentation with yeast, like bread, as to serve in part for the sustenance of mankind in times of great scarcity. Dr. Priestley gave to a cow, for some time, a strong infusion of hay in large quantities for drink, and found that she produced during this treatment above double the quantity of milk. Hence if bread cannot be made from ground hay, there is great reason to suspect that a nutritive beverage may be thus prepared, either in its saccharine state, or fermented into a kind of beer. In times of great scarcity there are other vegetables, which, though not in common use, would most probably afford wholesome nourishment, either by boiling them, or drying and grinding them, or by both those processes in succession. Of these perhaps are the tops and barks of all those vegetables which are armed with thorns or prickles, as gooseberry-trees, holly, gorse, and perhaps hawthorn. The inner bark of the elm-tree makes a kind of gruel; and the roots of fern, and probably very many other roots, as of grass and clover taken up in winter, might yield nourishment, either by boiling or baking, and separating the fibres from the pulp by beating them; or by getting only the starch from those which possess an acrid mucilage, as the white betony. And the alburnum of perhaps all trees, and especially of those which bleed in spring, might produce a saccharine and mucilaginous liquor, by boiling it in the winter or spring."

OF DRINK.

"Water," says Dr. Darwin, "must be considered as a part of our nutriment, because so much of it enters the composition of our fluids; and because vegetables are believed to draw almost the whole of their nourishment from this source." It may, however, be questioned whether pure elementary water taken into the stomach acts upon the system as a nutrimental matter in any other mode than by procuring the solution, and thus facilitating the assimilation, of solid aliment.

Water is the natural and proper drink of man. It is the basis of all other liquids; and the larger proportion of water that enters their composition, the more easily, in a state of health, and provided proper food has been taken, are the solution and digestion of such food effected.

This fluid, however, is never or seldom taken in a state of entire purity. Even in nature's laboratory it is invariably impregnated with foreign substances; and it is this admixture of extraneous matter which constitutes its varieties. Thus we have snow water, rain water, spring water, river water, and water from lakes, wells, and swamps, each possessing their individual characteristics.

Spring water is, in general, most free from impurities; it is, however, less suited for drink than the water of rivers, as it almost constantly contains calcareous, or saline ingredients. The calcareous earth dissolved in the water of many springs, has been supposed indeed by Dr. Darwin to contribute to our nourishment in the manner that lime proves useful in agriculture. This principle, however is not perhaps fully established; and we believe that too much stress has by theorists in general been laid on the specific qualities of water, as modifying both the bodily and intellectual character of individuals and nations. The cretinism and fatuity of the Alpine valleys were formerly attributed to the waters of these countries, but are now more commonly, and we believe more justly, referred to constitutional propensity, innutritious food, and a humid unhealthy atmosphere.

That water however possesses great varieties, according to the nature of the soil and situation of the place in which it is produced or contained, is undeniable; and we shall here extract part of what is observed on these varieties by an attentive and judicious observer.

"*Spring water*," says Dr. Willich, "originates partly from that of the sea, which has been changed into vapours by subterraneous heat, and partly from the atmosphere. As it is dissolved and purified in a variety of ways before it becomes visible to us, it is lighter and purer than other waters.

"*Well water.* Wells opened in a sandy soil are the purest. The more frequently a well is used, the better; for the longer water stands unmoved, the sooner it turns putrid.

"*River water* is more pure and wholesome if it flows over a sandy and stony soil, than if it passes over muddy beds, or through towns, villages, and forests: water is rendered foul by fish, amphibious animals, and plants.

"*Lake water* much resembles river water, but being less agitated it is more impure. The water which, in cases of necessity, is obtained from swamps and ditches, is the worst of all; because a great variety of impurities are there collected, which, in a stagnant and soft soil, readily putrify.

"*Rain water* is also impure, as it contains many saline and oily particles, soon putrefies, and principally consists of the joint exhalations of animals, vegetables, and minerals, of an immense number and variety of small insects and their eggs, seeds of plants, and the like. Rain water is particularly impure in places filled with many noxious vapours; such as marshy countries, and large manufacturing towns, where the fumes of metallic and other substances are mixed with rain. In high and elevated situations, at a distance from impure exhalations, if no strong winds blow, and after a gentle shower, rain water is then purest. In summer, however, on account of the copious exhalations, rain water is most objectionable.

"*Snow water* possesses the same properties as rain water, but is purer; both are soft, that is, without so many mineral and earthy particles as spring, well, and river waters. *Hail water*, being produced in the higher regions of the atmosphere, is still purer from its congelations. Lastly, *dew*, as it arises from the evaporation of various bodies of the vegetable and animal kingdoms, is more or less impure, according to the different regions and seasons."

On the different kinds and qualities of fermented and spirituous liquors, it does not fall within the compass of the present article to treat. They all consist of water as their base or vehicle, of more or less alcohol or ardent spirit according to their different degrees of strength, of sugar, and of the particular ingredient by which their nature is determined; such as the grape in wine, the apple and pear in cyder and perry, the malt and hop in beer, &c. &c. (See the respective articles in their alphabetical order.) It is only necessary here to observe, that, with few exceptions, fermented liquors, when immoderately taken, are more detrimental than elementary fluids, in proportion to the quantity that they contain of alcohol, or ardent spirit.

With respect to the China tea and the coffee-berry, which have lately come into such general use in this country, we believe them to be much less injurious to the animal economy than some theorists have been disposed to conjecture. In excess, however, and when indulged in as substitutes for, and, as is sometimes the case, almost to the exclusion of, nourishing diet, they are highly deleterious, as they tend to the induction of a morbidly irritable condition of the nervous system. It deserves to be remarked, that these stimuli do not, like alcohol, produce those formidable, and often irremediable, disorders, affections of the liver, dropsy, and apoplexy.

An enumeration of spices (which, like spirituous liquors, are used as articles of diet with too great freedom) will be found under the head Aromatics, in a subsequent section of this article.

PART II.

MEDICINALS.

We now proceed to the second division of our subject, or to the consideration of the materia medica in its more ordinary and limited signification.

Various divisions and modes of classification of those articles which are used in medicine, have been proposed and adopted by different authors. Some systematic writers arrange the articles of the materia medica according to their alphabetical order: others have taken for the basis of their arrangement the more sensible properties of drugs, as detected by the taste; thus reducing medicines to the different heads of bitterness, sweetness, astringency, acidity, &c.: while some have been regulated in their classification of medicinal articles, by their characters as objects in natural history. "As, however, the study of the materia medica is merely the study of the medicinal properties of certain substances, it is evident that the method of arranging them as they agree in producing effects on the living system is the one best calculated to fulfil all its objects." Murray.

Among the different plans of arrangement which have been framed on this principle, that adopted by Mr. Murray, in his late work on the materia medica, appears liable to the fewest objections. It is founded on the principle of Dr. Brown, "that medicines operate by stimulating the living fibre, or exciting it into motion." See the article Brunonian System. This proposition, however, was received and applied by its author in too unlimited a sense. In the first place, stimulation differs not merely in *degree*, but also in *kind*; or, in other words, one given medicine cannot by any regulation of its quantity be made to produce the same effects which result from the agency of another; some are more diffusible and transient, others more slow and permanent in their action; some affect the universal system in almost an equal degree, while the operation of others is more especially, and in some instances almost exclusively, directed to a certain part. They have all likewise properties peculiar to themselves.

But besides this general and very important modification of the Brunonian materia medica, it is necessary further to take into view, that medicines sometimes appear to display their agency even on the living body almost entirely upon chemical or mechanical principles: these last modes of operation, although less common and extensive than were supposed in the antient systems of medicine, must still be admitted as interfering with the universality, and opposing the unqualified assumption, of Dr. Brown, to which we have just alluded.

Guided by these views, Mr. Murray has adopted the general division of medicines under the four heads of *universal stimulants, local stimulants, chemical remedies*, and *mechanical remedies*, which are subdivided in the following manner:

TABLE OF CLASSIFICATION.

A. General stimulants.		
	a. Diffusible.	Narcotics.
		Antispasmodics.
	b. Permanent.	Tonics.
		Astringents.
B. Local stimulants.		Emetics.
		Cathartics.
		Emmenagogues.
		Diuretics.
		Diaphoretics.
		Expectorants.
		Sialagogues.
		Errhines.
		Epispastics.
C. Chemical remedies.		Refrigerants.
		Antacids.
		Lithontriptics.
		Escharotics.
D. Mechanical remedies.		Anthelmintics.
		Demulcents.
		Diluents.
		Emollients.

The objections which still lie against this, which we have chosen as the most perspicuous and comprehensive arrangement of medicines, will be urged, as we proceed to make some observations on their subdivisions, in the order of the above table.

The following, then, may be regarded, with some few exceptions, as an abridgment, or condensation, of the materia medica department of Mr. Murray's treatise. The names of the articles are adopted from the last edition, recently published, of the Parmacopœia collegii regii Medicorum Edinburgensis. In this edition the simples are principally indicated by the Linnæan names. We have added, however, the more customary titles, in order to obviate confusion.

OF NARCOTICS.

Medicines of this class had, previous to the time of Dr. Brown, been almost universally regarded as sedative, or depressing, even in their primary operation. By a bold, and, in some measure, legitimate generalization, our author proved that this kind of agency is, in the greater number of cases, merely of a secondary nature; and that the symptoms of depressed, or, more properly speaking, exhausted power, resulting from their administration, are consequent upon the faculty they possess of exciting, in a prompt and very extraordinary manner, the actions of the system. Thus opium, which is one of the most powerful of the narcotics, Dr. Brown maintained is, in the first instance, invariably stimulant; and the same virtue he attributes to the whole range of narcotic, or, as they were formerly characterized, sedative powers.

Although this conclusion is deduced from principles in the main correct, and in its application has been of abundant service in developing the laws of organic existence, it cannot, as we have above remarked, be admitted as universal, as the fact must be obvious to all who are not biassed by system, that "the sedative effects of narcotics are often disproportioned to their previous exciting operation, allowing even in such cases for its rapidity and little permanence." Murray. This fact then, in some measure, interferes with the correctness of our author's (Mr. Murray's) classification.

Narcotics are employed medicinally with different and opposite intentions. As stimulants they are given in various disorders of debility; in intermittent and continued fever, in gout, hysteria, epilepsy, dropsy, &c. As sedatives they are administered to allay pain and irritation, and are consequently largely administered in spasmodic and painful affections.

Alcohol, ardent spirit; spirit of wine. For the origin and preparation of this consult the article Alcohol. The stimulant effect of alcohol is generally known to be very powerful and diffusible; its exciting power is perhaps, in proportion to its sedative quality, greater than any of the other narcotics. Moderate excitement, with proportionate subsequent languor, results from a moderate dose of spirits. In larger quantities it occasions intoxication, delirium, stupor, coma, death.

Alcohol is used externally as a stimulant in muscular pains: it has lately been discovered to be an useful application in the cure of burns. Internally it is seldom employed in medicine without dilution; and then is rather administered as an auxiliary, or solvent of other ingredients.

Ether. Ethers bear some resemblance in their medicinal powers to alcohol: they are more diffusible, and less permanent in their operation. They are employed principally in asthma, hysteria, and other spasmodic affections. Their dose is from half a drachm to one or two drachms. Externally applied, sulphuric ether has been found to relieve spasmodic contraction of the muscles, and is often useful when applied to the temples in headache.

Camphora, laurus camphora (Lin.): habitat, Japan, India. Camphor is a proximate principle of vegetables; it is principally obtained from the laurus camphora of Japan.

In a moderate dose camphor is stimulant; in a larger quantity it invariably diminishes the force of the circulation, and induces sleep.

Camphor has been used as a stimulant in typhus, cynanche maligna, and other affections attended with debility and irritation; as a sedative in pneuomonia, rheumatism, &c. In mania it has been given as an anodyne. As an antispasmodic it is employed in asthma, St. Vitus's dance, and epilepsy. Its dose is from five to twenty grains. Externally, in combination with oil or liquid opium, camphor has been advantageously used in rheumatism, bruises, and other inflammatory affections.

Papaver somniferum, poppy. Europe, Asia. The concrete juice of the capsule of this plant is opium, which is chiefly imported from Egypt, Turkey, and the East Indies.

The effects of opium, as above stated, are stimulating: it often occasions, when given in somewhat large doses, intoxication, and even actual delirium. If a larger dose be given, the symptoms of diminished action appear without any previous excitement, and are succeeded by delirium, stupor, stertorous breathing, convulsions, and death.

Where opium is given as a stimulus it ought to be administered in small and frequently repeated doses. Where the intention is to mitigate pain or irritation, it ought, on the contrary, to be given in a large dose, and at distant intervals. It is of importance to observe, that where evacuations have been previously procured, or when a state of diaphoresis is present, opium is much more genial and salutary than while the skin is dry, or the bowels torpid.

In continued, as well as intermittent, fevers, opium is given as a stimulus. In the profluviæ of Dr. Cullen, opium is employed to diminish the discharge. In gout it is highly serviceable. In convulsive and spasmodic affections it is often administered to a very great extent, as in the tetanus of warm climates. In lues venerea it is thought to accelerate the action of mercury. It is often given to promote suppuration, and is extremely efficacious in arresting gangrene. In the form of enema opium is often administered in violent affections of the bowels.

Its usual dose is one grain to an adult.

Hyoscyamus niger, indigenous, herba, semen, black henbane. This plant, in its action on the system, bears a considerable resemblance to opium; for which it is often employed as a substitute, where the latter, from idiosyncracy, occasions unpleasant symptoms. It is free from the constipating effects of opium.

Atropa belladonna, indigenous, deadly

nightshade. Both the leaves and berries of this plant, and also its root, are narcotic. It is seldom used in medicine.

Aconitum napellus, aconite, monk's-hood, herba. Europe, America.

Aconite has been employed in obstinate chronic rheumatism, in schirrus, &c. Its dose is from one to two grains of the powdered leaves; of the inspissated juice half a grain.

Conium maculatum, cicuta, hemlock, folia, semen, indigenous. This is a powerful narcotic. Like the aconite, it has been used in schirrous and scrophulous affections,as well as in rheumatisms. Dose two or three grains of the powdered leaves; one or two of the inspissated juice.

Digitalis purpurea, foxglove, folia, indigenous. Of all the narcotics, digitalis most speedily and certainly diminishes the actions of the system, especially of the arteries. It acts at the same time as a stimulant on the absorbent system; hence its abundant utility in dropsy. Lately it has been extensively employed in phthisis, and in the early stages of this disorder with remarkable success. Dose one grain of the powdered leaves, and ten drops of the tincture of the Edinburgh pharmacopœia, gradually increased.

Nicotiana tabacum, tobacco, folia. America. This is a powerful narcotic. Its extreme activity prevents it from being much used in medicine.

Lactuca verosa, strong-scented lettuce, folia, indigenous.

From five to ten grains of the inspissated juice, gradually increased, have been given as a narcotic, diuretic, and antispasmodic.

Datura stramonium, thorn-apple, herba, indigenous.

This has been used in mania, epilepsy, and convulsive diseases. Dose from one to three grains of the inspissated juice.

Arnica montana, leopard's-bane, flores, radix. Germany.

The flowers have been used in the dose of five grains in palsy, convulsions, &c. Its root has been employed as a substitute for Peruvian bark.

Rhododendrum chrysanthum, yellow-flowered rhodadendron, folia, Siberia.

This has been given in chronic rheumatism and gout.

Rhus toxicondendron, poison-oak, folia. N. America. The dried leaves have been used in palsy. Dose half a grain twice or thrice a day.

Strychnos nux vomica, vomica nut. East Indies. It has been employed in mania, hysteria, &c. Dose five grains twice a day.

Prunus lauro-cerasus, cherry-tree laurel, folia, Europe.

This has scarcely been employed in medicine.

OF ANTISPASMODICS.

Antispasmodics form a kind of intermediate class between narcotics and tonics. Spasm sometimes arises from local irritation in states of general irritability, and is sometimes occasioned by pure debility. Both narcotics therefore and tonics are used as antispasmodics; but there are certain substances which in some measure appear to possess a specific antispasmodic power; these we are now to enumerate.

Moschus, musk, moschus moschiferus. South of Asia. Musk is a peculiar substance found in a small sac, situated in the umbilicus in the male of the above animal. Its antispasmodic powers are considerable. Dose from six to twenty grains in the form of bolus: it is useful in much smaller quantities in the convulsions of infants from dentition.

Castoreum, castor, castor fiber. This is a deposition collected in cells near the extremity of the rectum in the beaver. It is much used in hysteria. Dose from ten to twenty grains.

Oleum animale empyreumaticum, empyreumatic animal oil. This is nearly discarded from practice.

Petroleum, a bitumen of a red colour. This was formerly, but is not now, much employed.

Ammonia. This, when employed alone as an antispasmodic, is given in the form of carbonate.

Ferula assafœtida, assafœtida, Persia. This is a concrete juice, obtained by incision from the roots of certain plants. Its dose, as an antispasmodic, is from five to twenty grains.

Sagapenum, gummi-resina, Persia; virtues the same as assafœtida, but inferior in power.

Bubon galbanum, gummi-resina, Africa. Dose ten grains.

Valeriana officinalis, wild valerian: radix, indigenous. This is one of the principal antispasmodics. Dose from one scruple to one drachm, three or four times a day.

Crocus sativus, saffron, indigenous. This substance is composed of the stigmata which crown the pistil of the flower. It has scarcely any virtue.

Melaleucha leucadendron, cajeput oil, India. This is scarcely in use, except as a local application in tooth-ache.

OF TONICS.

This term ought not perhaps to be retained. The agency of tonics is not that of increasing tension or tone, but they are permanent stimulants to the living fibre. Tonics, then, are properly regarded as slow and durable, in opposition to the more diffusible and transient stimuli. They are chosen from the mineral and vegetable kingdom; the former are less speedy and sensible in their action than the latter.

From the mineral Kingdom.

Hydrargyrus, argentum vivum, mercury. *Ferrum*, iron. *Zincum*, zinc. *Cuprum*, copper. *Arsenicum*, arsenic. For the various preparations and medicinal virtues of the above important minerals, consult the articles PHARMACY and MEDICINE.

Barytes, terra ponderosa, heavy earth. This has only been used in medicine combined with muriatic acid. Dr. Crawford introduced the saturated solution into practice as a remedy for scrophula. Dose from five to twenty or more drops.

Calx, lime. This earth exists in nature as a carbonate: like barytes, it has been used as a tonic in combination with muriatic acid.

Acidum nitricum, nitric acid. This acid has been used as a tonic to support the system under a mercurial course. It has likewise been tried, but not with decided and invariable success, as a specific in the cure of lues venerea.

Oxymurias potassæ, oxymuriate of potash. This may be classed as a remedy with the former article. Its dose is, ten grains increased to twenty or twenty-five.

Tonics from the vegetable Kingdom.

The tonic faculty in vegetables is intimately united with certain sensible qualities, with bitterness, astringency, and aroma. The aromatic principle is more active, but less permanent in its stimulating operation. The purest bitters independantly possess a tonic power. Astringency, when it exists exclusively, or as the most predominant principle in vegetables, constitutes a distinct class; the remaining tonics may be arranged according as bitterness or aroma is predominant.

Cinchona officinalis, cortex Peruvianus, Peruvian bark, Peru. Three kinds of this bark are in use, the pale, red, and yellow. The last is now principally employed, as it gives out more bitterness and astringency to water, alcohol, and other media. Peruvian bark was first employed in intermittent fever. In this disease it is given in the dose of a scruple or half a drachm every third hour, during the interval of the paroxysm. In continued fever it is principally employed during the latter stages, when debility is urgent. In rheumatism, erysipelas, gangrene, hæmorrhage, and almost all asthenic disorders, it has been administered as a tonic.

Cinchona Caribæa, Caribeean bark, Caribee islands. *Angustura*, Spanish West Indies. These barks have both been used as substitutes for the Peruvian.

Aristolochia serpentaria, Virginian snakeroot. This is a stimulating aromatic tonic. It is generally given in the form of tincture.

Dorstenia contrayerva, contrayerva, Peru, West Indies. This is scarcely possessed of any virtue.

Croton eleutheria, cascarilla cortex, N. America. This is another substitute for Peruvian bark. Dose a scruple or half a drachm.

Colomba, radix, Ceylon, a very useful tonic bitter. Dose half a drachm.

Quassia excelsa, lignum, West Indies. This is likewise an excellent tonic. Dose, in substance, from ten to thirty grains.

Quassia simarouba, simarouba, cortex, South America. This has been extolled as a remedy in dysentery, and chronic diarrhœa. Dose a scruple.

Swietenia febrifuga, Swietenia, cortex, East Indies. *Swietenia mahagani*, mahogany. Two other proposed substitutes for the Peruvian bark.

Gentiana lutea, gentian, Switzerland, Germany. This is a common and useful remedy in dyspepsia; its virtues are extracted both by water and spirit. Dose in substance half a drachm.

Anthemis nobilis, chamomile, flores, indigenous; a powerful and well-known bitter. N. B. The following plants are now not used in medicine: *artemisia absinthium*, wormwood; *chironia centaurum*, centaury; *marrubium vulgare*, horehound; *menyanthes trifoliata*, trefoil; *centaurea benedicta*, blessed thistle.

AROMATICS.

Citrus aurantium, orange, cortex flavus. The rind of the orange is principally employed as an addition to combinations of bitters used in dyspepsia. It is given in the form of tincture, conserve, and syrup.

Citrus medica, lemon, cortex fructûs,

Asia; similar in flavour and virtue, but rather less bitter than the orange.

Laurus cinnamomum, cinnamon, cortex, Ceylon. This is the most grateful of the aromatics.

Laurus cassia, cassia, cortex, E. Indies. This nearly resembles the cinnamon in appearance, taste, and virtue. It is therefore used with the same intention as this last. Its flavour, however, is less grateful.

Canella alba, cortex, West Indies. This is a moderately strong aromatic: it is not much used except in combination with other substances in the form of tincture.

Acorus calamus, sweet-scented flag, radix, indigenous. This is scarcely at all employed in medicine.

Ammomum zingiber, ginger, radix, East Indies. The dose of ginger is about ten grains.

Kæmpferia rotunda, zedoaria, radix, East Indies. This is seldom employed in medicine.

Santalum album, yellow sanders, lignum, E. Indies. This wood is now nearly banished from practice.

Pterocarpus santalinus, santalum rubrum, red sanders, lignum, India. This, although slightly aromatic, is at present merely used in pharmacy as a colouring ingredient.

Myristica moschata, India. Under the officinal name myristica, both nutmeg and mace are included: the former is the seed, or kernel of the fruit; the latter its capsule. Nutmeg is given as an aromatic in doses of from five to fifteen grains. In larger doses it is narcotic. Mace is employed for the same purposes as nutmeg.

Carophyllus aromaticus, clove, flores, India. Cloves are the unexpanded flowers of the plant. Dose from five to ten grains.

Capsicum annuum, capsicum, Guinea pepper, fructus, E. and W. Indies. This fruit is a very powerful stimulant. It is not in much use as a medicine. Dose from five to ten grains.

Piper nigrum, black pepper, fruit, India. Black pepper is the unripe fruit of the plant. White pepper is the ripe berry of the same vegetable, freed from its outer covering. It is milder than the black. Dose ten or fifteen grains.

Piper longum, long pepper. This is the berry of the plant, gathered before it is fully ripened. It is similar to the black pepper in its qualities.

Piper Cubeba, cubebs, the dried fruit of the tree. It has similar virtues to the other peppers.

Myrtus pimenta, Jamaica pepper, baccæ, W. Indies. This is usually called pimento; it is used in medicine principally on account of its flavour.

Amomum repens, lesser cardamom, semen. Cardamoms form an ingredient in many of the bitter tinctures.

Carum carui, caraway, semen, indigenous. These are in common use, in culinary as well as medicinal preparations.

Coriandum sativum, coriander, semen, South of Europe. These are used with the same intention as caraway.

Pimpinella anisum, anise, semen, Egypt. Anise is used chiefly in the flatulence of children. The four following seeds have similar virtues to the anise and caraway: *Anethum fœniculum*, sweet fennel, semen, indigenous. *Anethum graveolens*, dill, semen, Spain and Portugal. *Cuminum cyminum*, cumin, semen. South of Europe.

Angelica archangelica, garden angelica, semen, folia, radix. North of Europe.

Mentha piperita, peppermint, herba, indigenous. *Mentha viridis*, spear mint, herba, indigenous. *Mentha pulegium*, pennyroyal, herba, indigenous. Of these three mints the first is the most pungent and carminative.

Hyssopus officinalis, hyssop, herba, Asia, South and East of Europe. This plant is nearly similar in virtues to the mints just enumerated.

OF ASTRINGENTS.

Astringents are those substances that restrain morbid evacuations. Their mode of operation has been erroneously supposed similar to that by which dead animal matter is constringed and condensed. Increased evacuations do not depend merely upon mechanical laxity of the solids; the process, therefore, by which they are arrested, cannot entirely be ascribed to chemical principles; although in some cases medicines which are employed to arrest profuse discharges, confessedly possess a power of constringing dead animal fibre. This faculty in vegetables is denominated astringency, and results from the union of gallic acid and tanning principle combined; the former, when separated, is distinguished by its property of striking a deep-black colour with the salts of iron; the other by its great attraction to animal gelatin. Vegetable astringents then may be considered as moderate permanent stimuli, modified in their action, even on living matter, by the principle above alluded to. Inordinate evacuations are, however, often restrained by mineral as well as vegetable substances, and in this case the former deserve to be arranged in the class of astringents, according to the definition above given of these powers. Dr. Darwin refers astringency to the promotion of absorption. Many agents, however, which have the greatest efficacy in exciting the absorbent vessels, are not capable of stopping hæmorrhages, or other morbid discharges.

Vegetable Astringents.

Quercus robur, oak, cortex, indigenous. This has been employed in hæmorrhage, diarrhœa, and intermittent fever. Its dose in powder is from fifteen to thirty grains.

Quercus cerris, galls, south of Europe. These are tubercles found on the branch of the tree which produces them. They are employed in medicine for the same purposes, and are used under the same forms, as oak-bark.

Tormentilla erecta, tormentil, radix, indigenous. This has been used in diarrhœa in decoction. Its dose, in substance, is from half a drachm to a drachm.

Polygonum bistorta, bistort, radix, indigenous. This is a strong astringent. Dose a scruple to a drachm.

Anchusa tinctoria, alkanet, radix, South of Europe. This is at present merely employed as a colouring matter.

Hæmatoxylon Campechianum, logwood. It is used as an astringent under the form of decoction, or watery extract.

Rosa gallica, red rose, South of Europe. The principle use of this astringent is in the form of gargle.

Arbutus uva ursi, bear's whortle-berry, folia, Europe, America. This has been principally given in disorders of the urinary organs. Recently it has been proposed in phthisis pulmonalis.

Mimosa catechu, catechu, or Japan earth, East Indies. This is a powerful and useful astringent in diarrhœa. Its dose is from fifteen to thirty grains. *Kino* is employed with the same intention as catechu. Its dose is from twenty to thirty grains.

Pterocarpus draco, dragon's blood, resina, South America. This is scarcely employed in medicine.

Lacca, lac, ficus indica, resina, East Indies. Lac is very little employed as a medicinal.

Pistacea lentiscus, mastiche, resina, South of Europe. This is likewise discarded from practice.

Mineral Astringents.

The chief of these are the mineral acids, especially the sulphuric, and the compounds this acid affords with metals and earths.

Acidum sulphuricum, vitriolic acid. This is used in hæmoptysis, menorrhagia, diabetes, hectic, &c. It is given in general in the form of diluted acid. Dose from ten to thirty drops.

Argilla, argil, argillaceous earth with oxyd of iron, forming the boles of which the chief is the armenian bole, were formerly employed in, but are now rejected from, practice as nearly inert.

Supersulphas argillæ et potassæ, alum, is given in hæmorrhage, and serous evacuations. Its dose is from five to fifteen grains.

Calx, lime; calx viva, quicklime. Lime has been employed as an astringent in the form of lime-water; it is now not much used.

Carbonas calcis, carbonate of lime. The carbonates of lime are chalk (creta alba), crab's-claws (chelæ cancrorum), oyster-shells (testæ astreorum); they are rather antacids than strictly astringents.

Plumbum, lead. This, in the form of oxyd, or salts, is evidently and powerfully astringent. Its preparations that a e employed are the white oxyd (cerusa, white lead), and the acetate (acetis plumbi, sugar of lead).

Zincum, zinc. The sulphate of zinc (sulphas zinci), and the acetate (acetis zinci), are both powerful astringents. The former is in principal use. It is given sometimes in dysentery, in the dose of two or three grains twice a day. In injections and collyria, it is employed in the proportion of two or three grains to an ounce of water.

Ferrum, iron. The sulphate is the most astringent preparation of iron: it is, however, oftener used as a tonic than astringent.

Cuprum, copper. The saline preparations of this metal are considerably astringent. The sulphas cupri is the most powerful. It has been employed externally as a styptic. The acetite of copper (verdigris) is used as a collyrium from its astringent styptic property.

OF EMETICS.

Emetics are very properly defined by Mr. Murray, "Substances capable of exciting vomiting, independant of any effect arising from the mere quantity of matter introduced into the stomach, or of any nauseous taste or flavour." The phenomenon of vomiting, as to its remote cause, is of difficult explanation. It cannot be owing simply to debilitated, and consequently inverted action of the stomach from previous excitement, as a greater quantity of stimulus may be thrown into this organ without being succeeded by an inversion of its peristaltic motion. Dr. Darwin attributes the effect to a suspension of the exciting power of pleasurable sensation, in consequence of which the fibres of the stomach are arrested for a time, and at length, from the undue accumulation of irritability, their action becomes inverted. The sensation of nausea does not, however, invariably precede the act of vomiting; and even allowing this feeling to be a necessary prelude, the cause of the sensation itself is left unexplained by the sensorial theory of Dr. Darwin.

The utility of emetics under some circumstances of the system is very extensive. Their salutary effects are not solely referable to the discharge which they occasion; but they also produce other changes on the living body, both general and partial, which will be noticed in the article MEDICINE.

Emetics are derived from the vegetable and mineral kingdoms.

Emetics from the vegetable Kingdom.

Ipecacuanha, ipecacuan, radix, South America.

This root is the one in most general use as an emetic: it is both mild and certain in its operation. It is given in a dose from fifteen to thirty grains. Ipecacuan is employed in conjunction with opium, as a diaphoretic. In this case its dose is from three or four to ten grains.

Scilla maritima, squill, radix, South of Europe. This bulbous root of a plant growing on the sandy shores of Spain and Italy, is not at present in much use as an emetic: it is principally employed as an expectorant and diuretic.

Sinapis alba, mustard, semen, indigenous. This perhaps might have been classed among the aromatics. When employed as an emetic, its administration has been principally confined to paralytic affections. It is given in the dose of a tea-spoonful mixed with water.

Asarum Europæum, asarabacca, folia, indigenous. The introduction of ipecacuan into practice, has almost superseded the use of this powerful drug. Dose twenty grains of the dried leaves; of the dried root ten grains.

Nicotiana tabacum, tobacco.

This is a violent emetic, as well as narcotic. It is scarce ever employed in practice.

From the mineral Kingdom.

Antimonium, stibium, antimony.

Than antimony, scarcely any mineral is in more general use: it is, however, seldom used but in a state of combination with oxygen or acid. Its preparations, doses, and virtues, will be treated of under the articles PHARMACY and MEDICINE.

Sulphas zinci, sulphate of zinc.

This salt is sudden in its operation: it is in principal use in cases of poisons having been received into the stomach. Its dose is from ten grains to a scruple.

Sulphas cupri, sulphate of copper.

Neither this nor the acetite of copper is in much use; they are violent in their operation, and in no respect preferable to milder emetics.

OF CATHARTICS.

A discharge of the intestinal contents appears to be occasioned by medicines upon a twofold principle. Cathartics either immediately excite the fibres of the intestines, thus accelerating their peristaltic motion, and consequent fæcal evacuations, or they produce this effect more immediately by stimulating the exhalant and secerning vessels; whose fluids (the bile, pancreatic juice, and intestinal mucus) act as solvents to, and promote the discharge of, the fæces. These latter are milder in their operation than the former: they are classed by Darwin among the secernentia. There are, however, many drugs which act at the same time in each of the above modes.

Cathartics, still more than emetics, are extensively employed in medicine, as capable of operating important changes throughout the system. Their use has recently been brought more systematically into notice.

Upon the grounds just stated, cathartics may with some propriety be divided into purgative and laxative.

Purgatives.

Cassia senna, senna, folia, Egypt, Arabia. This is frequently employed: it is given in the form of infusion. Dose a drachm or more.

Rheum palmatum, rhubarb, radix, Tartary.

The best rhubarb is imported from Turkey. The China rhubarb has less of the aromatic flavour. British rhubarb is much inferior to either. The dose of rhubarb, as a cathartic, is from fifteen grains to two scruples. It is given with advantage in diarrhœa and dysentery, as it contains an astringent principle. In small doses it is stomachic and tonic.

Convolvulus jalapa, jalap, radix, Mexico. This is often administered both alone and more especially with calomel (submurias hydrargyri). Its dose is from fifteen grains to two scruples.

Helleborus niger, black hellebore, radix, Austria, Italy.

This, in a dose from ten to twenty grains, is a violent cathartic. It is seldom employed in modern practice. Dr. Mead attributed a powerful emmenagogue property to to it, which however has scarcely been realized by others. The antient physicians gave it freely in maniacal disorders.

Bryonia alba, bryony, radix, indigenous. This root is not much used. Dose from twenty to thirty grains. It is slightly diuretic.

Cucumis colocynthis, colocynth, fructûs pulpa, Syria.

A drastic purgative in a dose from three to six grains. It is seldom given by itself. It has been chiefly had recourse to in obstinate constipation.

Momordica elaterium, wild cucumber, fructus, south of Europe.

This is the most violent of all purgatives. Its dose is half a grain to two grains.

Rhamnus catharticus, buckthorn, baccarum succus, indigenous. This is seldom used.

Aloe perfoliata, socotrine, Barbadoes, or hepatic and cabbaline aloes; succus spissatus, Africa, Asia, America.

The socotrine aloes is the purest. The Barbadoes and hepatic rank next. The cabbaline is the most impure, and is the weakest. Dose from fifteen grains to a scruple. Its action is principally upon the larger intestines, and on account of the vicinity to, and sympathy of these with, the uterus, it is often useful in amenorrhœa.

Convolvulus scammonia, scammony, gummi-resina, Syria.

This is a very drastic cathartic. Dose from five to ten grains.

Gambogia gutta, gamboge, gummi-resina, East Indies.

Another violent cathartic. Dose from one to four or five grains. In conjunction with the last and following article gamboge is often administered in dropsy.

Submurias hydrargyri, mild muriate of mercury, calomel.

Dose from five to eight or ten grains.

LAXATIVES.

Manna, manna, fraxinus ornus, succus concretus, South of Europe.

This is a mild and pleasant laxative. It is frequently given to children in conjunction with senna. Dose to an adult from one to two ounces.

Cassia fistula, purging cassia, or cassia in the pod; pulpa fructûs, Egypt, East and West Indies.

Dose from four to six drachms.

Tamarindus Indica, tamarind, fructus conditus, E. and W. Indies, America, Arabia.

The tamarinds of the shops is the pulp of the tree mixed with seeds and small fibres, with a quantity of coarse sugar.

It may be taken to the extent of two ounces, or more.

Ricinus communis, palma Christi, oleum, semen, W. Indies.

The oil from the nuts of palma Christi is the castor oil of the shops. This is a mild and very useful purgative.

Sulphur, a simple inflammable substance, and *magnesia*, either pure or carbonated, are all the laxatives that are afforded by the mineral kingdom. The operation of either is exceedingly mild.

For the different neutral salts that are employed as purgatives in medicine, see PHARMACY.

The purgatives that are administered only in the form of enema, are the

Murias sodæ, common salt. An ounce of this dissolved in a pint of tepid water with an ounce of expressed oil, forms the common domestic enema.

Terebinthina veneta, turpentine, pinus larix, gummi-resina. This is sometimes employed as an enema triturated with the yolk of an egg. Dr. Cullen recommends this as a very certain cathartic. It is indicated in obstinate costiveness.

Nicotiana. The introduction per-ano of tobacco smoke has sometimes been effectual in procuring alvine evacuation, after other cathartics have failed. The infusion of from one to two drachms in a pint of water is a more convenient mode of administering this medicine. Much caution is requisite in either case to obviate its injurious effects.

OF EMMENAGOGUES.

These are medicines which promote the menstrual discharge. Obstruction or retention of the menses, unless consequent upon defective conformation, or uterine impregnation, is usually owing to weakness or want of due excitation in the vessels of the uterus.

This debility is best overcome by general stimulating and tonic agents, which thus acting, become emmenagogues, ; sometimes, however, it is necessary more immediately and directly to excite the parts in the vicinity of the uterus, by such purgatives whose action is principally directed to the inferior portion of the intestinal canal. In this case these cathartics prove emmenagogues, but not, as was formerly conjectured, by virtue of any specific power.

Emmenagogues from the class of tonics.

Ferrum, the carbonate of iron, rubigo ferri præparata; is given in a dose of ten or fifteen grains in amenorrhœa; the sulphate of iron in three or four grains. This last is the ferrum vitriolatum of the London pharmacopœia.

Hydrargyrus, the mild muriate of mercury, as already noticed.

Cinchona. This is frequently given in amenorrhœa, in conjunction with some of the preparations of iron.

From the class of antispasmodics.

Castoreum. This is a medicine of very trifling efficacy when used as an emmenagogue. Dose from ten to twenty grains.

Ferula assafœtida, and the other fœtid gums, (galbanum, sagapenum, and ammoniacum) are employed sometimes as emmenagogues. Dose from ten grains to fifteen.

From the class of cathartics.

Aloes. This substance is generally connected with others when given to promote the menses, as in the pilula aloes cum myrrhâ, &c.

Helleborus niger. This is not at present in much repute. Dose of the extract from three to ten grains.

Sinapis alba, semen, mustard-seed in the dose of about half an ounce is sometimes taken as an emmenagogue.

Rosmarinus officinalis, rosemary, summitales florentis. This is now nearly banished from practice.

Rubia tinctorum, madder, radix, south of Europe. Dose from a scruple to half a drachm. Its virtues are not much confided in by modern physicians.

Rutea graveolens, ruta, rue, herba, south of Europe. The herb in the form of infusion, and likewise its essential oil, are the preparations of rue that are given. It is perhaps of inferior efficacy.

Juniperus sabina, savin, folia, south of Europe. Savin is not much used internally, although supposed by some to be a powerful emmenagogue.

OF DIURETICS.

Diuretics are those medicines which augment the urinary discharge. This effect is either produced by a direct stimulus communicated to the kidneys, by a sympathetic excitement of these organs from a previous action excited in the stomach, or, lastly, by the promotion of absorption, by which more than their usual quantity is directed to the secretory vessels of the urine. The saline diaphoretics seem principally to exert their agency in the first of these ways. Squill and others appear to produce a primary action of the stomach, and digitalis from its extraordinary power over the absorbent system is an example of the last-mentioned mode of procuring diuresis.

Saline diuretics.

Supertartris potassæ, cream of tartar. Dose four or six drachms twice a day in a considerable quantity of water. This has been much employed in dropsy.

Nitras potassæ, nitre. Dose from five to twenty grains. Nitre was formerly much used in gonorrhœa, in order to abate the ardor urinæ.

Murias ammoniæ, crude sal ammoniac. This is not much employed. Dose from eight grains to a scruple.

Acetis potassæ, sal diureticus. This has now likewise fallen into disuse.

Potassa, kali. The dose of carbonated kali is from twenty to thirty grains.

Vegetable diuretics.

Scilla maritima. Dose as a diuretic from one to three or four grains.

Digitalis purpurea. Dose from one grain to two or more, of the powdered leaves: from ten to thirty drops of the saturated tincture. The dose requires to be regulated and encreased with much caution.

Nicotiana tabacum. An ounce of the dried leaves infused in a pint of water, has been given as a diuretic in the dose of from sixty to a hundred drops.

Solanum dulcamara, woody nightshade, bitter, sweet, indigenous. This is scarcely ever prescribed.

Lactuca verosa. Dose from ten grains to three drachms. It is not much used.

Colchium autumnale, meadow saffron, indigenous. This has not been in much use in this country. It was first prescribed in dropsy by Storck of Vienna.

Gratiola officinalis, hedge hyssop, south of Europe. The leaves of this plant have likewise been given in dropsy, but they have not come into general use.

Spartium scoparium, broom, summitales, indigenous.

The broom tops infused in water have proved advantageous in dropsy.

Juniperus communis, juniper, baccæ indigenous. Juniper berries given in infusion have a pretty considerable diuretic power.

Copaifera officinalis, copaiva balsam, South America. Dose from twenty to thirty drops twice a day. It is principally employed in gleet.

Pinus larix, Venice turpentine, balsamum. Dose from five to twelve drops of the essential oil. This has likewise been given in gleet, and in ischias.

Pistachia terebinthinus, Cyprus turpentine. This is more fragrant than the balsam from the pinus; as is likewise Strasburgh turpentine, the produce of the pinus picea. The common turpentine (pinus sylvestris balsam) is on the other hand the most offensive.

Diuretics from the animal Kingdom.

Meloe vesicatorius, cantharides, Spanish fly. This is an insect collected from the leaves of plants growing in the South of Europe. It has principally been given internally for gleet and retention of urine. Dose one grain gradually increased.

OF DIAPHORETICS.

If the natural and constant exhalation from the skin be condensed on the surface from its augmented discharge, it constitutes sweat. This effect when produced only to a certain extent, is called diaphoresis. Diaphoretic and sudorific powers differ then only in degree. Diaphoretics are classed by Darwin under the head of secernentia. They necessarily operate by directly or indirectly exciting the cutaneous exhalants. The saline and cooling diaphoretics appear to act in the latter, the heating medicinals which are given to procure sweat in the former manner. Diaphoretics with respect to their influence on the system, are often abundantly powerful and salutary.

Ammonia. All saline preparations are more or less diaphoretic under proper regulation. The ammoniacal salts have been imagined to be so in a greater degree than others. See PHARMACY.

Hydrargyrus. The mild muriate (calomel) in conjunction with opium in very small doses, is sometimes usefully employed as a diaphoretic.

Antimonium. All the preparations of antimony may be made to prove sudorific.

Ipecacuanha. In a dose of two or three grains with or without an opiate.

Opium. This when employed as a diaphoretic is generally combined with one or other of the three former medicines.

Camphor likewise must be united with mercury, antimony, or opium, when it is intended as a diaphoretic.

Guaiacum officinale, guaiac lignum, et gummi-resina, South America, and the West Indies. Guaiac wood is given in the form of decoction, a quart of which is given in the course of the day. The gum-resin is commonly administered in spirit of ammonia, from which it derives a considerable part of its virtues. Dose from one drachm to two of the tincture.

Daphne mezereum mezereon, cortex radicis indigenous. This is a stimulating diaphoretic: it is generally given in lues venerea, with sarsaparilla and guaiac, forming the Lisbon diet-drink.

Smilax sarsaparilla, radix, South America. This has scarcely any power exclusively employed.

Laurus sassafras, sassafras, lignum, America. This is slightly stimulant and diaphoretic. It is probably less efficacious than has generally been imagined.

Cachlearia armoracia, horse-radish, radix, indigenous. This is a stimulant capable of promoting perspiration. About a drachm of the root cut in small pieces and swallowed whole, has been recommended in paralysis, rheumatism, asthma, and dropsy.

Salvia officinalis, sage, folia, south of Europe. Its aqueous infusion drunk warm is slightly stimulant and diaphoretic.

EXPECTORANTS

Are those medicines which facilitate the rejection of mucus or other fluids from the lungs. This object is accomplished by increasing pulmonary exhalation where deficient, or diminishing it when too copious. In the one instance expectorants are secernent, in the other absorbent powers: their operation, like that of emetics, is in both cases either direct or indirect.

Antimonium. The most common preparation of antimony for an expectorant is the emetic tartar of the shops. This is given in pneumonia, catarrh, hooping cough, and asthma, in the dose of one eighth of a grain.

Ipecacuanha. It is given with the same intention in a dose of two or three grains.

Digitalis, in the dose of half a grain, has been used as an expectorant, as likewise

Nicotiana, in the dose of one, two, or three grains.

Scilla. This is one of the most effectual of the expectorantia. Dose one grain of the dried root.

Allium sativum, garlic, radix, south of Europe. Garlic is given in humoral asthma, dropsy, &c. in the dose of half a drachm or two scruples.

Polygala senega, seneka, radix, North America. Dose from ten grains to a scruple. It is chiefly employed in the secondary stage of pneumonia.

Ammoniacum, ammoniac, East Indies, gummi-resina. Dose from ten to thirty grains. This is frequently used as an expectorant.

Assafœtida. Dose from ten to twenty grains.

Myrrha, myrrh, gummi-resina, Abyssinia and Arabia. Dose from ten to twenty grains.

N. B. The plants producing the above two gum-resins are unknown.

Styrax benzoin, benzoin or Benjamin, balsamum, East Indies. Dose ten or fifteen grains. It is perhaps possessed of little power.

Styrax officinale, storax, bals. south of Europe, Asia. Storax is like benzoin in its virtues.

Toluifera balsamum, balsam of tolu, South America. The powers of this balsam are very inconsiderable.

Myroxolon peruiferum, Peruvian balsam, South America. Dose in asthma, leucorrhœa, &c. from five to fifteen grains.

Amyris gileadensis, balm of Gilead, Arabia. The qualities of this nearly resemble the balsam of tolu.

OF SIALAGOGUES.

These are substances which increase the secretion of saliva. This is in general effected by mastication of acrid substances, but in some few instances is occasioned by medicines taken into the stomach. Mercury, perhaps, is the only medicine which uniformly displays a sialagogue power.

Hydrargyrus. All the preparations of mercury have more or less influence over the salivary glands.

Anthemis pyretrum, pellitory of Spain, radix, south of Europe. This is sometimes chewed in order to relieve the tooth-ache.

Arum maculatum, wake-Robin, radix, indigenous. This resembles pellitory, and may be employed with the same intention.

Ginger, mezereum, and tobacco especially, are sometimes used as sialagogues.

ERRHINES

Are medicines which occasion a more than ordinary secretion from the mucous membrane of the nostrils. They all operate by direct application.

Iris florentina, Florentine orris, radix, south of Europe. This is a mild sternutatory and forms one of the ingredients of some cephalic snuffs.

Æsculus hippocastinum, horse chesnut, semen. This acts as a moderate sternutatory.

Origanum majorana, sweet marjorum, herba, south of Europe. This has a slight errhine power.

Lavandula spica, lavender, spicæ florentes, south of Europe. The dried leaves in powder.

Nicotiana, tobacco. The powder of the dried leaves is the basis of snuffs.

Asarum Europœum, asarabaca, folia, indigenous. The leaves of this plant in powder form the basis of officinal sternutatory powders.

Veratrum album, white hellebore, radix, south of Europe. This is a very violent errhine.

Euphorbia officinalis, gummi-resina, Africa. This is the most powerful of all the errhines. It is seldom or never employed.

Subsulphas hydrargyri. This preparation of mercury has been recommended to be snuffed up the nostrils in some kinds of chronic ophthalmia.

EPISPASTICS AND RUBEFACIANTS.

Epispastics are those substances which applied to the skin produce either serous or purulent discharge through the medium of inflammation. Rubefaciants occasion inflammation, but not so violent as to be followed by such discharges.

Meloe vesicatorius, cantharis, Spanish fly. This is the principal substance employed for blistering. After a blister has been raised the discharge is often converted from serum into pus by the continued application of any stimulating acrid ointment. This practice is often pursued in asthma, paralysis, &c.

Cantharides in the form of tincture may be employed simply as a rubefaciant.

Ammonia with oil, forms a liniment for this purpose.

Pinus albus, Burgundy pitch, resina. This is used in the form of plaster, in chronic affections of the lungs and chest.

Sinapis, mustard. The flour of mustard-seed mixed with crumbs of bread, and made into a paste with vinegar, forms a sinapism, a powerful rubefaciant. It is applied to the soles of the feet in cases of pressing debility, as in the last stages of typhoid fever, and in comatose affections.

Allium, garlick. The bruised root of this plant is used for similar purposes with the mustard sinapism.

OF REFRIGERANTS.

Mr. Murray considers those medicines which directly lower the temperature of the body, to be principally chemical in their operation. They are acids, or substances containing a superabundant proportion of oxygen, which being received into the stomach, occasions a less demand for this principle (oxygen) by the lungs, and consequently a less generation or evolution of heat. This doctrine, however, does not appear satisfactory. See PHYSIOLOGY, Sections *Digestion* and *Respiration*; and MEDICINE, Section *Fever*, &c.

Of refrigerants, the vegetable acids are the most efficacious.

Citrus aurantium, orange, succus fructûs. The acidity of China orange is connected with sweetness, of the orange from Seville with bitterness. The former is used as a refrigerant in fever.

Citrus medica, lemon, succus fructûs. The juice of the lemon is composed of citric acid, and saccharine and mucilaginous matter. It is the most powerful and agreeable of the refrigerants. With carbonate of potass, (kali prep.) it forms the saline draught, the virtues of which are perhaps owing to the carbonic acid that is evolved by the mixture of the acid and alkali.

Tamarindus indica. Tamarind is a very pleasant refrigerant: a solution of it in water constitutes a pleasant beverage in fever.

Acidum acetosum, vinegar. The use of this in medicine is principally as a substitute for the lemon-juice.

Supertartris potassæ, cream of tartar.

Nitras potassæ. This is given as a refrigerant, in a dose of from five grains to a scruple.

ANTACIDS.

These perhaps are more strictly chemical in their primary operation than the last class of medicines. They immediately neutralise the prevailing morbid acidity of the stomach.

Alkalies. Pure potass in solution is employed to correct acidity, in doses of fifteen drops in water. The carbonates of potass and soda are, however, in more general use for this purpose.

Aqua ammoniæ is given likewise with this intent. Dose from twenty to forty drops.

Aqua calcis. Lime-water is also used to correct acidity; six or eight ounces being taken occasionally.

Carbonas calcis. Of this there are two varieties, creta alba, (prepared chalk) and chelæ cancrorum (crab's claws). These, especially the former, are principally used in the diarrhœa of infants.

Magnesia (carbonas magnesiæ). This in some cases preferable to chalk as an antacid, as the neutral compound formed by its union with the acid of the stomach proves slightly purgative.

OF LITHONTRIPTICS,

Medicines supposed to have a power of dissolving stone in the bladder. Calculus is principally formed by a peculiar acid, called the lithic, or uric, with which alkalies unite out of the body, and thus become solvents of the stone. These medicines, however, cannot in any way be conveyed to the urinary organs in sufficient quantity to effect this purpose, without material injury to the parts and the general system. It has indeed been ascertained, from experiment, that by the exhibition of alkaline substances, for a length of time, the constitutional disposition to secrete fresh calculus is in a great measure obviated. These substances then are rather preventives than curatives of calculary disorders. That they do not, when taken into the stomach, operate as solvents, is sufficiently evident, from the circumstance of their being more useful when administered saturated with carbonic acid; for these alkaline carbonates do not exert any action on the urinary calculi out of the body, as the lithic acid of the concretion is not of sufficient attractive power to disengage the carbonic acid from its union with the salt. The only power then that is possessed by the medicines termed lithontriptics, is that of neutralizing acidity in the first passages, and thus preventing the deposition of lithic acid in the urinary organs.

Potassa, potass. The dose of the solution of pure potass is 15 or 20 drops gradually increased. The form in which it is generally employed as a lithontriptic, is in the supersaturated solution. Dose, one or two pounds daily.

Soda. This is likewise used in the form of saturated solution, under the name of soda water. Dose, one or two pounds.

Sapo albus. Soap is a combination of expressed oil with potass or soda. Dose, one or two ounces in the course of the day.

Calx. Lime-water is sometimes employed as a lithontriptic.

ESCHAROTICS

Are substances which destroy the texture of both living and dead animal matter. They are employed to consume excrescences, or to open ulcer. Their action on the living system is principally, but not entirely, chemical.

The mineral acids have been employed as escharotics, but are not convenient, in consequence of their fluidity.

Potassa, in its solid state, is a powerful escharotic: mixed with lime it is somewhat milder.

Nitras argenti. Lunar caustic. This is in common use.

Murias antimonii. A powerful caustic, but inconvenient from its being in a fluid form.

Sulphas cupri is often employed.

Acetis cupri. (Verdigris.) This is milder than the sulphate.

Murias hydrargyri. Principally used in venereal ulcers.

Subnitras hydrargyri. Employed with the same intention as the muriate.

Oxydum arsenici albi. A solution of white arsenic is sometimes made use of as an external application to cancer.

Juniperus sabina. Savine is principally applied in the form of ointment to obstinate ulcers. It is used in powder to consume warts.

ANTHELMINTICS

Are those medicines employed to expel worms from the intestinal canal. Their operation is supposed to be mechanical; it may how ver be questioned, whether this class should not be a subdivision of the local stimulants, as the greater number of them seem to discharge worms by a stimulant rather than by a mechanically destructive power.

Dolichos pruriens, cowhage, East and West Indies. This substance is the down growing on the pods of the plant. The action of this medicine may perhaps be principally mechanical.

Ferrum, iron. The filings and rust.

Stannum, tin. This is used in the form of powder. Tin may perhaps operate by a mechanical power. Dose, one or two drachms.

Olea Europæa, olive oil, oleum expressum, South of Europe. Dose half a pound.

Artemisia santonica, worm seed, Persia. Dose half a drachm.

Spigelia marilandica, Indian pink, radix, North America. Dose half a drachm.

Polypodium filix (, male fern, radix, indigenous. Dose two or three drachms.

Tanacetum vulgare, tansy, folia et flores, indigenous. Dose from a scruple to a drachm.

Geoffula inermis, cabbage bark-tree, cortex, Jamaica. Dose thirty grains.

Gambogia. Dose from five to twenty grains.

Submurias hydrargyri. Calomel is perhaps the most efficacious of all the anthelmintics. Dose ten or twelve grains to an adult.

DEMULCENTS

Are substances employed in medicine to shield from acrimony; they can only act on the parts to which they are directly applied. From some circumstances, however, attending their internal administration, it is supposed that they are capable of being absorbed and again separated by particular secretory organs. This supposition does not appear to be entirely satisfactory.

Mimosa nilotica, gum arabic, Africa. This is used to allay the irritation of the fauces in catarrh. It is likewise given in tenesmus, strangury, &c.

Astragalus tragacantha, tragacanth, South of Europe, Asia. This has virtues similar to gum arabic. It is more viscid.

Linum usitatissimum, flax, semen, indigenous. This is sometimes used in gonorrhœa, and catarrh.

Althæa officinalis, marsh mallow, radix, indigenous.

Malva sylvestris, common mallow, folia, indigenous.

Glycyrrhiza glabra, liquorice, radix, South of Europe. These three last are all pleasant demulcents.

Cycas circinalis, sago, East Indies. This is a fæcula from the pith of the plant; it is often given in dysentery, &c. as demulcent and at the same time nutritive.

Orchis mascula, salop, indigenous. Similar in virtue to sago.

Maranta arundinacea, South America. Arrow-root is demulcent, and slightly nutritive.

Tryticum hybernum, wheat, amylum. Starch is useful as an enema with opium in dysentery, &c.

Cornu cervi rasura, hartshorn shavings.

Icthyocolla, isinglass is obtained from the skin of the fish. Isinglass is a demulcent in frequent use.

Olea olivæ. The expressed oil principally used as a demulcent is obtained from the fruit of the olive.

Amygdalus communis, almond oil. Ol. express. South of Europe.

Sævum ceti. Spermaceti is obtained from the head of a certain species of whale. Like the almond oil, it is given as a demulcent in catarrh, &c.

Cera, wax. This is collected from the antheræ of vegetables by bees. This is principally employed in the composition of ointments and plasters.

Of diluents and emollients the two remaining classes scarcely any thing remains to be said. Water, strictly speaking, is the only diluent, and emollients are chiefly formed of heat combined with moisture, as in fomentations and cataplasms, or of unctuous substances, as lard (axungia porcina) and the varieties of expressed oils.

MATHEMATICAL INSTRUMENTS. See INSTRUMENTS.

MATHEMATICS, from μαθησις, originally signified any discipline or learning; but at present denotes that science which teaches or contemplates whatever is capable of being numbered or measured, in so far as computable or measurable, and accordingly is subdivided into arithmetic, which has number for its object, and geometry, which treats of magnitude. See ARITHMETIC, and GEOMETRY.

Mathematics are commonly distinguished into pure and speculative, which consider quantity abstractedly; and mixed, which treat of magnitude as subsisting in material bodies, and consequently are interwoven every where with physical considerations.

Mixed mathematics are very comprehensive; since to them may be referred astronomy, optics, geography, hydrography, hydrostatics, mechanics, fortification, navigation, &c. See ASTRONOMY, OPTICS, &c.

Pure mathematics have one peculiar advantage, that they occasion no disputes among wrangling disputants, as in other branches of knowledge; and the reason is, because the definitions of the terms are premised, and every body that reads a proposition has the same idea of every part of it. Hence it is easy to put an end to all mathematical controversies, by shewing either that our adversary has not stuck to his definitions, or has not laid down true premises; or else that he has drawn false conclusions from true principles; and in case we are able to do neither of these, we must acknowledge the truth of what he has proved.

It is true, that in mixed mathematics, where we reason mathematically upon physical subjects, we cannot give such just definitions as the geometricians; we must therefore rest content with descriptions, and they will be of the same use as definitions, provided we are consistent with ourselves, and always mean the same thing by those terms we have once explained.

MATHIOLA, a genus of the pentandria monogynia class and order. The calyx is entire; corolla tubular, superior, undivided, drupe with a globular nucleus. There is one species, American.

MATRICARIA, *feverfew,* a genus of the polygamia superflua order, in the syngenesia class of plants, and in the natural method ranking under the 49th order, compositæ. The receptacle is naked; there is no pappus; the calyx hemispherical and imbricated, with the marginal leaflets solid, and something sharp. There are eight species, but the only remarkable one is the parthenium or common feverfew, of which there are varieties with double flowers, with semi-double flowers, with double fistular flowers, with a fistular disk and plain radius, with short-rayed flowers, with rayless flowers, with rayless sulphur-coloured heads, and with finely curled leaves. All these varieties flower abundantly in June, each flower being composed of numerous hermaphrodite and female florets; the former compose the disk, the latter the radius or border, and which, in the double and fistulous kinds, are very ornamental in gardens, but of a disagreeable odour; and are all succeeded by plenty of seed in autumn. This plant has received a most extraordinary character in hysteric and other affections of the nerves, as well as for being a carminative or warm stimulating bitter. Dr. Lewis, however, thinks it inferior to camomile; with which he says it agrees in all its sensible qualities, only being somewhat weaker.

MATRICE, or MATRIX, in dyeing, is applied to the five simple colours, whence all the rest are derived or composed. These are, the black, white, blue, red, and yellow, or root-colour. See Dyeing.

Matrice, or *matrices*, used by the letter-founders. See Type.

MATRICES. See Coining.

MATRIX, or Mother Earth, the stone in which metallic ores are found enveloped.

MATROSSES, are soldiers in the train of artillery, who are next to the gunners, and assist them in loading, firing, and spunging the great guns. They carry firelocks, and march along with the store-waggons both as a guard, and to give their assistance in case a waggon should break down.

MATT, in a ship, rope-yarn, junk, &c. beaten flat and interwoven; used in order to preserve the yards from galling or rubbing in hoisting or lowering them.

MATTER. The word matter (materia, which some lexicographers have derived from mater, a mother) denotes, in its primitive sense, that unexplained something from which all those things which are objects of our senses are formed.

The term body is sometimes confounded with that of matter; but they are essentially different. Body is of Saxon origin. It is explained by the Latin words statura, pectus, truncus; and signified the person or form of a man, or other creature; whence it is plain that it ought to be confined to express a substance possessing form or figure.

Substance, both in its etymology and application, approaches nearer to the meaning of the former of these terms. It is well known to be compounded from the Latin preposition sub (under) and the verb stare (to stand). It consequently implies that which supports or stands under the different forms and appearances which are presented to our senses. It is still, however, used in a distinct and more limited sense than matter. It is generally indeed used with the article, to signify a distinct or definite portion of matter; whereas matter in the abstract implies a more confused and general idea of solidity and extension, with little or no regard to figure, proportion, or quantity.

That the whole matter of which this universe of things is composed, is essentially the same, and that the apparent differences which subsist in different bodies depend altogether on the particular distribution or disposition of the component particles, is an opinion which has been entertained by some philosophers of the highest reputation. The wonderful apparent transmutations which take place in the different processes and operations of nature do, it must be confessed, at first sight countenance this hypothesis. A plant will vegetate, and become a solid substance, in the purest water. The generation of stones in the earth, the various phenomena of petrifactions, and a multitude of other facts, contribute greatly, on a fair consideration, to diminish the absurdity of the alchemists (who seem chiefly to have rested on this hypothesis, viz. that all matter was intrinsically the same) and their hopes of converting the basest materials by the efforts of art into the most splendid and valuable of substances.

Mr. Boyle distilled the same water about two hundred times, and at the end of each distillation found a fresh deposit of earth. Margraff repeated the experiment with still greater caution. By means of two glass globes, which communicated with each other, he preserved the water while in the state of vapour from all contact with the air; and on repeated distillation, a quantity of earth of the calcareous kind was deposited at the conclusion of each process.

The extreme rarity and minuteness of the particles into which different substances may be resolved, imparts a still greater degree of probability to this hypothesis; and in general the more any body can be divided, the simpler it appears in its component parts.

We must, however, be cautious of admitting opinions which are not sanctioned by the direct test of experiment; and however plausible the opinion, the accurate observations of modern philosophy have suggested some objections to the homogeneity of matter, which, without further discoveries, it will not be easy to silence.

Whatever phenomena may appear to indicate a transmutation of bodies, or a change of one substance into another, we have the utmost reason, by the latest and best experiments, to believe them merely the effect of different combinations. Thus the conversion of water and air into a solid substance, such as the body of a plant, is merely an apparent conversion; for that solid substance may, by an artificial process, be resolved again into water and air, without any real change in the principles or elementary particles of which those fluids are composed; and the formation of stones, and the phenomena of petrifactions, are accounted for upon much easier principles than that of transmutation. On the other hand, the utmost efforts of chemistry have never been able to proceed farther in the analysis of bodies than to reduce them to a few principles, which appear essentially different from each other, and which have never yet been brought to a more simple form. Thus the matter of fire, or light, appears totally different from that of all other bodies; thus the acid and alkaline principles can never be brought to exhibit the same properties; nor can even the different species of earths be converted into the substance of each other.

If hypothetical reasoning was to be admitted on this occasion, it would probably appear more agreeable to the analogy of nature, to suppose that different substances are formed from the different combinations of a few simple principles in different proportions, than that the very opposite qualities of some of the rarest and most subtile fluids should depend wholly on the different form or modification of the extremely minute particles which enter into their composition.

It is proper, however, to observe, that on this subject there has hitherto appeared no decisive experimental proof on either side. The imperfection of all human efforts, and perhaps of the human faculties themselves, has hitherto confined our investigations to the properties of a few substances, the simplest which chemical analysis has been able to obtain, and which for that reason are denominated elements. See Elements.

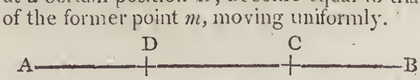
MATTUSCHKÆA, a genus of the tetrandria monogynia class and order. The calyx is four-parted; corolla one-petalled; germ superior, four-cleft. There is one species, a herb of Guiana.

MAURITIA, the *ginkgo*, or *maiden-hair*, a genus of plants belonging to the natural order of palmæ. The calyx of the male is monophyllous; the corolla monopetalous, with six stamina. It is a native of Japan, where it is also known by the names of ginan and itsio. It rises with a long, erect, thick, and branched stem, to the size of a walnut-tree. The bark is ash-coloured, the wood brittle or smooth, the pith soft and fungous. The leaves are large, expanded from a narrow bottom into the figure of a maiden-hair leaf, unequally parted, streaked, without fibres or nerves. From the uppermost shoots hang the flowers in long catkins that are filled with the fertilizing power; and to which succeeds the fruit, adhering to a thick fleshy pedicle, which proceeds from the bosom of the leaves. This fruit is either exactly or nearly round, and of the appearance and size of a damask plum. The substance surrounding the fruit is fleshy juice, white, very harsh, and adheres so firmly to the inclosed nut, as not to be separated from it except by putrefaction. The nut, properly termed gineau, resembles the pistachia nut, especially a Persian species named bergjes pistoia; but is almost double in size, and of the figure of an apricot-stone. The shell is somewhat white, woody, and brittle, and incloses a white loose kernel, having the sweetness of an almond, along with a degree of harshness. These kernels taken after dinner are said to promote digestion, whence they make part of the dessert in great entertainments.

MAXILLA. See Anatomy.

MAXIMUM, in mathematics, denotes the greatest quantity attainable in any given case. If a quantity conceived to be generated by motion, increases, or decreases, till it arrives at a certain magnitude or position, and then, on the contrary, grows less or greater, and it be required to determine the said magnitude or position, the question is called a problem de maximis et minimis.

Thus, let a point m move uniformly in a right line, from A towards B, and let another point n move after it, with a velocity either increasing or decreasing, but so that it may, at a certain position D, become equal to that of the former point m, moving uniformly.



This being premised, let the motion of n be first considered as an increasing one; in which case the distance of n behind m will continually increase, till the two points arrive at the contemporary positions C and D; but afterwards it will again decrease; for the motion of n till then being slower than at D, it is also slower than that of the preceding point m (by the hypothesis), but becoming quicker afterwards than that of m, the distance $m\,n$ (as has been already said) will again decrease; and therefore is a maximum, or the greatest of all, when the celerities of the two points are equal to each other.

But if n arrives at D with a decreasing celerity, then its motion being first swifter, and afterwards slower, than that of m, the distance $m\,n$ will first decrease and then increase, and therefore is a minimum, or the least of all, in the forementioned circumstance. Since then the distance $m\,n$ is a maximum, or a minimum, when the velocities of m and n are equal, or when that distance increases as fast through the motion of m as it decreases by that of n, its fluxion at that instant is evidently equal to nothing. Therefore, as the motion of the points m and n may be conceived such that their distance mn may express the measure of any variable quantity whatever, it follows, that the fluxion of any variable quantity whatever, when a maximum or a minimum, is equal to nothing.

The rule therefore to determine any flowing quantity in an equation proposed, to an extreme value, is: having put the equation into fluxions, let the fluxion of that quantity whose extreme value is sought be supposed equal to nothing; by which means all those members of the equation in which it is found will vanish, and the remaining ones will give the determination of the maximum or minimum required.

Prob. I. To divide a given right line into two such parts, that their product, or rectangle, may be the greatest possible. This is the case when the line is bisected or divided into equal parts. See Fluxions.

In any mechanical engine the proportion of the power to the weight, when they balance each other, is found by supposing the engine to move, and reducing their velocities to the respective directions in which they act; for the inverse ratio of those velocities is that of the power to the weight according to the general principle of mechanics. But it is of use to determine likewise the proportion they ought to bear to each other, that when the power prevails, and the engine is in motion, it may produce the greatest effect in a given time. When the power prevails, the weight moves at first with an accelerated motion; and when the velocity of the power is invariable, its action upon the weight decreases, while the velocity of the weight increases. Thus the action of a stream of water or air upon a wheel, is to be estimated from the excess of the velocity of the fluid above the velocity of the part of the engine which it strikes, or from their relative velocity only. The motion of the engine ceases to be accelerated when this relative velocity is so far diminished, that the action of the power becomes equal to the resistance of the engine arising from the gravity of the matter that is elevated by it, and from friction; for when these balance each other, the engine proceeds with the uniform motion it has acquired.

Prob. II. Let a denote the velocity of the stream, u the velocity of the part of the engine which it strikes when the motion of the machine is uniform, and $a - u$ will represent their relative velocity. Let A represent the weight which would balance the force of the stream when its velocity is a, and p the weight which would balance the force of the same stream if its velocity was only $a - u$; then $p : A :: \overline{a-u}^2 : a^2$, or $p = A \times \frac{\overline{a-u}^2}{aa}$, and p shall represent the action of the stream upon the wheel. If we abstract the friction, and have regard to the quantity of the weight only, let it be equal to qA, (or be to A as q to 1); and because the motion of the machine is supposed uniform, $p = q \times A = \frac{A \times \overline{a-u}^2}{aa}$, or $q = \frac{\overline{a-u}^2}{aa}$. The momentum of this weight is $qAu = \frac{Au \times \overline{a-u}^2}{aa}$; which is a maximum when the fluxion of $\frac{u \times \overline{a-u}^2}{aa}$ vanishes, that is, when $u \times \overline{a-u}^2 - 2uu \times a - u = 0$, or $a - 3u = 0$. Therefore, in this case, the machine will have the greatest effect if $u = \frac{a}{3}$, or the weight $qA = \frac{A \times \overline{a-u}^2}{aa} = \frac{4A}{9}$; that is, if the weight that is raised by the engine be less than the weight which would balance the power in the proportion of 4 to 9: and the momentum of the weight is $\frac{4Aa}{27}$.

Prob. III. Suppose that the given weight P (plate Miscel. fig. 156.) descending by its gravity in the vertical line, raises a given weight W by the cord PMW (that passes over the pulley M) along the inclined plane BD, the height of which BA is given; and let the position of the plane BD be required, along which W will be raised in the least time from the horizontal line AD to B.

Let $AB = a$, $BD = x$, $t =$ time in which W describes DB; then the force which accelerates the motion of W is $P - \frac{aW}{x}$, tt is as $\frac{xx}{Px - aW}$, and if we suppose the fluxion of this quantity to vanish, we shall find $x = \frac{2aW}{P}$, or $P = \frac{2aW}{x}$; consequently the plane BD required is that upon which a weight equal to 2W would be sustained by P; or if BC be the plane upon which W would sustain P, then $BD = 2BC$. But if the position of the plane BD be given, and W being supposed variable, it be required to find the ratio of W to P, when the greatest momentum is produced in W along the given plane BD; in this case, W ought to be to P as BD to $BA + \sqrt{BD + BA} + \sqrt{BA}$.

Questions of this kind may be likewise demonstrated from the common elementary geometry, of which the following may serve as an example.

Prob. IV. Let a fluid, moving with the velocity and direction AC (plate Miscel. fig. 157), strike the plane CE; and suppose that this plane moves parallel to itself in the direction CB, perpendicular to CA, or that it cannot move in any other direction; then let it be required to find the most advantageous position of the plane CE, that it may receive the greatest impulse from the action of the fluid. Let AP be perpendicular to CE in P, draw AK parallel to CB, and let PK be perpendicular upon it in K; and AK will measure the force with which any particle of the fluid impels the plane EC in the direction CB. For the force of any such particle being represented by AC, let this force be resolved into AQ parallel to EC and AP perpendicular to it; and it is manifest, that the latter AP only has any effect upon the plane CE. Let this force AP be resolved into the force AL perpendicular to CB, and the force AK parallel to it; then it is manifest, that the former, AL, has no effect in promoting the motion of the plane in the direction CB; so that the latter, AK, only, measures the effort by which the particle promotes the motion of the plane CE, in the direction CB. Let EM and EN be perpendicular to CA and CB, in M and N; and the number of particles moving with directions parallel to AC, incident upon the plane CE, will be as EM. Therefore the effort of the fluid upon CE, being as the force of each particle, and the number of particles together, it will be as $AK \times EM$; or, because AK is to AP ($=$ EM) as EN to CE, as $\frac{EM^2 EM \times EN}{CE}$; so that CE being given, the problem is reduced to this, to find when $EM^2 \times EN$ is the greatest possible, or a maximum. But because the sum of EM^2 and of EN^2 ($= CM^2$) is given, being always equal to CE^2, it follows that $EN^2 \times EM^4$ is greatest when $EN^2 = \frac{1}{3}CE^2$; for when the sum of two quantities AC and CB (fig. 158.) was given, $AC \times BC^2$ is greatest when $AC = \frac{1}{3}AB$, as will be very evident if a semicircle is described upon AD. But when $EN^2 \times EM^4$ is greatest, its square root $EN \times EM^2$ is of necessity at the same time greatest. Therefore the action of the fluid upon the plane CE, in the direction CB, is greatest when $EN^2 = \frac{1}{3}CE^2$, and consequently $EM^2 = \frac{2}{3}CE^2$; that is, when EM, the sine of the angle ACE, in which the stream strikes the plane, is to the radius, as $\sqrt{2}$ to $\sqrt{3}$; in which case it easily appears from the trigonometrical tables, that this angle is of 54° 44′.

Several useful problems in mechanics may be resolved by what we have just now shewn. If we represent the velocity of the wind by AC, a section of the sail of a windmill perpendicular to its length by CE, as it follows from the nature of the engine, that its axis ought to be turned directly to the wind, and the sail can only move in a direction perpendicular to the axis, it appears, that, when the motion begins, the wind will have the greatest effect to produce this motion, when the angle ACE, in which the wind strikes the sail, is of 54° 44′. In the same manner, if CB represent the direction of the motion of a ship, or the position of her keel, abstracting from her lee-way, and AC be the direction of the wind perpendicular to her way, then the most advantageous position of the sail CE, to promote her motion in the direction CB, is when the angle ACE, in which the wind strikes the sail, is of 54° 44′. The best position of the rudder, where it may have the greatest effect in turning round the ship, is determined in like manner.

Prob. V. To find the internal dimensions of a cylindrical cup, whose capacity is equal to a, when the cup is made with the least possible quantity of silver of a given thickness.

Put the diameter $= x$; and .7854 (the area of a circle whose diameter is 1) $= c$: then, by El. xii. 2, $cx^2 =$ the area of the bottom, and therefore $\frac{a}{cx^2} =$ the altitude; but $4cx =$ the circumference of the bottom, and therefore $4cx \times \frac{a}{cx^2} = \frac{4a}{x} =$ the inside curve superficies. Hence $cx^2 + \frac{4a}{x} =$ the whole inside superficies, which is a minimum; and therefore its fluxion is $= 0$: that is, $2cx\dot{x} - \frac{4a\dot{x}}{x^2} = 0$, or $2cx^3\dot{x} - 4a\dot{x} = 0$, or $cx^3 - 2a = 0$, therefore $cx^3 = 2a$, and $x = \sqrt[3]{\frac{2a}{c}} =$ diameter. By substituting this quantity for x in $\frac{a}{cx^2}$, we have

$$\frac{a}{c \times \overline{\frac{2a}{c}}^{\frac{2}{3}}} = \frac{a \times \overline{\frac{2a}{c}}^{\frac{1}{3}}}{c \times \frac{2a}{c}} = \frac{a}{c} \times \frac{\overline{\frac{2a}{c}}^{\frac{1}{3}}}{\frac{2a}{c}} = \frac{ac}{2ac} \times \overline{\frac{2a}{c}}^{\frac{1}{3}} = \frac{1}{2} \times \overline{\frac{2a}{c}}^{\frac{1}{3}} = \text{altitude}.$$

Since then the diameter is $\overline{\frac{2a}{c}}^{\frac{1}{3}}$ and the altitude is half that quantity, they will be to one another as 2 to 1, to answer the conditions of the problem.

Prob. VI. To find the greatest cone that can be inscribed in a given sphere.

Let AD (plate Miscel. fig. 159) the diameter of the sphere $= a$; .7854 (the area of a circle whose diameter is 1) $= c$; and AC, the altitude of the cone, $= x$; then CD $= a - x$. By El. iii. 35, AC $\times$ CD $=$ CB^2, that is, $x \times \overline{a - x} = ax - x^2 =$ CB^2; but the square of the diameter is four times the square of the radius; therefore, by El. xii. 2, $4acx - 4cx^2 =$ the area of the cone's base, which, by El. xii. 10, drawn into $\frac{1}{3}x$, is $\frac{4}{3}acx^2 - \frac{4}{3}cx^3 =$ the cone's solidity, which is a maximum; therefore, by taking away what is common, we get $ax^2 - x^3$ a maximum, the fluxion of which is $= 0$, that is, $2ax\dot{x} - 3x^2\dot{x} = 0$, or $2a = 3x$, and $x = \frac{2a}{3}$. So that the cone will be a maximum, when its altitude is equal to two-thirds of the sphere's diameter.

MEAD, an agreeable liquor made of honey and water. See HONEY.

There are many receipts for making mead, of which the following is one of the best. Take four gallons of water, and as much honey as will make it bear an egg; add to this the rind of three lemons, boil it, and scum it well as it rises. Then take it off the fire, and add the three lemons cut in pieces; pour it into a clean tub or open vessel, and let it work for three days, then scum it well, and pour off the clear part into a cask, and let it stand open till it ceases to make a hissing noise; then stop it up close, and in three months time it will be fine and fit for bottling. If you would give it a finer flavour, take cloves, mace, and nutmeg, of each four drams; beat them small, tie the powder in a piece of cloth, and put it into the cask.

MEADOW. See HUSBANDRY.

MEAN, a middle state between two extremes; as a mean motion, mean distance, arithmetical mean, geometrical mean, &c.

Arithmetical MEAN, is half the sum of the extremes. So, 4 is an arithmetical mean between 2 and 6, or between 3 and 5. or between 1 and 7; also an arithmetical mean between a and b is $\frac{a+b}{2}$, or $\frac{1}{2}a + \frac{1}{2}b$.

Geometrical MEAN, commonly called a mean proportional, is the square root of the product of the two extremes; so that, to find a mean proportional between two given extremes, multiply these together, and extract the square root of the product. Thus, a mean proportional between 1 and 9, is $\sqrt{1 \times 9} = \sqrt{9} = 3$; a mean between 2 and $4\frac{1}{2}$ is $\sqrt{2 \times 4\frac{1}{2}} = \sqrt{9} = 3$ also; the mean between 4 and 6 is $\sqrt{4 \times 6} = \sqrt{24}$; and the mean between a and b is $\sqrt{ab}$.

The geometrical mean is always less than the arithmetical mean between the same two extremes. So the arithmetical mean between 2 and $4\frac{1}{2}$ is $3\frac{1}{4}$, but the geometrical mean is only 3. To prove this generally, let a and b be any two terms, a the greater, and b the less; then, universally, the arithmetical mean $\frac{a+b}{2}$ shall be greater than the geometrical mean $\sqrt{ab}$, or $a + b$ greater than $2\sqrt{ab}$. For, by squaring both, they are $a^2 + 2ab + b^2 > 4ab$; subtr. $4ab$ from each, then $a^2 - 2ab + b^2 > 0$, that is, - - - - $(a - b)^2 > 0$.

To find a Mean Proportional geometrically, between two given lines M and N. Join the two given lines together at C, in one continued line AB; upon the diameter AB describe a semicircle, and erect the perpendicular CD; which will be the mean proportional between AC and CB, or M and N.

To find two Mean Proportionals between two given extremes. Multiply each extreme by the square of the other, viz. the greater extreme by the square of the less, and the less extreme by the square of the greater; then extract the cube root out of each product, and the two roots will be the two mean proportionals sought. That is, $\sqrt[3]{a^2b}$ and $\sqrt[3]{ab^2}$ are the two means between a and b. So, between 2 and 16, the two mean proportionals are 4 and 8; for $\sqrt[3]{2^2 \times 16} = \sqrt[3]{64} = 4$, and $\sqrt[3]{2 \times 16^2} = \sqrt[3]{512} = 8$.

In a similar manner we proceed for three means, or four means, or five means, &c.; from all which it appears, that the series of the several numbers of mean proportionals between a and b will be as follows: viz.

1 mean, $\sqrt{ab}$;
2 means, $\sqrt[3]{a^2b}, \sqrt[3]{ab^2}$;
3 means, $\sqrt[4]{a^3b}, \sqrt[4]{a^2b^2}, \sqrt[4]{ab^3}$;
4 means, $\sqrt[5]{a^4b}, \sqrt[5]{a^3b^2}, \sqrt[5]{a^2b^3}, \sqrt[5]{ab^4}$;
5 means, $\sqrt[6]{a^5b}, \sqrt[6]{a^4b^2}, \sqrt[6]{a^3b^3}, \sqrt[6]{a^2b^4}, \sqrt[6]{ab^5}$:
&c. &c.

Harmonical MEAN, is double a fourth proportional to the sum of the extremes, and the two extremes themselves a and b: thus, as $a + b : a :: 2b : \frac{2ab}{a+b} = m$, the harmonical mean between a and b. Or it is the reciprocal of the arithmetical mean between the reciprocals of the given extremes; that is, take the reciprocals of the extremes a and b, which will be $\frac{1}{a}$ and $\frac{1}{b}$; then take the arithmetical mean between these reciprocals, or half their sum, which will be $\frac{1}{2a} + \frac{1}{2b}$, or $\frac{a+b}{2ab}$; lastly, the reciprocal of this is $\frac{2ab}{a+b} = m$, the harmonical mean: for arithmeticals and harmonicals are mutually reciprocals of each other;

so that if a, m, b, &c. be arithmeticals,

then shall $\frac{1}{a}$, $\frac{1}{m}$, $\frac{1}{b}$, &c. be harmonicals;

or if the former be harmonicals, the latter will be arithmeticals.

For example, to find a harmonical mean between 2 and 6: here $a = 2$, and $b = 6$; therefore $\frac{2ab}{a+b} = \frac{2 \times 2 \times 6}{2 + 6} = \frac{24}{8} = 3 = m$, the harmonical mean sought between 2 and 6.

Pappus has shewn a curious similarity that subsists between the three different sorts of means: a, m, b, being three continued terms, either arithmeticals, geometricals, or harmonicals, then in the

Arithmeticals $a : a :: a - m : m - b$
Geometricals $a : m :: a - m : m - b$
Harmonicals $a : b :: a - m : m - b$.

MEASLES. See MEDICINE.

MEASURE *of an angle*, is an arch described from the vertex in any place between its legs. Hence angles are distinguished by the ratio of the arches, described from the vertex between the legs to the peripheries. Angles then are distinguished by those arches; and the arches are distinguished by their ratio to the periphery: thus an angle is said to be so many degrees as there are in the said arch. See ANGLE.

MEASURE *of a figure*, or plane surface, is a square whose side is one inch, one foot, one yard, or some other determinate length. Among geometricians, it is usually a rod called a square rod, divided into 10 square feet, and the square feet into 10 square digits.

MEASURE *of a solid*, is a cube whose side is one inch, foot, yard, or any other determinate length. In geometry it is a cubic perch, divided into cubic feet, digits, &c. Hence cubic measures, or measures of capacity. See SPHERE, CUBE, &c.

MEASURE *of velocity*, in mechanics, the space passed over by a moving body in a given time. To measure a velocity therefore, the space must be divided into as many equal parts as the time is conceived to be divided into; the quantity of space answering to such a part of time is the measure of the velocity.

MEASURE, in geometry, denotes any quantity assumed as one, or unity, to which the ratio of the other homogeneous or similar quantities is expressed.

Measures in a legal and commercial sense are various, according to the various kinds and dimensions of the things measured. Hence arise lineal or longitudinal measures, for lines or lengths; square measures, for areas or superficies; and solid or cubic measures, for bodies and their capacities; all which again are very different in different countries and in different ages, and even many of them for different commodities. Whence arise other divisions of antient and modern measures, domestic and foreign ones, dry measures, liquid measures, &c.

I. *Long measures, or measures of application.*

1. The English and Scotch standards.

The English lineal standard is the yard, containing 3 English feet, equal to 3 Paris feet 1 inch and $\frac{3}{12}$ of an inch, or $\frac{7}{9}$ of a Paris ell. The use of this measure was established by Henry I. of England, and the standard taken from the length of his own arm. It is divided into 36 inches, and each inch is supposed equal to 3 barley-corns. When used for measuring cloth, it is divided into 4 quarters, and each quarter subdivided into 4 nails. The English ell is equal to a yard and a quarter, or 45 inches, and is used in measuring linens imported from Germany and the Low-countries.

The Scots elwand was established by king David I. and divided into 37 inches. The standard is kept in the council-chamber of Edinburgh, and being compared with the English yard, is found to measure $37\frac{1}{5}$ inches; and therefore the Scots inch and foot are larger than the English, in the proportion of 180 to 185; but this difference being so inconsiderable, is seldom attended to in practice. The Scots ell, though forbidden by law, is still used for measuring some coarse commodities, and is the foundation of the land-measure of Scotland.

Itinerary measure is the same both in England and Scotland. The length of the chain is 4 poles, or 22 yards; 80 chains make a mile. The old Scots computed miles were generally about a mile and a half each.

The reel for yarn is $2\frac{1}{2}$ yards, or 10 quarters, in circuit; 120 threads make a cut, 12 cuts make a hasp or hank, and 4 hanks make a spindle.

2. The French standard was formerly the aune or ell, containing 3 Paris feet, 7 inches, 8 lines, or 1 yard $\frac{2}{7}$ English; the Paris foot royal exceeding the English by $\frac{682}{1000}$ parts, as in one of the following tables. This ell is divided two ways, viz. into halves, thirds, sixths, and twelfths; and into quarters, half-quarters, and sixteenths.

The French, however, have also formed an entirely new system of weights and measures, according to the following table:

Proportions of the measures of each species to its principal measure or unity.	First part of the name which indicates the proportion to the principal measure or unity.	PRINCIPAL MEASURES OR UNITIES.				
		Length.	Capacity.	Weight.	Agrarian.	For firewood.
10,000 1,000 100 10 0 0.1 0.01 0.001	Myria Kilo Hecto Deca —— Deci Centi Milli	Metre.	Litre.	Gramme.	Are.	Stere.
Proportion of the principal measures between themselves, and the length of the meridian.		10,000,000th part of the dist. from the pole to the equator.	A decimetre cube.	Weight of a centimetre cube of distilled water.	100 square metres.	One cubic metre.
Value of the principal measures in the antient French measures.		3 feet 11 lines and $\frac{1}{2}$ nearly.	1 pint and $\frac{1}{20}$, or 1 litron and $\frac{1}{4}$ nearly.	18 grains and 841,000 parts.	Two square perches des eaux et forêt.	1 demi-voie, or $\frac{1}{4}$ of a cord des eaux et forêt.
Value in English measures.		Inches 39.383	61.083 inches, which is more than the wine and less than the beer quart.	22.966 grains.	11.968 square yards.	

3. The English avoirdupois pound weighs 7004 troy grains; whence the avoirdupois ounce, whereof 16 make a pound, is found equal to 437.75 troy grains. And it follows, that the troy pound is to the avoirdupois pound as 88 to 107 nearly; for as 88 to 107, so is 5760 to 7003.636: that the troy ounce is to the avoirdupois ounce, as 80 to 73 nearly; for as 80 to 73, so is 480 to 438: and, lastly, that the avoirdupois pound and ounce are to the Paris two-marc weight and ounce, as 63 to 68 nearly; for as 63 to 68, so is 7004 to 7559.873. See WEIGHT. 4. The Paris foot expressed in decimals is equal to 1.0654 of the English foot, or contains 12.785 English inches.

3. The standard in Holland, Flanders, Sweden, a good part of Germany, many of the Hanse-towns, as Dantzick and Hamburgh, and at Geneva, Franckfort, &c. is likewise the ell; but the ell in all these places differs from the Paris ell. In Holland it contains one Paris foot 11 lines, or 4-sevenths of the Paris ell. The Flanders ell contains 2 feet 1 inch 5 lines and half a line, or 7-twelfths of the Paris ell. The ell of Germany, Brabant, &c. is equal to that of Flanders.

4. The Italian measure is the bracchio, brace, or fathom. This obtains in the states of Modena, Venice, Florence, Lucca, Milan, Mantua, Bologna, &c. but is of different lengths. At Venice it contains 1 Paris foot, 11 inches, 3 lines, or 8-fifteenths of the Paris ell. At Bologna, Modena, and Mantua, the brace is the same as at Venice. At Lucca it contains 1 Paris foot, 9 inches, 10 lines, or half a Paris ell. At Florence it contains 1 foot, 9 inches, four lines, or 49-hundredths of a Paris ell. At Milan, the brace for measuring of silks is 1 Paris foot, 7 inches, 4 lines, or 4 ninths of a Paris ell; that for woollen cloths is the same with the ell of Holland. Lastly, at Bergama, the brace is 1 foot 7 inches, 6 lines, or 5-ninths of a Paris ell. The usual measure at Naples, however, is the canna, containing 6 feet, 10 inches, and 2 lines, or one Paris ell and 15-seventeenths.

5. The Spanish measure is the vara or yard, in some places called the barra; containing 17 twenty-fourths of the Paris ell. But the measure in Castile and Valencia is the pan, span, or palmi; which is used, together with the canna, at Genoa. In Arragon, the vara is equal to a Paris ell and a half, or 5 feet, 5 inches, 6 lines.

6. The Portuguese measure is the cavedos, containing 2 feet, 11 lines, or four-sevenths of a Paris ell; and the vara, 106 whereof make a 100 Paris ell.

7. The Piedmontese measure is the ras, containing 1 Paris foot, 9 inches 10 lines, or half a Paris ell. In Sicily, their measure is the canna, the same with that of Naples.

8. The Muscovite measures are the cubit, equal to 1 Paris foot, 4 inches, 2 lines; and the arcin, two whereof are equal to 3 cubits.

9. The Turkish and Levant measures are the picq, containing 2 feet, 2 inches, and 2 lines, or three-fifths of the Paris ell. The Chinese measure is the cobre, ten whereof are equal to three Paris ells. In Persia, and some parts of the Indies, the gueze, of which there are two kinds; the royal gueze, called also the gueze monkelser, containing 2 Paris feet, 10 inches, 11 lines, or four-fifths of the Paris ell; and the shorter gueze, called simply gueze, only two-thirds of the former. At Goa and Ormuz, the measure is the vara, the same with that of the Portuguese, having been introduced by them. In Pegu, and some other parts of the Indies, the cando or candi, equal to the ell of Venice. At Goa, and other parts, they use a larger cando, equal to 17 Dutch ells, exceeding that of Babel and Balsora by $\frac{7}{8}$ per centum, and the vara by $6\frac{1}{2}$. In Siam, they use the ken, short of three Paris feet by one inch. The ken contains two soks, the sok two keubs, the keub 12 nious or inches, the niou to be equal to eight grains of rice, *i. e.* to about nine lines. At Camboia they use the haster; in Japan the tatam; and the span on some of the coasts of Guinea.

A TABLE

Of the Measures of Length of the principal Places in Europe, compared with the English Yard.

		Eng. yard.
100 Aunes, or ells of England, equal to		125
100	of Holland or Amsterdam	75
100	of Brabant or Antwerp	76
100	of France	$128\frac{1}{4}$
100	of Hamburgh, Francfort, &c.	$62\frac{1}{2}$
100 Aunes	of Breslau	60
100	of Dantzick	$66\frac{3}{4}$
100	of Bergen and Drontheim	$68\frac{1}{4}$
100	of Sweden or Stockholm	$65\frac{3}{4}$
100	of St. Gall, for linens	$87\frac{1}{2}$
100	of ditto, cloths	67
100	of Geneva	$124\frac{3}{4}$
100 Canes	of Marseilles and Montpelier	$214\frac{1}{2}$
100	of Toulouse & High Languedoc	200
100	of Genoa, of 9 palms	$245\frac{1}{4}$
100 Canes	of Rome	$227\frac{1}{4}$
100 Varas	of Spain	$93\frac{3}{4}$
100	of Portugal	123
100 Cavidos	of Portugal	75
102 Brasses	of Venice	$73\frac{1}{2}$
100	of Bergamo, &c.	$71\frac{1}{4}$
100	of Florence and Leghorn	64
100	of Milan	$58\frac{1}{2}$

N. B. The aunes or ells of Amsterdam, Haerlem, Leyden, the Hague, Rotterdam, and other cities of Holland, as also that of Nuremberg, being all equal, are comprehended under that of Amsterdam; as those of Osnaburg are under those of France; and those of Bern and Basil are equal to those of Hamburg, Francfort, and Leipsic.

For the subdivisions and multiples of each of these measures of length, see the article Aune.

For the proportion of the feet of the principal nations in Europe, compared with the English foot, see the article Foot.

Square, or *Superficial* Measures. English square or superficial measures are raised from the yard of 36 inches multiplied into itself, and thus producing 1296 square inches in the square yard: the divisions of this are square feet and inches; and the multiples, poles, roods, and acres, as in the following table:

English Square-Measures.

Inches						
144	Foot					
1296	9	Yard				
3600	25	$2\frac{7}{9}$	Pace			
39204	$272\frac{1}{4}$	$30\frac{1}{4}$	10.89	Pole		
1568160	10890	1210	435.6	40	Rood	
6272640	43560	4840	1743.6	160	4	Acre.

Roman Square-Measure reduced to English.

The integer was the jugerum or acre, which the Romans divided like the libra or as: thus, the jugerum contained

	Square feet.	Scruples.	English roods.	Square poles.	Square feet.
As	28800	288	2	18	250.05
Deunx	26400	264	2	10	183.85
Dextans	24000	240	2	2	117.64
Dodrans	21600	216	1	34	51.42
Bes	19200	192	1	25	257.46
Septunx	16800	168	1	17	191.25
Semis	14400	144	1	9	125.03
Quincunx	12000	120	1	1	58.82
Triens	9600	96	0	32	264.85
Quadrans	7200	72	0	24	198.64
Sextans	4800	48	0	16	132.43
Uncia	2400	24	0	8	66.21

Note. Actus major was 14400 square feet, equal to a semis; clima, 3600 square feet, equal to sescuncia; and actus minimus equal to a sextans.

Cubical Measures, *or Measures of capacity for liquids.* The English measures were originally raised from troy-weight; it being enacted by several statutes that eight pounds troy of wheat, gathered from the middle of the ear, and well dried, should weigh a gallon of wine-measure, the divisions and multiples whereof were to form the other measures; at the same time it was also ordered, that there should be but one liquid measure in the kingdom: yet custom has prevailed, and there having been introduced a new weight, viz. the avoirdupois, we have now a second standard gallon adjusted thereto, and therefore exceeding the former in the proportion of the avoirdupois weight to troy weight.

From this latter standard are raised two several measures, the one for ale, the other for beer.

The sealed gallon at Guildhall, which is the standard for wines, spirits, oils, &c. is supposed to contain 231 cubic inches and on this supposition the other measures raised therefrom, will contain as in the table underneath; yet, by actual experiment, made in 1688, before the lord-mayor and the commissioners of excise, this gallon was found to contain only 224 cubic inches: it was however agreed to continue the common supposed contents of 231 cubic inches; so that all computations stand on their old footing. Hence, as 12 is to 231, so is $14\frac{12}{20}$ to $281\frac{1}{2}$ the cubic inches in the ale gallon: but in effect the ale quart contains $70\frac{1}{2}$ cubic inches, on which principle the ale and beer gallon will be 282 cubic inches. The several divisions and multiples of these measures, and their proportions, are exhibited in the following tables:

Measure *for horses*, is the hand, which by statute contains four inches.

MEATUS AUDITORIUS. See Anatomy.

MECHANICS, that branch of practical mathematics which considers motion and moving powers, their nature and laws, with their effects in machines.

The term mechanics is equally applied to the doctrine of the equilibrium of powers, more properly called statics; and to that science which treats of the generation and communication of motion, which constitutes mechanics strictly so called. See Statics, Power, Motion, &c.

The knowledge of mechanics is one of those things, says Mr. Mac Laurin, that serve to distinguish civilized nations from barbarians. It is by this science that the utmost improvement is made of every power and force in nature; and the motions of the elements, water, air, and fire, are made subservient to the various purposes of life; for however weak the force of man appears to be, when unassisted by this art; yet, with its aid, there is hardly any thing above his reach. It is distinguished by sir Isaac Newton into practical and rational mechanics; the former of which treats of the mechanical powers, viz. the lever, balance, axis and wheel, pulley, wedge, screw, and inclined plane.

Rational mechanics comprehends the whole theory of motion, shews when the powers or forces are given how to determine the motions that are produced by them; and conversely when the phænomena of the motions are given, how to trace the powers or forces from which they arise.

Mechanical powers are simple engines that enable men to raise weights, to move heavy bodies, and overcome resistances, which they could not do with their natural strength alone. Their importance to society is incalculable. Every machine whatever is composed of one or more of them, sometimes of several combined together.

In considering this science, it will be necessary at first to take some things for granted that are not strictly true; and after the theory is established, to make the proper allowances for them.

1. That a small portion of the earth's surface, which is spherical, may be considered as a plane. 2. That all bodies be supposed to descend in lines parallel to each other; for though all bodies really tend to the centre of the earth, yet the distance from which they fall is comparatively so small, that their inclination towards each other is inconsiderable. 3. That all planes be considered as perfectly smooth; levers to be inflexible, and without thickness or weight; cords perfectly pliable; and machines without friction and inertia.

Three things are always to be considered in treating of mechanical engines; the weight to be raised, the power by which it is to be raised, and the instrument or engine by which this is to be effected.

The mechanical powers are generally reckoned six; the lever, the pulley, the wheel and axis, the inclined plane, the wedge, and the screw.

These perhaps may be reduced to two; for the pulley and wheel are only assemblages of levers, and the wedge and screw are inclined planes.

To calculate the power of a machine, it is usually considered in a state of equilibrium; that is, in the state when the power which is to overcome the resistance just balances it. Having discovered what quantity of power will be requisite for this purpose, it will then be necessary to add so much more as to overcome the friction and weight of the machine itself, and to give the necessary velocity.

The *lever* is the simplest of all machines; and is only a straight bar of iron, wood, or other material, supported on, and moveable round, a prop called the fulcrum.

In the lever there are three circumstances to be principally attended to: 1. The fulcrum, or prop, by which it is supported, or on which it turns as an axis, or centre of motion: 2. The power to raise and support the weight: 3. The resistance or weight to be raised or sustained.

The points of suspension are those points where the weights really are, or from which they hang freely. The power and the weight are always supposed to act at right angles to the lever, except it is otherwise expressed.

The lever is distinguished into three sorts, according to the different situations of the fulcrum or prop, and the power, with respect to each other. 1. When the prop is placed between the power and the weight. 2. When the prop is at one end of the lever, the power at the other, and the weight between them. 3. When the prop is at one end, the weight at the other, and the power applied between them.

A poker, in stirring the fire, is a lever of the first sort: the bar of the grate upon which it rests is the fulcrum; the fuel, the weight to be overcome; and the hand is the power. The lever of the first kind is principally used for loosening large stones; or to raise great weights to small heights, in order to get ropes under them, or other means of raising them to still greater heights; it is the most common species of lever.

ABC, Plate Mechanics, fig. 1. is this lever, in which B is the fulcrum, A the end at which the power is applied, and C the end where the weight acts.

To find when an equilibrium will take place between the power and the weight, in this as well as in every other species of lever, it is necessary to recollect, that when the momenta, or quantities of force, in two bodies are equal, they will balance each other. Now let us consider when this will take place in the lever. Suppose the lever AB (fig. 2) to be turned on its axis, or fulcrum, so as to come into the situation DC; as the end D is farthest from the centre of motion, and as it has moved through the arch AD in the same time as the end B moved through the arch BC, it is evident that the velocity of AB must have been greater than that of B. But the momenta being the products of the quantities of matter multiplied into the velocities, the greater the velocity, the less the quantity of matter need be to get the same product. Therefore, as the velocity of A is the greatest, it will require less matter to produce an equilibrium than B.

Let us next see how much more weight B will require than A to balance it. As the radii of circles are in proportion to their circumferences, they are also proportionate to similar parts of them; therefore, as the arches AD, CB, are similar, the radius or arm DE bears the same proportion to EC that the arch AD bears to CB. But the arches AD and CB represent the velocities of the ends of the lever, because they are the spaces which they moved over in the same time; therefore the arms DE and EC may also represent these velocities.

It is evident then, that an equilibrium will take place when the length of the arm AE multiplied into the power A, shall equal EB multiplied into the weight B; and consequently, that the shorter EB is, the greater must be the weight B; that is, the power and the weight must be to each other inversely, as their distances from the fulcrum. Thus, suppose AE, the distance of the power from the prop, to be 20 inches, and EB, the distance of the weight from the prop, to be eight inches, also the weight to be raised at B to be five pounds, then the power to be applied at A must be two pounds; because the distance of the weight from the fulcrum eight, multiplied into the weight five, makes 40; therefore 20, the distance of the power from the prop, must be multiplied by two, to get an equal product, which will produce an equilibrium.

It is obvious, that while the distance of the power from the prop exceeds that of the weight from the prop, a power less than the weight will raise it, so that then the lever affords a mechanical advantage: when the distance of the power is less than that of the weight from the prop, the power must be greater than the weight to raise it; when both the arms are equal, the power and the weight must be equal, to be in equilibrio.

The second kind of lever, when the weight is between the fulcrum and the power, is represented by fig. 3. in which A is the fulcrum, B the weight, and C the power. The advantage gained by this lever, as in the first, is as great as the distance of the power from the prop exceeds the distance of the weight from it. Thus if the point *a*, on which the power acts, is seven times as far from A as the point b, on which the weight acts, then one pound applied at C will raise seven pounds at B.

This lever shews the reason why two men carrying a burden upon a stick between them, bear shares of the burden which are to one another in the inverse proportion of their distances from it. For it is well known, that the nearer either of them is to the burden, the greater share he bears of it; and if he goes directly under it, he bears the whole. So if one man is at A, and the other at a, having the pole or stick resting on their shoulders; if the burden or weight B is placed five times as near the man at A, as it is to the man a, the former will bear five times as much weight as the latter.

This is likewise applicable to the case of two horses of unequal strength to be so yoked, that each horse may draw a part proportionable to his strength; which is done by so dividing the beam they pull, that the point of traction may be as much nearer to the stronger horse than to the weaker, as the strength of the former exceeds that of the latter.

To this kind of lever may be reduced oars, rudders of ships, doors turning upon hinges, cutting-knives which are fixed at the point, &c.

If in this lever we suppose the power and weight to change places, so that the power may be between the weight and the prop, it will become a lever of the third kind; in which, that there may be a balance between the power and the weight, the intensity of the power must exceed the intensity of the weight just as much as the distance of the weight from the prop exceeds the distance of the power. Thus, let E (fig. 4.) be the prop of the lever EF, and W a weight of one pound, placed three times as far from the prop as the power P acts at F, by the cord going over the fixed pulley D: in this case the power must be equal to three pounds, in order to support the weight of one pound.

To this sort of lever are generally referred the bones of a man's arm; for when he lifts a weight by the hand, the muscle that exerts its force to raise that weight is fixed to the bone about one-tenth part as far below the elbow as the hand is. And the elbow being the centre round which the lower part of the arm turns, the muscle must therefore exert a force ten times as great as the weight that is raised.

As this kind of lever is a disadvantage to the moving power, it is used as little as possible; but in some cases it cannot be avoided, such as that of a ladder, which being fixed at one end, is by the strength of a man's arms reared against a wall.

What is called the hammer-lever differs in nothing but its form, from a lever of the first kind. Its name is derived from its use, that of drawing a nail out of wood by a hammer.

Suppose the shaft of a hammer to be five times as long as the iron part which draws the nail, the lower part resting on the board as a fulcrum; then by pulling backwards the end of the shaft, a man will draw a nail with one-fifth part of the power that he must use to pull it out with a pair of pincers, in which case the nail would move as fast as his hand; but with the hammer the hand moves five times as much as the nail, by the time that the nail is drawn out.

Let ACB (fig. 5.) represent a lever of this sort, bent at C, which is its prop, or centre of motion. P is a power acting upon the longer arm AC, at A, by the means of the cord DA going over the pulley D; and W is a weight or resistance acting upon the end B of the shorter arm CB. If the power is to the weight as CB is to CA, they are in equilibrio: thus, suppose W to be five pounds, acting at the distance of one foot from the centre of motion C, and P to be one pound, acting at A, five feet from the centre C; the power and weight will just balance each other.

Thus we see, that in every species of lever there will be an equilibrium, when the power is to the weight, as the distance of the weight from the fulcrum is to the distance of the power from the fulcrum.

In making experiments on the mechanic powers, some difficulties arise from the weight of the materials; but as it is impossible to find any that are without weight, we take care that they are perfectly balanced themselves, before the weights and powers are applied. The bar, therefore, used in making experiments on levers, has the short end so much thicker than the long arm, as will be sufficient to balance it on the prop.

Hitherto we have supposed that the power and weight acted perpendicularly upon the lever; but if they do not, they act with less force upon it; the power should, therefore, if possible, be always made to act at right angles to the lever.

If several levers are combined together in such a manner, as that a weight being appended to the first lever, may be supported by a power applied to the last, as in fig. 6. (which consists of three levers of the first kind, and is so contrived, that a power applied at the point L of the lever C, may sustain a weight at the point S of the lever A), the power must here be to the weight, in a ratio, or proportion, compounded of the several ratios, which those powers that can sustain the weight by the help of each lever, when used singly and apart from the rest, have to the weight. For instance: if the power which can sustain the weight P by the help of the lever A, is to the weight as 1 to 5; and if the power which can sustain the same weight by the lever B alone, is to the weight as 1 to 4; and if the power which could sustain the same weight by the lever C, is to the weight as 1 to 5; then the power which will sustain the weight by the help of the three levers joined together, will be to the weight in a proportion consisting of the several proportions multiplied together, of 1 to 5, 1 to 4, and 1 to 5; that is, of 1 to 100.

For since, in the lever A, a power equal to one-fifth of the weight P pressing down the lever at L, is sufficient to balance the weight; and since it is the same thing whether that power is applied to the lever A at L, or the lever B at S, the point S bearing on the point L; a power equal to one-fifth of the weight P, being applied to the point S of the lever B, will support the weight; but one-fourth of the same power being applied to the point L of the lever B, and pushing the same upward, will as effectually depress the point S of the same lever, as if the whole power was applied at S; consequently a power equal to one-fourth of one-fifth, that is, one-twentieth of the weight P, being applied to the point L of the lever B, and pushing up the same, will support the weight; in like manner, it matters not whether that force is applied to the point L of the lever B, or to the point S of the lever C, since, if S be raised, L, which rests on it, must be raised also; but one-fifth of the power applied at the point L of the lever C, and pressing it downwards, will as effectually raise the point S of the same lever, as if the whole power was applied at S, and pushed up the same; consequently a power equal to one-fifth of one-twentieth, that is, one-hundredth part of the weight P, being applied to the point L of the lever C, will balance the weight at the point S of the lever A.

The balance, an instrument of very extensive use in comparing the weights of bodies, is a lever of the first kind, whose arms are of equal length. The points from which the weights are suspended being equally distant from the centre of motion, will move with equal velocity; consequently, if equal weights are applied, their momenta will be equal, and the balance will remain in equilibrio.

In order to have a balance as perfect as possible, it is necessary to attend to the following circumstances: 1. The arms of the beam ought to be exactly equal, both as to weight and length. 2. The points from which the scales are suspended should be in a right line, passing through the centre of gravity of the beam; for by this the weights will act directly against each other, and no part of either will be lost on account of any oblique direction. 3. If the fulcrum, or point upon which the beam turns, is placed in the centre of gravity of the beam, and if the fulcrum and the points of suspension are in the same right line, the balance will have no tendency to one position more than another, but will rest in any position it may be placed in, whether the scales are on or off, empty or loaded.

If the centre of gravity of the beam, when level, is immediately above the fulcrum, it will overset by the smallest action; that is, the end which is lowest will descend; and it will do this with more swiftness, the higher the centre of gravity is, and the less the points of suspension are loaded.

But if the centre of gravity of the beam is immediately below the fulcrum, the beam will not rest in any position but when level; and if disturbed from that position, and then left at liberty, it will vibrate, and at last come to rest on the level. In a balance, therefore, the fulcrum ought always to be placed a little above the centre of gravity. Its vibrations will be quicker, and its horizontal tendency stronger, the lower the centre of gravity, and the less the weight upon the points of suspension.

4. The friction of the beam upon the axis ought to be as little as possible; because, should the friction be great, it will require a considerable force to overcome it; upon which account, though one weight should a little exceed the other, it will not preponderate, the excess not being sufficient to overcome the friction, and bear down the beam. The axis of motion should be formed with an edge like a knife, and made very hard; these edges are at first made sharp, and then rounded with a fine hone, or piece of buff leather, which causes a sufficient bluntness, or rolling edge. On the regular form and excellence

of this axis, depends chiefly the perfection of the instrument.

5. The pivots which form the axis or fulcrum, should be in a straight line, and at right angles to the beam. 6. The arms should be as long as possible, relatively to their thickness, and the purposes for which they are intended; as the longer they are, the more sensible is the balance.

They should also be made as stiff and inflexible as possible; for if the beam is too weak, it will bend, and become untrne. 7. The rings, or the piece on which the axis bears, should be hard and well polished, parallel to each other, and of an oval form, that the axis may always keep its proper bearing, or remain always at the lowest point.

Very delicate balances are not only useful in nice experiments, but are likewise much more expeditious than others in common weighing. If a pair of scales with a certain load is barely sensible to one-tenth of a grain, it will require a considerable time to ascertain the weight to that degree of accuracy, because the turn must be observed several times over, and is very small. But if no greater accuracy was required, and scales were used which would turn with one-hundredth of a grain, a tenth of a grain more or less would make so great a difference in the turn, that it would be seen immediately.

The statera, or Roman steel-yard, is a lever of the first kind, and is used for finding the weights of different bodies, by one single weight placed at different distances from the prop or centre of motion D (fig. 7.). For the shorter arm DG is of such a weight as exactly to counterpoise the longer arm DX. If this arm is divided into as many equal parts as it will contain, each equal to GD, the single weight P (which we may suppose to be one pound) will serve for weighing any thing as heavy as itself, or as many times heavier as there are divisions in the arm DX, or any quantity between its own weight and that quantity. As for example, if P is one pound, and placed at the first division 1 in the arm DX, it will balance one pound in the scale at W; if it is removed to the second division at 2, it will balance two pounds in the scale; if to the third three pounds; and so on to the end of the arm DX. If any of these integral divisions is subdivided into as many equal parts as a pound contains ounces, and the weight P is placed at any of these subdivisions, so as to counterpoise what is in the scale, the pounds and odd ounces therein will by that means be ascertained.

The wheel and axle is a machine much used, and is made in a variety of forms. It consists of a wheel with an axle fixed to it, so as to turn round with it; the power being applied at the circumference of the wheel, and the weight to be raised is fastened to a rope which coils round the axle.

AB (fig. 9.) is a wheel and CD an axle fixed to it, and which moves round with it. If the rope which goes round the wheel is pulled, and the wheel turned once round, it is evident that as much rope will be drawn off as the circumference of the wheel; but while the wheel turns once round, the axle turns once round; and consequently the rope by which the weight is suspended, will wind once round the axis, and the weight will be raised through a space equal to the circumference of the axis.

The velocity of the power, therefore, will be to that of the weight, as the circumference of the wheel to that of the axis.

That the power and the weight may be in equilibrio, therefore, the power must be to the weight as the circumference of the wheel to that of the axis.

It is proved by geometry that the circumferences of different circles bear the same proportion to each other as their respective diameters do; consequently the power is to the weight, as the diameter also of the axis to that of the wheel.

Thus, suppose the diameter of the wheel to be eight inches, and the diameter of the axis to be one inch; then one ounce acting as the power P, will balance eight ounces as a weight W; and a small additional force will cause the wheel to turn with its axis, and raise the weight; and for every inch which the weight rises, the power will fall eight inches.

The wheel and axis may be considered as a kind of perpetual lever, of which the fulcrum is the centre of the axis, and the long and short arms are the diameter of the wheel and the diameter of the axis. See fig. 10.

From this it is evident, that the larger the wheel, and the smaller the axis, the stronger is the power of this machine; but then the weight must rise slower in proportion.

A capstan is a cylinder of wood, with holes in it, into which are put bars, or levers, to turn it round; these are like the spokes of a wheel without the rim. Sometimes the axis is turned by a winch fastened to it, which in this respect serves for a wheel; and is more powerful in proportion to the largeness of the circle it describes, compared with the diameter of the axle.

When the parts of the axis differ in thickness, and weights are suspended at the different parts, they may be sustained by one and the same power applied to the circumference of the wheel; provided the product arising from the multiplication of the power into the diameter of the wheel, is equal to the sum of the products arising from the multiplication of the several weights into the diameters of those parts of the axis from which they are suspended.

In considering the theory of the wheel and axle, we have supposed the rope that goes round the axle to have no sensible thickness; but as in practice this cannot be the case, if it is a thick rope, or if there are several folds of it round the axis, you must measure to the middle of the outside rope, to obtain the diameter of the axis, for the distance of the weight from the centre is increased by the coiling up of the rope.

If teeth are cut in the circumference of a wheel, and if they work in the teeth of another wheel of the same size, as fig. 11, it is evident that both the wheels will revolve in the same time; and the weight appended to the axle of the wheel B, will be raised in the same time as if the axle had been fixed to the wheel A. But if the teeth of the second wheel are made to work in teeth made in the axle of the first, as at fig. 12, as every part of the circumference of the second wheel is applied successively to the circumference of the axle of the first, and as the former is much greater than the latter, it is evident that the first wheel must go round as many times more than the second, as the circumference of the second wheel exceeds that of the first axle.

In order to a balance here, the power must be to the weight, as the product of the circumferences, or diameters of the two axles multiplied together, is to the circumferences or diameters of the two wheels.

This will become sufficiently clear, if it is considered as a compound lever, which was explained above. Instead of a combination of two wheels, three or four wheels may work in each other, or any number; and by thus increasing the number of wheels, or by proportioning the wheels to the axis, any degree of power may be acquired.

To this sort of engine belong all cranes for raising great weights; and in this case the wheel may have cogs all round it, instead of handles; and a small lanthorn, or trundle, may be made to work in the cogs, and be turned by a winch, which will make the power of the engine to exceed the power of the man who works it, as much as the number of revolutions of the winch exceeds those of the axle CD, fig. 9, when multiplied by the excess of the length of the winch above the length of the semidiameter of the axle, added to the semidiameter or half-thickness of the rope K, by which the weight is drawn up. Thus, suppose the diameter of the rope and axle taken together to be 13 inches, and consequently half their diameter to be $6\frac{1}{2}$ inches, so that the weight W will hang at $6\frac{1}{2}$ inches perpendicular distance from below the centre of the axle. Now, let us suppose the wheel AB, which is fixed on the axle, to have 80 cogs, and to be turned by means of a winch $6\frac{1}{2}$ inches long, fixed on the axle of a trundle of eight staves, or rounds, working in the cogs of the wheel; here it is plain, that the winch and trundle would make ten revolutions for one of the wheel AB, and its axis CD, on which the rope K winds in raising the weight W; and the winch being no longer than the sum of the semidiameters of the great axle and rope, the trundle could have no more power on the wheel than a man could have by pulling it round by the edge, because the winch would have no greater velocity than the edge of the wheel has, which we here suppose to be ten times as great as the velocity of the rising weight; so that, in this case, the power gained would be as 10 is to 1. But if the length of the winch is 13 inches, the power gained will be as 20 to 1; if $19\frac{1}{2}$ inches (which is long enough for any man to work by), the power gained will be as 30 to 1; that is, a man could raise 30 times as much by such an engine, as he could do by his natural strength without it, because the velocity of the handle of the winch would be 30 times as great as the velocity of the rising weight; the absolute force of any engine being in the proportion of the velocity of the power, to the velocity of the weight raised by it. But then, just as much power or advantage as is gained by the engine, so much time is lost in working it, which is common in all mechanical cases whatever.

In this sort of machines it is requisite to have a ratchet wheel on the end of the axle C, with a catch to fall into its teeth; which will at any time support the weight, and keep it from descending, if the person who turns the handle should, through inadvertence or carelessness, quit his hold while the weight is rising. By this means, the danger is prevented which might otherwise happen by the running down of the weight when left at liberty.

The *pulley* is a small wheel turning on an axis, with a drawing-rope passing over it: the small wheel is usually called a sheeve, and is so fixed in a box, or block, as to be moveable round a pin passing through its centre.

Pulleys are of two kinds:—1. Fixed, which do not move out of their places; 2. Moveable, which rise and fall with the weight.

When a pulley is fixed, as fig. 13, two equal weights suspended to the ends of a rope passing over it, will balance each other; for they stretch the rope equally, and if either of them is pulled down through any given space, the other will rise through an equal space in the same time; and consequently, as the velocities of both are equal, they must balance each other. This kind of pulley, therefore, gives no mechanical advantage; so that you can raise no greater weight by it than you could do by your natural strength. Its use consists in changing the direction of the power, and sometimes enabling it to be applied with more convenience. By it, a man may raise a weight to any point, without moving from the place he is in; whereas, otherwise, he would have been obliged to ascend with the weight: it also enables several men together to apply their strength to the weight by means of the rope.

The moveable pulley represented at A (fig. 14), is fixed to the weight W, and rises and falls with it. In comparing this to a lever, the fulcrum must be considered as at A; the weight acts upon the centre, and the power is applied at the extremity of the lever D. The power, therefore, being twice as far from the fulcrum as the weight is, the proportion between the power and weight, in order to balance each other, must be as 1 to 2. Whence it appears, that the use of this pulley doubles the power, and that a man may raise twice as much by it as by his strength alone. Or it may be considered in this way: Every moveable pulley hangs by two ropes equally stretched, and which must, consequently, bear equal parts of the weight; but the rope A B being made fast at B, half the weight is sustained by it; and the other part of the rope, to which the power is applied, has but half the weight to support; consequently the advantage gained by this pulley is as 2 to 1.

When the upper and fixed block contains two pulleys, which only turn upon their axes, and the lower moveable block contains also two, which not only turn on their axis, but rise with the weight F (fig. 15), the advantage gained is as 4 to 1. For each lower pulley will be acted upon by an equal part of the weight; and because in each pulley that moves with the weight, a double increase of power is gained, the force by which F may be sustained, will be equal to half the weight divided by the number of lower pulleys; that is, as twice the number of lower pulleys is to 1, so is the weight suspended to the power.

But if the extremity C (fig. 16) is fixed to the lower block, it will sustain half as much as a pulley; consequently here the rule will be, as twice the number of pulleys adding unity is to 1, so is the weight to the power.

These rules hold good, whatever may be the number of pulleys in the blocks.

If, instead of one rope going round all the pulleys, the rope belonging to each pulley is made fast at top, as in fig. 17, a different proportion between the power and the weight will take place. Here it is evident, that each pulley doubles the power: thus, if there are two pulleys, the power will sustain four times the weight.

Fig. 8, is the concentric pulley, invented by Mr. James White. O, R, are two brass blocks, in which grooves are cut; and round these a cord is passed, by which means they answer the purpose of so many distinct pulleys. The advantage gained is found by doubling the number of grooves in the lower block.

It is common to place all the pulleys in each block on the same pin, by the side of each other, as in fig. 18; but the advantage, and rule for the power, are the same here as in figs. 15 and 16.

A pair of blocks with the rope fastened round it, is commonly called a tackle.

The *inclined plane*. This mechanical power is of very great use in rolling up heavy bodies, such as casks, wheelbarrows, &c. It is formed by placing boards, or earth, in a sloping direction.

The force wherewith a body descends upon an inclined plane, is to the force of its absolute gravity, by which it would descend perpendicularly in free space, as the height of the plane is to its length. For suppose the plane A B (fig. 19) to be parallel to the horizon, the cylinder C will keep at rest on any part of the plane where it is laid. If the plane is placed perpendicularly, as A B, fig. 20, the cylinder C will descend with its whole force of gravity, because the plane contributes nothing to its support or hindrance; and therefore it would require a power equal to its whole weight to keep it from descending.

Let A B (fig. 21) be a plane parallel to the horizon, and A D a plane inclined to it; and suppose the whole length A D to be three times as great as the perpendicular D B. In this case, the cylinder E will be supported upon the plane D A, and kept from rolling, by a power equal to a third part of the weight of the cylinder; therefore a weight may be rolled up this inclined plane, by a third part of the power which would be sufficient to draw it up by the side of an upright wall.

It must also be evident, that the less the angle of elevation, or the gentler the ascent is, the greater will be the weight which a given power can draw up; for the steeper the inclined plane is, the less does it support of the weight; and the greater the tendency which the weight has to roll, consequently the more difficult for the power to support it: the advantage gained by this mechanical power, therefore, is as great as its length exceeds its perpendicular height.

To the inclined plane may be reduced all hatchets, chisels, and other edge-tools.

The *wedge* is the fifth mechanical power or machine: it may be considered as two equally inclined planes, joined together at their bases; then D G (fig. 22) is the whole thickness of the wedge at its back A B G D, where the power is applied; E F is the depth or height of the wedge; B F the length of one of its sides; and O F is its sharp edge, which is entered into the wood intended to be split, by the force of a hammer or mallet striking perpendicularly on its back. Thus, A B (fig. 23) is a wedge driven into the cleft C E D of the wood F G.

When the wood does not cleave at any distance before the wedge, there will be an equilibrium between the power impelling the wedge downward, and the resistance of the wood acting against the two sides of the wedge, when the power is to the resistance as half the thickness of the wedge at its back is to the length of either of its sides; because the resistance then acts perpendicular to the sides of the wedge. But when the resistance on each side acts parallel to the back, the power that balances the resistances on both sides will be, as the length of the whole back of the wedge is to double its perpendicular height.

When the wood cleaves at any distance before the wedge (as it generally does), the power impelling the wedge will not be to the resistance of the wood as the length on the back of the wedge is to the length of both its sides, but as half the length of the back is to the length of either side of the cleft, estimated from the top or acting part of the wedge. For, if we suppose the wedge to be lengthened down from the top C E, to the bottom of the cleft at D, the same proportion will hold; namely, that the power will be to the resistance as half the length of the back of the wedge is to the length of either of its sides: or, which amounts to the same thing, as the whole length of the back is to the length of both the sides.

The wedge is a very great mechanical power, since not only wood, but even rocks, can be split by it; which it would be impossible to effect by the lever, wheel and axle, or pulley; for the force of the blow, or stroke, shakes the cohering parts, and thereby makes them separate more easily.

The *screw* (fig. 24.) is the sixth and last mechanical power, but cannot properly be called a simple machine, because it is never used without the application of a lever or winch to assist in turning it; and then it becomes a compound engine of a very great force, either in pressing the parts of bodies closer together, or in raising great weights. It may be conceived to be made by cutting a piece of paper, A B C (fig. 25), into the form of an inclined plane, or half-wedge; and then wrapping it round a cylinder (fig. 26), the edge of the paper A C will form a spiral line round the cylinder, which will give the thread of the screw. It being evident that the winch must turn the cylinder once round, before the weight of resistance can be moved from one spiral winding to another; therefore, as much as the circumference of a circle described by the handle of the winch is greater than the interval or distance between the spirals, so much is the force of the screw. Thus, supposing the distance of the spirals to be half an inch, and the length of the winch twelve inches, the circle described by the handle of the winch where the power acts will be 76 inches nearly, or about 152 half-inches, and consequently 152 times as great as the distance between the spirals: and therefore a power at the handle, whose intensity is equal to no more than a single pound, will balance 152 pounds acting against the screw; and as much additional force as is sufficient to overcome the friction, will raise the 152 pounds; and the velocity of the power will be to the velocity of the weight, as 152 to 1. Hence it appears, that the longer the winch is, and the nearer the spirals are to one another, so much the greater is the force of the screw.

A machine for shewing the force or power of the screw may be contrived in the following manner:—Let the wheel C have a screw (fig. 24) on its axis, working in the teeth of the wheel D, which suppose to be 48 in number. It is plain, that for every time the wheel C and screw are turned round by the winch A, the wheel D will be moved one tooth by the screw; and therefore, in 48 revolutions of the winch, the wheel D will be turned once round. Then, if the circumference of a circle, described by the handle of the winch A, is equal to the circumference of a groove round the wheel D, the velocity of the handle will be 48 times as great as the velocity of any given point in the groove. Consequently, if a line G goes round the groove, and has a weight of 48 pounds hung to it, a power equal to 1 pound at the handle will balance and support the weight. To prove this by experiment, let the circumferences of the grooves of the wheels C and D be equal to one another; and then if a weight H, of 1 pound, is suspended by a line going round the groove of the wheel C, it will balance a weight of 48 pounds hanging by the line G; and a small addition to the weight H will cause it to descend, and so raise up the other weight.

If a line G, instead of going round the groove of the wheel D, goes round its axle I, the power of the machine will be as much increased as the circumference of the groove exceeds the circumference of the axle; which supposing to be six times, then one pound at H will balance six times 48, or 288 pounds, hung to the line on the axle: and hence the power or advantage of this machine will be as 288 to 1. That is, a man who by his natural strength could lift a hundredweight, will be able to raise 288 cwts. by this engine. If a system of pulleys was applied to the cord H, the power would be increased to an amazing degree.

When a screw acts in a wheel in this manner, it is called an endless screw.

When it is not employed in turning a wheel, it consists of two parts: the first is called the male or outside screw; being cut in such a manner, as to have a prominent part going round the cylinder in a spiral manner, which prominent part is called the thread of the screw; the other part, which is called the female, or inside screw, is a solid body, containing a hollow cylinder, whose concave surface is cut in the same manner as the convex surface of the male screw, so that the prominent parts of the one may fit the concave parts of the other.

A very considerable degree of friction always acts against the power in a screw; but this is fully compensated by other advantages; for on this account the screw continues to sustain a weight, even after the power is removed, or ceases to act, and presses upon the body against which it is driven. Hence the screw will sustain very great weights; insomuch that several screws properly applied, would support a large building, whilst the foundation was mending, or renewed.

OF COMPOUND MACHINES.

Though it is evident from the principles delivered above, that any one of the mechanical powers is capable of overcoming the greatest possible resistance, in theory; yet, in practice, if used singly for producing very great effects, they would be frequently so unwieldy and unmanageable, as to render it impossible to apply them. For this reason, it is generally found more advantageous to combine them together; by which means the power is more easily applied, and many other advantages are obtained. In all machines, simple as well as compound, what is gained in power is lost in time. Suppose that a man, by a fixed pulley, raises a beam to the top of a house in two minutes, it is clear that he will be able to raise six beams in twelve minutes; but by means of a tackle, with three lower pulleys, he will raise the six beams at once, with the same ease as he before raised one; but then he will be six times as long about it, that is, twelve minutes: thus the work is performed in the same time, whether the mechanical power is used or not. But the convenience gained by the power is very great; for if the six beams are joined in one, they may be raised by the tackle, though it would be impossible to move them by the unassisted strength of one man.

Consequently, if by any power you are able to raise a pound with a given velocity, it will be impossible, by the help of any machine, to raise two pounds with the same velocity; yet, by the assistance of a machine, you may raise two pounds with half that velocity, or even one thousand with the thousandth part of that velocity; but still there is no greater quantity of motion produced, when a thousand pounds are moved, than when one pound is moved; the thousand pounds moving proportionally slower.

No real gain of force is, therefore, obtained by mechanical contrivances; on the contrary, from friction, and other causes, force is always lost; but by machines we are able to give a more convenient direction to the moving power, and to apply its action at some distance from the body to be moved, which is a circumstance of infinite importance. By machines also, we can so modify the energy of the moving power, as to obtain effects which it could not produce without this modification.

In machines composed of several of the mechanical powers, the power will be to the weight, when they are in equilibrio, in a proportion formed by the multiplication of the several proportions which the power bears to the weight in every separate mechanical power of which the machine consists.

Suppose a machine, for instance, composed of the axle in the wheel, and a pulley; let the axle and wheel be such, that a power consisting of one-sixth of the weight will balance it; and let the pulleys be such, that by means of them alone, a power equal to one-fourth of the weight would support it: then, by means of the axle in the wheel, and the pulleys combined, a power equal to one-fourth of one-sixth, that is, $\frac{1}{24}$ of the weight, will be in equilibrio with it.

In contriving machines, simplicity ought particularly to be attended to; for a complicated machine is not only more expensive, and more apt to be out of order, but there is also a greater degree of friction, in proportion to the number of rubbing parts.

Whatever may be the construction of a machine, its power will always be in proportion to the velocity of the power to the weight; and so that this is obtained in the greatest degree that circumstances will admit, or that are necessary, then the fewer parts the better.

It is evident, from the principles already laid down, that the velocity of a wheel is to that of a pinion, or smaller wheel which is driven by it, in proportion to the diameter, circumference, or number of teeth in the pinion to that of the wheel. Thus, if the number of teeth in a wheel are 60, and those of the pinion 5, then the pinion will go 12 times round for once of the wheel, because 60, divided by 5, gives 12 for a quotient.

Hence, if you have any number of wheels acting on so many pinions, you must divide the product of the teeth in the wheels by those in the pinions; and the quotient will give the number of turns of the last pinion in one turn of the first wheel. Thus, if a wheel A (fig. 27) of 48, acts on a pinion B of 8, on whose axis there is a wheel C of 40, driving a pinion D of 6, carrying a wheel E of 36, which moves a pinion F of 6, carrying an index; then the number of turns made by the index, will be found in this manner: $\frac{48}{8} \times \frac{40}{6} \times \frac{36}{6} = \frac{69120}{288} = 240$, the number of turns which the index will make while the wheel A goes once round.

Any number of teeth on the wheels and pinions having the same ratio, will give the same number of revolutions to an axis: thus, $\frac{64}{10} \times \frac{50}{8} \times \frac{36}{6} = \frac{115200}{480} = 240$, as before. It therefore depends upon the skill of the engineer, or mechanic, to determine what numbers will best suit his design.

It is evident, that the same motion may be performed, either by one wheel and pinion, or by many wheels and pinions, provided the number of turns of all the wheels bear the same proportion to all the pinions which that one wheel bears to its pinion.

When a wheel is moved immediately by the power, it is called a leader; and if there is another wheel on the same axis, it is called the follower. Thus A, being moved immediately by the power, is to be considered as a leader, and B as a follower; the wheel C being driven by B, becomes a leader, and D a follower; E (fig. 28) is a leader, and the cylinder F may be considered as a follower.

Sometimes the same wheel acts both as a leader and a follower; as in fig. 29, where B is moved by A, and consequently is a follower, while, as it drives C, it is also a leader. Therefore, as to multiply both the divisors and dividend by the same number does not alter the quotient; in mechanical calculations, every wheel that is both a leader and a follower, may be entirely omitted.

The power of a machine is not at all altered by the size of the wheels, provided the proportions to each other are the same.

On the application of men and horses, as moving powers in machinery, &c. A horse draws with the greatest advantage, when the line of draught is not level with his breast, but inclines upwards, making a small angle with the horizontal plane.

A horse drawing a weight over a single pulley, can draw 200lb. for eight hours a day, and walking at the rate of 2½ miles in an hour, which is about 3⅔ feet in a second; and if the same horse be made to draw 240lb., he can work but six hours a day, and cannot go quite so fast. To this may be referred the working of horses in all sorts of mills and water-works; where we ought to know as near as we can, how much we make every horse draw, that we may judge of what the effect will be, when proper allowance shall have been made for all the frictions and hindrances, before we cause any machine to be erected.

When a horse draws in a mill, or gin of any kind, great care should be taken that the horse-walk, or circle in which he moves, be large enough in diameter, otherwise the horse cannot exert all his strength; for, in a small circle, the tangent (in which the horse draws) deviates more from the circle in which the horse is obliged to go, than in a larger circle. The horse-walk should not be less than 40 feet in diameter, when there is room for it. In a walk of 19 feet diameter, it has been calculated that a horse loses two-fifths of his strength.

The worst way of applying the force of a horse, is to make him carry or draw up hill; for, if the hill is steep, three men will do more than a horse; each man loaded with 100lb. will move up faster than a horse that is loaded with 300lb. This is owing to the position of the parts of a man's body, which are better adapted for climbing than those of a horse.

As a horse, from the structure of his body, can exert most strength in drawing almost horizontally in a straight line, a man exerts the least strength that way; as for example: if a man weighing 140lb., walking by a river or canal side, draws along a boat, or barge, by means of a rope coming over his shoulders, or otherwise fastened to his body, he cannot draw above 27lb., or about $\frac{1}{27}$ of what a horse can draw in that case. Five men are about equal in strength to one horse, and can with the same ease push round the horizontal beam in a 40-foot walk; but three of the same men will push round a beam in a 19-foot walk, which a horse (otherwise equal to five men) can but draw round.

A man turning a horizontal windlass by a handle, or winch, should not have above 30lb. weight acting against him, if he is to work ten hours a day, and raise the weight at the rate of three feet and a half in a second. This supposes, however, that the semidiameter of the windlass is equal to the distance from the centre to the elbow of the handle; for if there is a mechanical advantage, as there usually is, by having the diameter of the axle, on which the rope winds, four or five times less than the diameter of the circle described by the hand, then may the weight (taking in also the resistance, on account of the friction and stiffness of the rope) be four or five times greater than 30lb.; that is, so much as it rises slower than the hand moves.

MECONIUM, in pharmacy, the extract of English poppies. Meconium has all the virtues of the foreign opium, but in a somewhat lower degree.

MEDAL denotes a piece of metal in the form of coin, such as was either current money among the antients, or struck on any particular occasion to preserve the portrait of some great person, or the memory of some illustrious action, to posterity. Its etymology is probably of little consequence, though the best authorities give it from "metallum."

To enlarge on the utility of medals in the sciences, were needless. As historical documents, they form the principal evidence we can have of the veracity of old historians. In some few instances they correct the names of sovereigns; and in a great many, illustrate the chronology of reigns. By their assistance the geographer has sometimes been enabled to determine the situation of a town whose name alone has reached us. To the naturalist they afford the only proofs of the knowledge which the ancients had of certain plants and animals; and they sometimes preserve delineations of buildings for the architect, of which not even a ruin is, at this day, standing. The connection of medals and poetry has been treated at considerable length by Mr. Addison. To the connoisseur they are absolutely necessary, as they enable him to appropriate the busts and portraits of antiquity. And the scholar need hardly be reminded that they have contributed in no small degree to the elucidation of obscure passages in antient authors. The alto-relievo of the Greek coins is one of the best schools of study for the sculptor.

The study of medals, perhaps, is not of very antient date. The preservation of the Greek coins among their choicest treasure, is said to have been one of those marks of due respect which the Romans shewed the Greeks: but the knowledge of medals in series does not seem to have formed a distinct branch, either of study or entertainment, till the revival of literature in Europe. Petrarch is related to have been one of the first who began to study the medallic science. Alphonso, king of Arragon, formed another collection. And a third was placed by Cosmo de Medici among the curiosities in the Museum at Florence.

In this country, though we know of the existence of no cabinet before the time of Camden, it may be fair to suppose that the knowledge of coins and medals was introduced from Italy. The "Britannia" was the first work in which engravings of them were produced: and Speed's Chronicle, which soon followed it, was illustrated with coins from the collection of sir Robert Cotton. Henry prince of Wales was one of the first who had a *rich* cabinet; and he bequeathed it at his death to Charles. The most considerable of our other early collectors were, archbishop Laud, lord Arundel, and Mr. Selden. Oliver Cromwell, we are told, had a small collection; and the cabinet of Charles the Second is mentioned by Vaillant.

In the article here presented to the reader's notice, we shall give first a brief account of the coins of the most antient nations which are still extant; reserving only the Greek and Roman, which are the most interesting of all coins, for a more extended view; adding, at the close, a particular though condensed history of the coins and coinage of England. For the first part, as well as for the Greek and Roman coins, we have relied principally on the authority of Mr. Pinkerton. For the last, all the best writers have been consulted.

In what country coinage originated is uncertain, though the Greeks have the fairest claim to the invention. Homer, indeed, makes no mention of money; and even in Scripture we find weight alone used in the estimation of metals. The Hebrew shekels, and the brass coins with Samaritan characters, are thought to be, most of them, later than the Christian æra, and generally the fabrication of modern Jews. A sprig on one side, and a vase upon the other, is their general impression.

The Assyrians, the Medes, and the early inhabitants of Egypt, appear to have been totally ignorant of coined money. Nor was it used by the Phœnicians till after the Greeks had set the example. "Upon the whole," says Mr. Pinkerton, "the Lydian coins seem the most antient of Asia: they are without legends, but have all the rude appearance of antiquity." The next are the Persian, which are well known from the archer on them; and from Mithras the Persian deity, the dress of the princes, and other marks. One of the Darics, coined about five hundred years before the Christian æra, is engraved in the first plate of the Numismata Pembrochiana. "All the real Darics," says Mr. Pinkerton, "are gold; the silver coins with the archer are later, and never were called Darics." Of the latter, a great many are preserved in the cabinet of Dr. Hunter. A second series of Persian coins begins with Artaxares, or Artaxerxes, who overthrew the Parthian monarchy about the year 210, and ends with the year 636, when Persia was conquered by the Saracens. These are large and thin, with the king's bust on one side, and usually the altar of Mithras on the other; the former accompanied by Persian letters. Four of them are engraved in the Numismata Pembrochiana, and six others on a separate plate from the cabinet of the late Mr. Duane. The Phœnician and Punic, with the Palmyrene and the Etruscan coins, and perhaps the early Spanish, make up the list of the more antient. The early Gaulish coins are too rude and indistinct for explanation.

The description of the Greek coins it is probable will be best prefaced by a few remarks on their original value. A knowledge of this subject is not more necessary to the collector than the classical scholar. The first shape, says Mr. Pinkerton, in which money appeared, it is well known, was that of pieces of metal without stated form or impression, but merely regulated to a certain weight. For weight was the grand standard of antient coinage. In Greece large sums were referred to so many mnæ or minæ; and the yet larger denomination of so many talents. The mina is thought to have contained 100 drachmæ, and the talent 60 minæ. Such at least was the measure of Athens. A list of the value of the other antient talents has been given by Dr. Arbuthnot: its authority, however, has been questioned, and the difficulty of applying it to antient coinage seems extremely great.

The leading denomination of the Greek silver money was the drachma, or eighth part of an ounce, of which Mr. Pinkerton describes the medial value to be ninepence sterling: the didrachm, tridrachm, and tetradrachm, explain themselves, except the tetradrachm of the Ægineau standard, which was valued at five shillings. This last was the largest form of the Greek silver coins. The silver divisions of the drachma were the tetrobolion, the hemidrachm or tribolion, the diobolion, the obolus, the hemiobolion, the tetrabolion, and dichalcos; the first of the value of sixpence, the last of a farthing and a half. Of the distinct names by which many of these coins were called among the different states, our intelligence is partial; nor are such names of consequence.

The next Greek coinage, in point of antiquity, is that of copper, which is said not to have been introduced till four hundred and four years before the Christian æra. The first copper coin of Greece was the chalcos, of which two went to the quarter of the silver obolus. In days of poverty, however, even this was divided by different states into different portions, which were called Λεπτα, or little coins. The lepton, dilepton, and tetralepton, were the divisions of the chalcos, the smaller of which, from their perishable size, are very rare. Such were the brass coins of Greece previous to the subjection of that country to the Roman empire.

The earliest of the gold coins of Greece are those of Philip of Macedon, although they were struck in Sicily considerably earlier. Philip, having conquered the city Crenides, on the confines of Thrace, found gold-mines in its neighbourhood, formerly ill explored, and of small produce. From this gold he first struck the coins called Philippi, because of his portrait which appears on them. The Philippi it should seem were didrachms, the form most universal in the antient coinages of gold; and at their first appearance went for 20 silver drachmæ, but in latter times for 25 Greek drachmæ or Roman denarii. The Philippus was also called Χρυσος. There were likewise the ημιχρυσος and the τεταρτοχρυσος, with gold coins of Cyrene, which could not have gone for more than two drachmas of silver. There were also the Δι χρυσος and the Τετραςηρ, or quadruple Χρυσος; the former worth about two, and the latter worth about four pounds of our money.

The original value of the Roman coins is a subject still more intricate and extensive. As in Greece, the first estimation of their money was by weight; though copper, not silver, was the first medium of coinage. The first Roman coinage, according to Mr. Pinkerton, was in the reign of Servius Tullus, about the year 460 before the common æra, and was confined to the as or æs libralis, or piece of brass only, which was stamped with the two-faced head of Janus on the one side, and the prow of a ship on the other; though Mr. Pinkerton afterward thinks it probable that the very first Roman ases of Tullus had the figure of a bull, ram, or other species of cattle. However this may be, parts of the as were very early given in proportion of weight and value: such were the semis or half, the triens, the quadrans, the sextans, and the uncia. After a certain period, the as, though still called libra, fell to two ounces; and as it fell in weight, larger denominations were coined. Such were the bissus or dupondius, the tressis, the quadrussis, and even the decussis, or piece of ten ases in copper.

When the Romans began, by intercourse with Greece, to imbibe the arts of elegance, a variety of types appeared upon the parts of the as, and at length upon the as itself; though these, it is believed, are not seen till near the time of Sylla. Dupondii, or double ases, were also coined in the later period of the commonwealth, as in the former; together with the sestercii ærei, which came in place of the quadrusses. It must also be observed that the Romans, in some instances, accommodated their coins to the country in which their army was stationed; so that it is from the coins struck at Rome only that the coinage can be adjusted.

The largest of the imperial brass coins, according to our author, was the sestercius, worth about twopence English; no sensible diminution of which from its first weight of an ounce took place till the reign of Alexander Severus, when it lost upwards of a sixth. In the time of the Philippi, it was still more reduced; and under Trajanus Decius it had lost near a half. He was the first prince who seems to have coined double sestercii, or quinarii of brass, for such are the common medallions inscribed FELICITAS SAECVLI, or VICTORIA AVG., which just weigh double his sestercii, and little more than the sestercii of the early emperors. From Trebonianus Gallus down to Gallienus, when what is called the first brass ceases, the sestercius does not weigh above one-third of an ounce: any larger are double sestercii, or medallions struck upon uncommon occasions. After Gallienus, the sestercius totally vanishes. Under Valerian and Gallienus, a new coinage appears of what were called denarii æris, or Philippei æria of copper washed with silver. In the reign of Diocletian, the follis supplied the place of the sestercius; and soon after we find the denarius æreus dropped for ever. Such was the progress of the largest form of the imperial brass coin of Rome.

The dupondius, being half the sestercius, was the next in value. Prior to Augustus, it seems to have been commonly struck in copper; though after his time it was struck in yellow brass. It kept pace with the sestercius in all its stages.

The imperial as or assarium is the next coin. It began to be called assarium as soon as its size was reduced to half an ounce, and, like the dupondius, diminished gradually in its form, till at the end of Gallienus's reign it became what is called small brass. The parts of the as, says Mr. Pinkerton, in the imperial times, are, generally speaking, very rare. However, of Nero, there are the semis, triens, quadrans, sextans, and uncia, being all the parts; and of Domitian there are the same.

From Pertinax down to Gallienus, there is no small brass save of Trajanus Decius. With Gallienus it becomes extremely common. Toward the end of his reign the assaria were diminishing to a still less size. Farther we shall not trace this branch of the coinage.

The silver coinage of Rome is supposed first to have taken place about 266 years before the christian æra. The most antient denarii are those on which no inscription, save the word ROMA, appears: and at that time the denarius seems to have gone for ten ases; though it was afterward raised to sixteen, till the time of Gallienus. Under Caracalla, when the silver coinage was debased, denarii were struck of two sizes; the larger bearing an increase of value by a third. Both, however, lessened by degrees till after Gordian III. when the smaller totally vanished, and the larger alone remained. The latter, in the time of Gallienus, was the sole denarius of silver, and probably gave rise to the denarii æreì, which have been already mentioned. Such was the silver coinage till the time of Constantine the First, when the milliarensis was introduced, weighing about 70 grains, and answering in worth to our shilling. The denarii or argentei were, however, still coined, and were the money most common in currency.

Of the smaller silver coins of Rome, two only remain to be mentioned, the quinarii or pieces of five ases, and the sestercii of silver, which seem to have been coined down to Augustus.

Gold, we are informed by Pliny, was first coined at Rome in the 204th year before the present æra; and his account of the diminution in weight which marked the progress of its coinage, is singularly corroborated by such coins as have come down to us. The scruple, he says, went for 20 sesterces. "It was afterward thought proper to coin 40 pieces out of the pound of gold. And our princes have by degrees diminished their weight to 45 in the pound." Till Sylla's time, the aureus continued at 30 denarii; it afterwards fell to 20; though both under Claudius and Severus we find it at 25. Constantine the First, instead of the aureus, gave the solidus, of six in the ounce of gold, one of which answered to 14 of the milliarenses. The solidus continued of the very same standard to the close of the Byzantine empire.

Of the portraits which are to be found on coins, those of the kings of Macedon have the first rank, as their coins have the greatest antiquity of any yet discovered on which portraits are found. Alexander I. begins the series, who reigned 501 years before the christian æra. Then follow the kings and queens of Sicily, Caria, Cyprus, Pontus, Egypt, Syria, Thrace, Bithynia, &c. extending in series from the time of Alexander the Great to the birth of Christ, comprising a period of about 330 years. In this class are placed the beautiful coins of the Seleucidæ. The last series of antient kings goes down to the fourth century, including those of Mauritania and Judea; and finishing the series of the portraits of kings found on medals struck with Grecian characters.

The Roman emperors present a most distinct series from Julius to a later period than the destruction of Rome by the Goths.

The kings, upon Greek coins, have generally the diadem, without any other ornament, usually with a side face, and almost always in very high relief; though several, particularly the beautiful gold coin of Ptolemy Philadelphus, others of Antony and Cleopatra, &c. have more portraits than one upon them. The chief ornament of the portraits is the diadem or vitta. The radiated crown, a mark of deification, on the posthumous coins of Augustus, was, in a little more than a century after, put upon most of the emperors' heads in their several medals. The crown of laurel is continually seen: and Agrippa appears not only with the rostral but the mural crown. The successors of Alexander assumed, by way of distinction, different symbols of deity on the busts of their medals. A few instances also occur, among the Roman coins, of the helmet.

The reverses of medals, both among the Greeks and Romans, were of infinite variety. They contain figures of deities at whole length with their attributes and symbols; public buildings and diversons; allegorical representations; ceremonies; historical and private events; figures of antient statues; subjects of natural history; magistracies, &c. The reverses of the Roman coins have more of art and design than the Greek, though the latter have more exquisite relief. In the very antient coins no reverse is found, and of the antient Greek reverses some are in intaglio. The figures of deities and personifications on the Roman coins, are commonly attended with the names: as, the figure of Virtue with VIRTVS AVGVSTI: but on the reverse of the Greek coins the figure is only accompanied by some certain symbol; as Ceres with her wheaten garland, Mars with his armour, or Mercury with his caduceus. The anchor on Seleucian coins is the mark of Antioch; the owl, of Athens; the labyrinth, of Crete; the horse, of Thessaly; and so on.

Of the legends, the early Greek coins usually contain the name or the initials of the city they belong to; or the name, the first character of it, or the monogram, of the prince. The earliest coins of Athens have only ΑΘΕ, money of Athens: ΣΥ, of Sybasis; ΜΑΣ, of Massilia. ΣΥΡΑΚΟΥΣΙΩΝ occurs at full length, as well as ΦΙΛΙΠΠΟΣ for Philip of Macedon. And though in aftertimes the names of princes were accompanied by modest adjuncts, there were others that were not a little proud. Of the former were ΔΙΚΑΙΟΥ, ΕΥΣΕΒΟΥΣ, ΦΙΛΕΛΛΗΝΟΣ of the latter, ΘΕΟΠΑΤΟΡΟΣ, ΒΑΣΙΛΕΩΣ ΒΑΣΙΛΕΩΝ, &c.

After the Roman empire had swallowed up the Grecian, the legends on Greek coins became as remarkable for length as they had before been for brevity. The Greek imperial coins have a great variety in their legends. Nor are many of the reverses wanting in adulation. The legends of the Roman imperial coins are still more deservedly celebrated for their beautiful simplicity. IVDEA CAPTA and ASIA SUBACTA are sufficient instances.

Of the pieces produced by the antient mints, there were some of a size which shewed them evidently to have been intended for something else than circulation. Medallions were occasionally presented by the emperor to his friends; and sometimes by the mintmaster to the emperor as specimens of workmanship. These are usually known by their weight, which is far greater than that of the acknowledged money. Both the Greek and Roman medallions appear to have been principally struck in the imperial periods. Till the time of Hadrian they are rare. For a more full account of them, we refer to the work of Mr. Pinkerton.

To dwell longer on the various types either of the Grecian or the Roman coins, would be superfluous. Their curiosity and elegance are infinite. The regal coins of Greece are interesting from their portraits; the coins of cities, from their importance to geography. On the consular coins of Rome, the names and titles of the consuls do not appear till toward the close of the series: the brass consular coins are uninteresting. The imperial brass is of three sizes, large, middle, and small; the first forming a series of the greatest beauty. The imperial silver coins are numerous; the gold, of wonderful perfection. For the different abbreviations which occur both upon the Greek and Roman coins, we shall refer to the Tables selected by Mr. Pinkerton, as it would be impossible, in so concise a work as this, to give every information which the collector might require. The best works upon the Greek and Roman coins are probably these: Froelich's Notitia Elementaris; Neuman's Populi & Reges inediti; the Works of Pellerin; the Nummi populorum et urbium Magnæ Græciæ, by Dr. Combe; Havercamp on the Consular Coins; and the Roman Imperial, by Vaillant, edition 1745, by Valdini, with the Supplement by Kehl.

Of the early British coins, previous to the arrival of the Romans, we know but little. They were probably like the antient Gaulish, rudely ornamented, and without inscriptions. Those which we usually call British, were evidently the work of Roman moneyers. Those with CVNO on one side, and CAMV on the other, are usually ascribed to Cunobelin, the king of the Trinobantes. There is also one which has a bull on the obverse, with V.E.R.V.L.A.M.I.O. for the legend, apparently struck at Verulam. The meaning of *tascia*, which is common both to the Gallic and the British coins, wants explanation.

Of the coins of the Saxon heptarchy, there are but two descriptions: the sceatta, or penny, and the styca; the latter of which seems to have been principally confined to the kingdom of Northumbria. Of the coins of the heptarchic princes, the series is very far from regular; and of one or two princes unique specimens only are known. Of the chief monarchs, Ethelbald and Edmund Ironside are the only two who break the series. Of their coinage we have no specimens. The obverses of all these bear merely the resemblance of a human bust; though the reverses are occasionally interesting. The inscriptions also are sometimes peculiar; and we have a few specimens in the ninth century of archiepiscopal coinage. The best guide to the collector of Anglo-Saxon coins will be found in the plates of Dr. Hickes's "Thesaurus;" their rarity and value may be learnt from the Essay we have so often quoted.

The two first kings after the Conquest coined only pennies, the types of which are different, though in point of weight and goodness they agree with the pennies of the Saxons: their weight was usually 22 grains and a half. The obverse represents sometimes the full, and sometimes the side face of the sovereign, with the name of the mint-master and town of mintage on the reverse. To pennies, Henry the First added halfpennies, though none of them have reached us. King Stephen's pennies were of the same value as those of his predecessors. There are also some extant, which have the name of Eustace on them, Stephen's son; and one occurs with the head and title of Henry bishop of Winchester, the king's base brother. Those of Stephen which have the banner, are the rarest. The pennies of Henry the Second are also scarce; of Richard the First we have only the French penny; and of John no money but what was coined in Ireland; though of the last there are not only pennies but halfpennies and farthings. The first coinage of Henry the Third had only on the obverse HENRICVS REX, and his pennies till within these 30 years were usually ascribed to Henry the Second. After his 32d year, we find III or TERCI added to the title. The pennies, halfpennies, and farthings of Edward the First are all common. Such pennies as have EDW. R.ANGL. DNS.HYB upon the obverse, are usually ascribed to Edward the First; those with EDWA. or EDWAR. to Edward the Second; and those with EDWARD or EDWARDVS to Edward the Third. This, however, is but conjecture. In the 18th of Edward the Third, the penny was brought down to 20 grains; and in his 27th year, we find groats and half-groats coined, in which the king's head was surrounded by a sort of double tressure. In the reign of Edward the Fourth, having previously sunk to 15, the penny fell to 12 grains. In Edward the Sixth's time, it was reduced to eight, and in Elizabeth's to little more than seven. Of the groats, Richard the Third is very rare. In 1503, Henry the Seventh coined the shilling or testoon: it resembled the groat, but was larger, and weighed no less than 144 troy-grains. The crown of silver was first struck by Henry VIII. and the half-crown, sixpence, and threepence, by Edward the Sixth. Elizabeth, in 1558, coined three-halfpenny, and in 1561, three-farthing pieces; but they were disused in 1582. Henry the Eighth was the first of our princes who debased the coinage; and in the earlier part of Edward the Sixth's reign, the practice was continued: but from the 43d of Elizabeth, 1601, the denomination, weight, and fineness of English silver, have remained the same. From 1561 to 1568, the money of Elizabeth was coined in a better taste, by means of a mill and screw; but the artist of this money being hanged for counterfeiting coins, the hammering system was again recurred to. Till the time of Charles the Second, we have little more of the milled money.

The design of a gold coinage appears to have been first formed by Henry the Third, the most particular account of which is to be found in lord Liverpool's Letter to the King. The piece ordered to be current was called a gold penny; but being of too great value for general circulation, it was in two or three years called in, and now but three specimens remain. In itself, the gold penny is a beautiful specimen of the coinage of the time. The obverse is much in the manner of the king's great seal, and the inscription Henricus Rex III.; on the reverse, the mint-master's name and place. The three known are all of different types: one reads LVND, another LVNDE, and the third LVNDEN. But it is from Edward the Third that the series of our gold coins commences. In 1344, he struck the florin, half, and quarter florin. The florin was current for six shillings, but was the same year succeeded by the noble, the value of which was half a mark. Henry the Fifth diminished the value of the noble; Henry the Sixth restored it to its size, and gave it the name of ryal; while Edward the Fourth, in 1465, supplanted it with the angel. Henry the Eighth, in 1523, added the gold crown and half crown at their present value: the sovereign of 22*s.* 6*d.*; the ryal at 11*s.* 3*d.*; the angel at 7*s.* 6*d.*; and the noble at its old value. In 1546, he coined sovereigns and half-sovereigns, the former to go at 20*s.* and the latter in proportion. Charles the Second, however, instead of the sovereign, introduced the guinea and half-guinea. George the First added the quarter-guinea. But though it was continued in the early part of the reign of his present majesty, the seven-shilling piece has been preferred.

The history of our copper coinage, the last in order of chronology, will be shorter. From the reign of Henry the Eighth till the close of queen Elizabeth's reign, the scarcity of silver farthings and halfpence gave rise to the introduction of tokens or pledges for money among tradesmen, many of which are undoubtedly alluded to in what has been said by Erasmus and other writers about leaden money. Elizabeth, it appears, would never hear of a copper coinage for the country: and though farthing tokens of copper were issued both by James and Charles the First, they were considered rather as pledges of government than legitimate money. The death of Charles the First put an effectual stop to their farther currency: and till 1672, the country again swarmed with town pieces and tradesmen's pledges; when, in the latter year, halfpence and farthings of copper were made public money, and the circulation of tokens forbidden. His present majesty has added two-penny pieces.

MEDEOLA, *climbing African asparagus*, a genus of the hexandria order, in the trigynia class of plants, and in the natural method ranking under the 11th order, sarmentaceæ. There is no calyx; the corolla is sexpartite and revoluted; the berry trispermous. Its characters are these: the flower has no empalement; it has six oblong oval petals, and six awl-shaped stamina terminated by incumbent summits; and three horned germina terminating the style; the germina afterward turn to a roundish trifid berry with three cells, each containing one heart-shaped seed. There are three species.

MEDICAGO, *snail-trefoil*, a genus of the decandria order, in the diadelphia class of plants, and in the natural method ranking under the 32d order, papilionaceæ. The legumen is compressed and screwed; the carina of the corolla luring down from the vexillum. There are 11 species, though only five are commonly cultivated in this country. They are low trailing plants, adorned with small yellow flowers, succeeded by small round snail-shaped fruit, which are downy, and armed with a few short spines. They are all easily propagated by seeds. The M. sativa or lucern, has been latterly much recommended as a green fodder for cattle, and has been cultivated by some farmers with success.

MEDICINE, is the art of preserving health, and of curing or alleviating disease. It is the same science in its application to animal, as agriculture to vegetable, life.

Origin and progress of medicine. "Medicina nusquam non est." This art arises out of the natural, as others more gradually and indirectly origiuate from the artificial and adventitious, wants of mankind. The exact period, however, in which medicine began to be formally practised as an art, or separately cultivated as a profession, has by no means been accurately ascertained. All the accounts which have been transmitted on this subject from a date prior to the time of Hippocrates, are either conjectural or fabulous. Hippocrates first effected a separation of medicine from philosophy and religion, and gave it the form of a distinct science: he has therefore been generally regarded by the moderns as the father of physic; and from his time the history of this science may be made with propriety to commence.

Hippocrates was a native of Greece. He was born in the island of Cos, and flourished about 400 years prior to the christian æra. Of his character as a physician, an estimate cannot, confessedly with much accuracy, be formed from his writings, or from those works which have been attributed to him, but which are generally regarded as in a great measure the inventions of his disciples and successors. "Hippocrates," says a modern author, "lived at too early a period to be acquainted with the collateral branches of science. He studied life and disease in the book of nature, and had the merit of an original observer." We do not, however, feel disposed with this author fully to acquit the "Coan sage of the many idle theories which have been imputed to him." It may well be conceived that he was influenced in his opinions on the cause of disease and on the nature of healing, if not by the splendid fictions of the Greek philosophy, by preconceived theory and vague conjecture. Indeed, the hypotheses contained in the reputed writings at least of Hippocrates, have been, with trivial modifications, the hypotheses of modern times; for in this author's pervading and presiding principle of nature, and in his attraction, depuration, decoction, and crisis of disease, may be traced the same mode of theorizing which has been adopted by later systematics.

The humoral pathology, and even the *vis naturæ medicatrix* of modern times, appear to be modifications or relics of Hippocratic reasoning.

The immediate successors of Hippocrates began to direct their researches into the auxiliary departments of medicine; and among these, Praxagoras, Chrysippus, Hirophilus, and Erasistratus, particularly the two last, made no inconsiderable discoveries (when we consider the scantiness of their materials) respecting the structure and functions of the human frame. It was about this period, according to Celsus, that the science was divided into the three distinct branches of dietetical, pharmaceutical, and chirurgical medicine—"una quæ victu, altera quæ medicamentis, tertia quæ manu mederetur." Shortly after the time of Herophilus, the medical world became divided into the two sects of empirics and dogmatists: the one, rejecting the reasoning and deriding the practice of their predecessors, affected to disregard all authority but that of experience; the other, retaining their faith in the scholastic philosophy of the times, and their conviction of the utility of physiological knowledge in detecting the causes and regulating the treatment of disease. The empiric sect was founded by Serapion of Alexandria, about 287 years before Christ.

The next revolution of importance in the medical art was occasioned by the introduction of the Epicurean philosophy into the schools of medicine. This was effected by Asclepiades, who was succeeded by Themison, the founder of the methodic sect, the members of which were equally hostile to the dogmatists and empirics. They discarded what they considered the occult reasoning of the former, and substituted in the room of the laborious observations of the latter, indications of treatments deduced from the analogy of diseases, or the mutual resemblance they bear to each other, "nullius causæ notitiam quicquam ad curationes pertinere; satisque esse quædam communæ morborum intueri methodici contendunt." *Celsus.* The most celebrated of Themison's followers were Thessalus, who flourished under the emperor Nero, and Soranus, a native of Ephesus, who lived during the time of the emperors Trajan and Adrian.

We have now arrived at a very conspicuous æra in the science of medicine. About the 131st year after Christ, in the reign of Adrian, lived the celebrated Galen, who was born at Pergamus. At this time the dogmatic, empiric, and methodic sects of physicians had each their advocates. The methodics, however, were held in greatest estimation. Galen undertook the reformation of medicine, and affected to restore the Hippocratic philosophy and practice. Instead, however, of abiding by the doctrines of his master, his systems were almost entirely of his own invention. "Philosophy and science had now made some advances; and from those sources Galen introduced many corruptions into medicine." Like Hippocrates, he supposed the existence of four humours, from the predominancy or deficiency of one or other of which the varieties of constitutions, and likewise the complexion and nature of disease, were conjectured to originate. These humours are, in the Galenic system, the blood, the phlegm, the yellow bile, and the black bile. He likewise establishes three distinct kinds of spirits—the natural, the vital, and the animal; the first of which he supposes to be a subtile vapour arising from the blood; this, conveyed to the heart, becomes, when conjoined to the air taken into the lungs, the vital spirits, which are changed into the animal kind in the brain. These three species of spirits our author imagined to serve as instruments to distinct faculties: the natural faculty, which he supposed to reside in the liver, and to preside over the nutrition, growth, and generation of the animal body; the vital faculty, which he lodged in the heart, and imagined that through the intervention of the arteries it communicated warmth and preserved life; while the animal faculty, according to Galen, has its seat in the brain, is the cause of motion and sensation, and presides over all the other faculties. The origin or principle of motion in these respective faculties, Galen, as well as Hippocrates, calls *nature.*

The authority of Galen, notwithstanding the tissue of extravagances and idle conjectures of which his systems were formed, continued to prevail until the downfal of the Roman empire. The seat of learning now became the theatre of war, and the arts of peace took refuge in the Eastern nations. The Arabian succeeded to the Greek and Roman physicians, and still further obscured the theories of medicine by the introduction of fresh absurdities. Anatomy was totally neglected, or at least not in any measure advanced, by the Saracens: they made some progress in the science of botany, and introduced several new drugs, principally of the aromatic kind, from the East, which retain still a place in the materia medicá.

The mention of a singular controversy which occurred among the Arabian physicians, may serve to indicate the complexion of the times in relation to the dogmas and practice of physic.

Hippocrates had directed that in pleurisy blood should be drawn from the arm of that side which might be principally affected. Some of the Arabians contended that it should be taken from the side opposite; and such was the medical ignorance and fanaticism of the age, that a decree was issued from the university of Salamanca in Spain, forbidding any one to pursue the practice of Hippocrates. The members of this university even endeavoured to procure an edict from the emperor Charles V. to confirm their authority, alleging, that the practice they opposed was no less pernicious to medicine than Luther's heresy had been to religion!

From the time of the decay of learning to the commencement of the 16th century, the history of medicine furnishes no particulars of interest. This last is the period which gave birth to the celebrated Paracelsus. Now, all the facts and doctrines of medicine came to be explained by, and founded upon, imaginary principles of chemical philosophy. The antient authors fell into disrepute; and the elements, qualities, and temperaments of the Greeks, were melted down and dissipated in the laboratory of the chemist. Fermentation, effervescence, ebullition, and deflagration with salts, sulphur, alkali, and mercury, came now to be familiarly, but without any precise signification, introduced among the terms of the medical art. With several, however, the Galenic philosophy continued to prevail.

In the year 1628, Dr. W. Harvey, of London, first demonstrated and communicated to the world the most important fact of the circulation of the blood. This discovery afforded a new foundation for the whole structure of medical and physiological reasoning. Even this, like all other improvements in science, and bold innovations of established doctrines, met with very cold encouragement by the contemporaries of Harvey. It is said that no physician or teacher of medicine, who had attained his 40th year, would subscribe to the fact; and that in thus conferring an incalculable benefit on the community, Harvey diminished his own contemporary reputation, and nearly lost his practice as a physician.

While some were industriously endeavouring to controvert the fact, others were busied in attempts to wrest the discovery from its author.

Servitus, a native of Spain, had, many years previous to the time of Harvey, published a Treatise on Medicine and Theology. In this work it is asserted, or rather perhaps conjectured, that the blood, by some unknown channel, passes from the pulmonary arteries into the veins. Even allowing that this intimation justly laid claim to the title of a discovery, it is merely a discovery of the passage of the blood through the lungs, and could in no measure interfere with the merit or be regarded as an anticipation of the Harveyian doctrine.

The period, however, had not yet arrived when a rational use was to be made of the important fact in question. As the alchemists had derided the Galenists, so the reasonings of the latter were now to give way to the mathematical sect of physicians, who by axioms, postulata, theorems, problems, experiments, and corollaries, ("a capite ad calcem armatos, et necem undique minitantes,") attempted to explain, in the most futile manner, the functions of life, and to regulate the remedial process.

The learned and industrious Boerhaave, of Leyden, whose name stands conspicuous in the annals of medicine, at length attempted to restore the authority of the antient writings; and by uniting the doctrines of Hippocrates with the philosophy of the times, he framed a theory of medicine upon the supposition of acrimony, lentor, and other changes in the circulating fluids. From these changes he inferred the origin of all disease; and the process of cure is, according to Boerhaave, either the process of correcting or expelling acrimony from the body, or the correction of morbid viscidity or tenuity in the humours. Boerhaave has, therefore, been considered the founder of the humoral pathology; a pathology which even to this day retains a material influence on the opinions, the phraseology, and the practice at least of the vulgar.

Contemporary with Boerhaave was the illustrious Hoffman, a German professor, and founder of a medical system. Dr. Staahl having first suggested, or rather borrowed from the antients, the idea of the rational soul of man governing and directing the whole economy of his body, and obviating the adverse tendency of noxious agents by exciting such actions in the system as are calculated to effect their expulsion, or destroy their malignity; Hoffman endeavoured to demonstrate, that the first operation of the causes creating disease was the production of universal atony or spasm in the primary moving powers of the system, and did not consist of changes produced either in the quantity or quality of the humours or fluids of the body, as taught by the celebrated Boerhaave.

The humoral, however, continued to prevail over the pathology of Hoffman; and Dr. Cullen informs us, that "when he came to take a professor's chair in the university of Edinburgh, he found the Boerhaavian system then in its full force." In framing a system of his own, Dr. Cullen reverted to the theory of Hoffman; and indeed the whole of his pathology, as far as it relates to leading systematic doctrines, is scarcely any thing more than an attempt to unite the hypothesis of Hoffman with the Stahlian principle of an intelligent, presiding, and preservative power.

We have thus rapidly conducted our readers over the ground of medical history, and have presented a faint outline of the prevailing systems of medical philosophy, from the time of the Grecian to the time of the "English Hippocrates;" to the period when the fanaticism and prejudice of system were shortly to give way before the precepts of genuine philosophy and temperate induction; when the medical science was to be established upon a new foundation; when chemistry was to undergo a reformation equally radical and important; when by consequence a new alliance was to be formed between these two sciences; when the language of metaphor and hypothesis was to be discarded from either; and when enquirers after truth were to be influenced and directed by the independant and invaluable maxim, "Nihil in intellectu quod non prius in sensu."

On nosology, or the classification of diseases. Dr. Sydenham was the first who proposed to adopt a division of diseases into class, order, and genus, upon similar principles with those of botanical arrangement. The idea has been followed out by several of Sydenham's successors, but by no means with that success which had been anticipated. The reason why nosologists have in some measure failed, is sufficiently obvious. While the objects of natural history possess a certain degree of uniformity, enabling the systematic to identify in a manner certain individuals, and thus to refer them to one class, scarcely any thing of this order is observed, or at least not sufficient to justify arrangement of the infinitely diversified phenomena of disease. For example: a certain series of symptoms shall present themselves during the life of an individual, which shall prove to have depended upon, or at least have been connected with, disordered condition of some particular organ. A careful register of such symptoms might be supposed to furnish the same guide to the pathologist and physician, as a recollection of the prominent character of a plant to the botanist or agriculturist. This, however, is by no means the case. Similar symptoms are not invariably characteristic of similar disorders. A cough may originate at one time from circumstances which would at another time suppress it. A catarrh of the nostrils will now be produced by a deficient, now by an excessive, action of precisely the same membrane. The generic terms then which are introduced into medicine, are extremely fallacious: they in fact convey no idea of the precise nature of that affection which they have been employed to indicate; and the difficulty is still greatly augmented when we recollect the endless diversities that must arise from the varied external circumstances, as affecting and modifying the constitutional character of the same individual.

A disease, then, as indicated by name, and described by signs, is in some measure an imaginary existence. Dr. Brown, the outline of whose doctrines is elsewhere exhibited (see the article BRUNONIAN SYSTEM), aware of the errors attached to nosology founded on symptoms, proposed to comprehend all morbid affections under the two leading divisions of diseases of increased and diminished excitement. Our author, however, in his opposition to particulars, went over to the other extreme of too indiscriminate and hasty generalization. The human frame is too complicated to admit of the simplification which Brown aimed at. His division is a guide to principle but not to practice.

A recent attempt has been made to include in one scheme both general principles and particular facts. This plan, however, notwithstanding the boldness of conception by which it was formed, and extraordinary ingenuity by which it has been executed, is defective. It rests upon a hypothetical, and therefore upon a sandy, foundation. Our readers who are acquainted at all with modern medicine, will be at no loss to conclude that we refer to the system of the late Dr. Darwin. By this author, excitability, which was left as an ultimate fact in the Brunonian theory, is attempted to be traced to its origin. The sensorial power, excitability, or spirit of animation, is conceived to be "a subtle fluid, residing in the brain and nerves, and liable to general or partial accumulation." The vital changes effected by the medium of this imaginary fluid, are, 1st, "Irritation, which is an exertion or change of some extreme part of the sensorium residing in the muscles or organs of sense, in consequence of the appulses of external bodies. 2. Sensation, an exertion or change of the central parts of the sensorium, or of the whole of it, beginning at some extreme parts of it, which reside in the muscles or organs of sense. 3. Volition is an exertion or change of the central parts of the sensorium, or of the whole of it, terminating in some extreme parts of it, which reside in the muscles or organs of sense. 4th. Association is an exertion or change of some extreme part of the sensorium, residing in the muscles or organs of sense, in consequence of some antecedent or attendant fibrous contractions."

With these assumptions as his guide, Dr. Darwin endeavours to penetrate deeper into the cause of disease than is allowed by a mere knowledge of the condition of the fibre. The powers of the sensorium are the proximate cause; the fibrous action, the excitement of Dr. Brown, the proximate effect; and hence, from an ingenious, but by no means satisfactory, statement of the mode in which excitations are produced, he treats of diseases as occasioned by the comparative redundancy or deficiency of the sensorial power of irritation, sensation, volition, or association.

It would carry us far away beyond our limits to pursue this theory through the minutiæ of its ramifications. Some opportunities will be afforded in the course of the present article to acknowledge the obligations which medicine is under to its ingenious framer. We shall here confine ourselves to the statement of what we consider fundamental objections to the doctrines, and, by implication, the nosology or arrangement of Zoonomia.

In the first place, it does not distinguish between cause and effect, between fibrous motion and its source. Secondly, it substitutes, like the antient systems, mere statements of phenomena for explication of their origin. Thirdly, and what is more immediately applicable to our present enquiry, it divides that which in its nature is indivisible.

Dr. Brown had defined excitement to be a certain state of fibrous action produced by the exciting powers acting upon the excitability. Dr. Darwin after him considers irritation or excitement as an exertion of the spirit of animation, exciting the fibres to contraction. Here we observe the want of precision alluded to, and the confusion originates from forsaking induction to embrace hypothesis. "On Dr. Darwin's principles the identical fibrous motion exists before the faculty of irritation can be exerted." The spirit of animation ought to have been stated as the unknown medium ("quo pacto adficiatur ignoratur") through which the excitement or irritation is produced.

Again, the sentient and fibrous changes which in the Darwinian system of life are thus connected, are not rendered more explicable by the intervention of a subtle fluid. The spirit of animation of Darwin, allowing its existence to be capable of proof, in no measure facilitates the conception of vital causation. As an exemplification of the last of the above objections, it may be urged, that when Dr. Darwin, in framing his classification, referred all morbid affection to the heads of irritation, sensation, volition, and association, he seems to have overlooked his former assumption, founded upon the inseparability and identity of the sensorial power or fluid, and not to have been aware he had already asserted that "propensity to action, whether it be called irritability, sensibility, voluntarity, or associability, is only another mode of expressing the quantity of sensorial power residing in the organ to be excited."

An increase then or diminution of one of these energies necessarily supposes an increase or diminution of all, "and the disorder of decreased irritability, ought also to be the disorder of decreased sensibility, voluntarity, and associability." The classification, then, is even in contradiction to the principles of Zoonomia. It is intricate and erroneous.

Perhaps the most consistent and comprehensive plan of arranging individual diseases would be that which, while it preserved the important fact in view, of the indivisibility of the living system, would take into its account the three leading, and in one sense separate, functions performed by the arterial, the nervous, and the glandular organization.

As approaching nearest to this plan, and likewise because it is in most general use in this country, at least as a text-book for teachers of medicine, we shall make use in the present article of the nosology of Dr. Cullen, requesting the reader to recollect the unavoidable objections which oppose themselves to all systems and all classifications of morbid affections.

The following are the classes, orders, and genera of Cullen, with the exception of the class locales, which relates to those disorders principally that come under the head of surgery.

TABLE OF CLASSIFICATION.

Class I. Pyrexiæ. A frequent pulse, succeeding to shivering or horror; increased heat; disturbed functions; prostration of strength.

Order I. *Febris.* Pyrexia, independant of local affection as its cause; languor, lassitude, and other signs of debility.

Sect. 1. *Intermittentes.* Fevers arising from the miasma of marshy grounds, with an evident remission, the returning fits being almost always ushered in by horror or trembling. One paroxysm only in the day.

Genera. Tertiana; quartana; quotidiana.

Sect. 2. *Continuæ.* Fevers without intermission, not occasioned by marsh miasma, attended with exacerbations and remissions, though not very perceptible.

Genera. Synocha; typhus; synochus.

Order II. *Phlegmasiæ.* Fever, accompanied by local inflammation or topical pain, lesion, or disturbance of the internal functions; sizy blood.

Genera. Phlogasis ophthalmia; phrenitis; cynanche; pneumonia carditis; peritonitis; gastritis; enteritis; hepatitis; splenitis; nephritis; cystitis; hysteritis; rheumatismus; odontalgia podagra; arthropuosis.

Order III. *Exanthemata.* Contagious diseases, which only affect once during life, commencing with fever, and succeeded by phlogosis or inflammatory eruptions on the skin.

Genera. Erysipelas; pestis; variola; varicella; rubeola miliaria; scarlatina; urticaria; pemphygus; apthæ.

Order IV. *Hemorrhagiæ.* Pyrexia; spontaneous discharge of blood; blood when drawn from a vein of a sizy appearance.

Genera. Epistasis; hemaptisis; hæmarrhois menarrhagia.

Order V. *Profluviæ.* Pyrexia; inordinate discharge, but not of blood.

Genera. Catarrh; dysenteria.

Class II. Neuroses. A lesion of sense and motion, without idiopathic pyrexia or local disorder.

Order I. *Comata.* A diminution of voluntary motion with sleep, or a deprivation of sense.

Genera. Apoplexia; paralysis.

Order II. *Adynamiæ.* Diminished voluntary motion, whether vital or natural.

Genera. Syncope; dyspepsia; hypochondriasis; chlorosis.

Order III. *Spasmi.* Irregular action of the muscular fibre.

Sect. 1. In the animal functions.

Genera. Tetanus; trismus; chorea; raphania; epilepsia.

Sect. 2. In the vital functions.

Genera. Palpitatio; asthma; dyspnæ; pertussis.

Sect. 3. In the natural functions.

Genera. Pyrosis; colica; cholera; diarrhœa; diabetes; hysteria; hydrophobia.

Order VI. *Vesaniæ.* Derangement of judgment, independantly of pyrexia or coma.

Genera. Amextia; melancholia; mania; oneirodynia.

Class III. Cachexiæ. A depraved habit of body, without idiopathic pyrexia or neurosis.

Order I. *Macores.* A wasting of the whole body.

Genera. Tabes; atrophia.

Order II. *Intumescentiæ.* A swelling of the whole or of the greatest part of the body.

Sect. 1. *Adiposæ.* Fatty swellings.

Genus. Polysarcia.

Sect. 2. *Flatulosæ.* Windy swellings.

Genera. Pneumatosis; tympanites; physometra.

Sect. 3. *Hydropes.* Watery swellings.

Anasarca; hydrocephalus; hydrorachitis; hydrothorax; ascites; hydrometra; hydrocele; physconia.

Order III. *Impetigines.* Cachexies, chiefly deforming the skin and external parts of the body.

Genera. Scrophula; syphilis; scorbutus; elephantiasis; lepra; frambæsia; trichoma; icterus.

CLASS I. ORDER I.—*Febris.*

What is fever? To this question it appears difficult to give a precise and satisfactory reply. It is observed by the author of Zoonomia, that "the term *fever* is given to a collection of morbid symptoms, which are indeed so many distinct diseases that sometimes appear together, and sometimes separate; hence it has no determinate meaning, except it signifies simply a quick pulse, which continues for some hours;" in which sense Dr. Darwin employs the word throughout his ingenious work.

On this head, however, we differ in opinion with the author just mentioned. An increased action of the sanguiferous system shall be induced sometimes by, and at other times independant of, a diseased irritation, without being accompanied with other peculiar feelings, which, not restricting ourselves to the etymological signification of the term *fever*, we purpose regarding as necessary constituents of this, as a distinct malady.

In every proper fever, there is a feeling of depressed power, which essentially differs from actual debility. "A diminution of strength in the animal functions," which constitutes part of Dr. Cullen's definition of the febrile state, is scarcely characteristic of the condition to which we allude. It is a feeling with which every one is more or less familiar, and appears to indicate rather obstructed than exhausted strength. Dr. Rush endeavours to illustrate this necessary constituent of genuine fever as a distinct expression from simple irritation of the blood-vessels on the one hand, and mere debility on the other, by comparing it with the smothered sound which may be supposed to be emitted from a musical instrument, provided a heavy weight were applied to the chords; which ought to be suffered to vibrate freely and without obstruction, in order to produce a full and harmonious sound. An illustration of a similar nature is likewise employed by Dr. Jackson.

Dr. Brown defines fever, "an asthenic disease that disturbs the pulse." In this, however, there is the same want of distinction which we have just complained of in the definition of Dr. Cullen. Asthenic diseases are diseases of deficient excitement; but in fevers we have an interruption rather than diminution of power. The faculties are locked up, not lost.

Of the phenomena of fever. Dr. Cullen very properly selects the more ordinary circumstances that present themselves in the course of an attack of intermittent fever, as an example of what occurs with more or less regularity in every case of genuine febrile disorder.

"The following," he says, "are to be observed in such a paroxysm. The person is affected with languor or sense of debility, a sluggishness in motion, and some uneasiness in exerting it, with frequent yawning and stretching. At the same time the face and extremities become pale, the features shrink, the bulk of every external part is diminished, and the skin over the whole body appears constricted as if cold had been applied to it. At the coming on of these symptoms, some coldness of the extremities, though little taken notice of by the patient, may be perceived by another person. At length the patient himself feels a sensation of cold, commonly first in his back, but then passing over his whole body; and now his skin feels warm to another person. The patient's sense of cold increasing, produces a tremor in all his limbs, with frequent successions or rigors in the trunk of the body. When this sense of cold and its effects have continued for some time, they become less violent, and are alternated with warm flushings. By degrees the cold goes off entirely; and a heat greater than natural prevails and continues over the whole body. With this heat the colour of the skin returns, and a preternatural redness appears especially in the face. Whilst the heat and redness come on, the skin is relaxed and smooth, but for some time continues dry. The features of the face and other parts of the body, recover their usual size, and become even more turgid. When the heat, redness, and turgescence, have increased and continued for some time, a moisture appears on the forehead, and by degrees becomes a sweat, which gradually extends downwards over the whole body. As this sweat continues to flow, the heat of the body abates; the sweat, after continuing for some time, gradually ceases, the body returns to its usual temperature, and most of the functions are restored to their ordinary state.

Species of fevers. The general division of systematics is into continued and intermittent. The very correct description above given answers, as we have stated, to a single paroxysm or fit of fever. It is not however often that the disorder terminates with the decline of the paroxysm. In the course of a certain time it is renewed; and according to the suddenness or tardiness of the paroxysm's recurrence, the fever is called continued, remittent, or intermittent. Sometimes, indeed, the disordered actions recur with such celerity, that the fever appears to be one continuous series; "the remission is inconsiderable, is perhaps without sweat, and the returning paroxysm is not marked by the usual symptoms of a cold stage, but chiefly by the exacerbation or aggravation of the hot one." The disease in this last case is considered as a continued fever; in which, however, there is, though not the distinct stages of an intermittent, almost invariably, especially in the earlier periods, a diurnal remission and recurrence of paroxysm. Of intermittent fevers, the paroxysms, such as we have just described, are always finished in less than 24 hours, and most frequently are not extended to nearly this time.

We are then furnished with a natural division of fever into intermittent and continued, which however have many circumstances in common, and often pass into each other; thus, what is termed in the schools a quartan intermittent, formed by an interval of 72 hours from the commencement of one to the commencement of another paroxysm, will in its course become a tertian ague, with only 48 hours of interval: this again shall fall into a quotidian, characterized by an interval of only 24 hours. A quotidian shall pass into the state of a remittent, and this last be converted into a true continued fever.

Besides, however, this leading distinction of fever, from the times of the recurrence of the fits, we have many others arising from the nature of the constitution of the individuals attacked, the prevailing condition of the atmosphere, and other extraneous circumstances, and likewise (what is ascertained however with less exactness) the specific difference of the exciting cause; thus, common fever has sometimes the inflammatory, at others the typhoid, character. Thus are presented the bilious remittent fever of damp and warm climates, the yellow fever of the West India islands, the jail fever of crowded prisons, and the plague in Eastern countries.

On Cullen's genera. It will be perceived that under the appellation of fever we confine ourselves to the consideration of what has been by way of distinction termed simple fever, and perhaps with propriety regarded by Mr. Wilson as "the only general disease," other diseases being either local, or general and local. Thus the sensitive irritated fever of Darwin, which forms principally the phlegmasia of Cullen, is a disorder either symptomatic of, or at least supported by, local irritation.

The genera of Dr. Cullen of continued fever, are,

1. *Synocha.* "Great heat, pulse frequent, strong, and hard; high-coloured urine, the functions of the sensorium not much impaired." Such character, however, does not answer to any case of simple fever; it is the definition of what Dr. Brown calls the sthenic, which is opposed to the true febrile state.

2. *Typhus.* "A contagious disease, the heat not much increased, pulse frequent, small, and weak; urine little changed, sense much impaired, and the strength greatly diminished." This definition approaches nearest to the more usual form of fever in this country. That part of the definition, however, is extremely defective which describes the heat as not much increased.

3. *Synochus.* This is made by Cullen a kind of intermediate disease between synocha and typhus.

Exciting causes of fever. On this subject the most opposite opinions prevail. It is imagined by some, that no case of genuine fever, beyond those ephemeral irritations which are of daily occurrence, can possibly originate without the previous application, either through the medium of the lungs, or the surface of the body, of a certain something generated in the system of another individual in the course of the same disease. Others infer, from the daily observation of febrile diseases where no communication with the sick can be traced or suspected, that although the febrifacient matter just spoken of be in many, it is not in all instances the cause of fever; that cold, damp, heat, putrid exhalations whether animal or vegetable, insufficient ventilation, the depressing passions, &c. are all, either singly or in conjunction, capable, under some circumstances, not merely of predisposing to, but of actually engendering, proper fever. Lastly, there are some who consider contagion, or the generation in fever of specific febrifacient matter, as totally imaginary; and conceive in instances where fever has spread by communication, that either certain undetected conditions in the air, or the confined effluvia of animal excretions accumulated by want of cleanliness and ventilation, with other circumstances, are causes sufficiently adequate to produce the affection, without supposing the agency of a specific and occult power. "It is from nastiness," says one of the most celebrated of the anticontagionists, "degenerating into infection by chemical changes, that the bodies, clothes, beds, and apartments, of the poor in Great Britain, derive their poisonous, their pestilential charge. By a common putrefactive process, this *septic venom* is formed, and derives none of its qualities from pulsating arteries or glands. Away then with this preposterous phrase, 'from the poison engendered by septic processes.' Let human contagion for the future mean nothing but small-pox, vaccinia, and the kindred forms of morbid secretions." (Dr. Rush.)

Notwithstanding, however, the circumstances here pointed out and rested upon, we conceive the general facts to be in favour of poison engendered, independant of mere putrefaction or filth; and we shall shortly state the grounds upon which our opinion is established, when upon the subject of preventing the spread of fever. That contagion, however, is absolutely requisite to the production of this disorder, in every instance, does not seem an opinion authorized by facts, although it must be admitted that the negative is incapable of proof; for when we refer to its generation from mere filth and sloth, under the circumstances just mentioned from Dr. Rush, it may be replied, that contagion in such cases might have been in some manner conveyed without suspicion, and that the situation of the recipient constituted merely a predisposition to suffer from its application.

A contest has likewise arisen respecting the production of intermittent as well as continued fever. Intermittent fevers are observed to prevail especially in situations the soil of which is marshy: on this account it has been imagined, that they are invariably consequent upon a certain taint or miasma arising from moist ground. "The similarity of the climate, season, and soil, in the different countries in which intermittents arise, and the similarity of the disease, though arising in different regions, concur in proving that there is one common cause of these diseases, and that this is the marsh miasma." (Cullen.) Dr. Brown and others have contended, that the noxious influence of cold or of heat, "when the common asthenic noxious powers accompany either," are sufficient to occasion genuine intermittent. It however appears an established principle, that intermittent fevers are most frequently the offspring of poison arising from marshes or moist ground. That other causes act in conjunction, and augment the predisposition, is likewise an established fact; for the agues of marshy countries occur most abundantly at cold seasons which have succeeded hot ones, and especially amongst those whose diet has been innutritious and unstimulating. It is also beyond dispute that mere cold or poor living will induce ague after the habit has been once established.

Proximate cause of fever. On this subject the following errors appear to have misled systematics. 1. A want of distinction between final and proximate cause; between enquiries instituted in order to divine the intentions of nature, and a careful examination of the phenomena of nature as they occur in sequence. 2. The indivisibility of the body, and the universal nature of the disorder, have been too much overlooked. Fever has been considered as an affection of parts rather than of the universal system. 3. An error which appears to result from the conjunction of the two former; that shrinking and coldness of the external surface, which is merely a consequence and concomitant effect resulting from a febrile attack, has been viewed as a cause of the other symptoms which present themselves in the course of the affection.

"The remote causes of fever," says Dr. Cullen, "are certain sedative powers applied to the nervous system, which diminishing the energy of the brain, thereby produce a debility in the whole of the functions, and particularly in the action of the extreme vessels; this debility proves an indirect stimulus to the sanguiferous system, whence by the intervention of the cold stage, and spasm connected with it, the action of the heart and larger arteries is increased, and continues till it has had the effect of restoring the energy of the brain, of extending this energy to the extreme vessels, of restoring therefore their action, and thereby especially overcoming the spasm affecting them."

In the historical sketch of the progress of medical theory with which we introduced the present article, it was observed that the spasmodic theory of Hoffman engendered that of Dr. Cullen. In the hands, however, of this last systematist, the doctrine in question appears to have received mutilation rather than amendment: Dr. Cullen added another set of entangled links to the previously entangled chain. The shrinking, coldness, and general inactivity, observed at the commencement of fever fits, and which are the necessary consequences of the sudden quiescence throughout the system, induced by the peculiar action of the noxious powers producing fever, our author considers as one of nature's first steps in obtaining relief and obviating the progress of the disorder.

On this theory we may in the first place remark, that when the progress of a febrile affection is arrested by remedies applied during the first or cold stage, both the torpor of the brain and the shrinking of the surface may be removed without the intervention of the hot fit. Indeed, obviating the recurrence of this constitutes the cure of fever. The succession, then, of the hot fit is not a necessary consequence of the previous cold one, much less is it an agency contrived by nature to remedy this last. The theory is likewise "erroneous, in as far as it enters into the supposed intentions of nature."

Secondly, the action of the heart and larger arteries is not, as is justly observed by Dr. Darwin, occasioned in the mechanical manner of reaction, which the theory we are canvassing supposes. During the continuance of the cold fit, the whole circulation is lessened, or in a manner suspended, the blood is not retreating for safety to the centre, less blood passes through the lungs as well as through the vessels on the surface of the body; the fortress, and not merely the outposts, has received the attack of the enemy.' Now, when the hot fit comes on, the marks of irritation, or as Dr. Brown happily terms it, of "counterfeited vigour," by which it is characterized, are merely consequent upon the natural stimuli acting upon accumulated irritability, of irritability accumulated by the previous quiescence of the cold stage, and are not to be attributed to the blood's reacting and flowing back in order to influence and occupy the parts and cavities which it had deserted. This supposed action and reaction cannot indeed take place in that mode and to that extent which our theorists imagine. The human body is a living and not an hydraulic machine. The blood is not dammed up at one part in order to rush with violence into another. To illustrate: When even a part of the body only, as the hand, is immersed in water, or in any other way abruptly exposed to a diminished temperature for a short period, a lessened fibrous or vital action is the immediate consequence, the sensorial power or excitability accumulates in a corresponding ratio, and when the part is now again subjected to the influence of those powers which were previously operating, an irritative and disturbed, in place of regular and healthy, action succeeds; the blood, however, does not flow into the empty vessels like the waters of a river into lateral channels: not more than the same volume of blood, in cases of much weakness not so much, now circulates through parts, the excitability of which has been changed, and an accelerated, but not, properly speaking, increased motion, with febrile heat, is the consequence.

We have perhaps conceded too much to the spasmodic theory of fever, in likening the state of the surface in the cold fit to that produced in consequence of diminished temperature, for in this last the shrinking is directly produced; whereas, in fever, it is occasioned indirectly, or, as we have previously noticed, is merely one of the effects arising from the general interruption of the functions. Fever does not commence by attacking exclusively "the extreme vessels and the capillaries of the surface."

The spasmodic theory of fever then, is not only a substitution of terms for an explanation of facts, but even the phraseology which it employs in order to trace and connect the leading symptoms of the malady, appears to be deduced from defective knowledge of the laws and qualities of life. It is physically, metaphysically, and practically wrong. "Fever fits are not efforts of nature to relieve herself." Darwin.

Before proceeding further, it may be proper to notice one or two defects, as they appear to us, in the ingenious theory of the author of Zoonomia. In our remarks on nosology, the mistakes which Dr. Darwin had been led into from his untenable division of sensorial power, were hinted at. These mistakes appear to us to be evident in the learned author's attempts to form a sympathetic theory of the disorders under notice: a theory, which, in our opinion, involves the second error which we have above stated, viz. that of overlooking the indivisibility of the body, or the universal distribution of sensorial power, and regarding fever rather as an affection of parts than of the whole frame. It likewise, by consequence, embraces the erroneous doctrine of ascribing the secondary actions in fevers to the cutaneous torpor. The cold fit of simple fever, says Dr. Darwin, consists of a torpor of the cutaneous capillaries, with their mucous and perspirative glands, which is extended by direct sympathy to the heart and arteries. The torpor, however, of the heart and arteries is coexistent with, and not consequent upon, the inaction of the cutaneous vessels; the sensorial power residing in the former at the time of an attack of fever, must be affected in the same manner as the sensorial power of the latter; and the admission of association, is the introduction of an unnecessary link in the chain of cause. That distant parts sympathize with each other, in a manner which physiology has not hitherto been able to unfold, as the stomach with the surface of the body for example, is admitted; in the case of fever, however, we wish particularly to insist upon such sympathy as an explanation of symptoms being superfluous: the heart and arteries, the stomach, the surface of the body, the secretory glands, all receive a diminution or sudden interruption of their functions at the same moment of time, and from the same cause: they are simultaneous and not successive effects. Dr. Darwin seems equally unfortunate in referring the hot skin and remaining quiescence of some internal organs, as of the stomach, in the second stage of fever, to reverse sympathy. Sympathy cannot be direct in one instance, and reverse in another: "The laws of association are invariable, or they do not exist."

What then is the cause of fever? It is an abrupt suspension and consequent disruption of all the connected movements of the animal frame by which the balance of excitement is overthrown, "the laws of excitability are changed, and in consequence of which the same agents no longer produce the same effects. Fever differs from debility inasmuch as the latter is a gradual and regular exhaustion, not an abrupt interruption of the powers of life; it differs from strength, as strength consists in a powerful and equable excitement, while fever, however it may "counterfeit vigour," is never attended by the necessary constituent of vigour, regular and orderly display of power.

The primary cold, or as the Latins term it, "horror," is from the quiescence that has been induced; during this state of quiescence, a new and inordinate condition of the excitability is established, and by consequence both the external and internal stimuli excite perturbed in the place of orderly and usual actions: action without power commences; hence morbid heat is generated, diseased associations are formed, and without being in a state of actual weakness, the whole system sinks, oppressed. The plain indications of

Treatment in fever, are therefore to break the morbid associations on which this oppression is established, or obviate the symptoms by which it is continued; to diminish the cold in the cold stage, the heat in the hot stage, and not to await the sanative process of nature, either of dissolving spasm, or of correcting and expelling morbific matter. The various remedies employed for these purposes are, the external and internal use of cold and warm water; refrigerants, sudorifics, opiates, emetics, purgatives: on each of these, we shall introduce a few separate remarks; in the course of which an opportunity will be afforded, of enquiring more minutely into the pathology of the febrile state.

Of cold and tepid affusion, and ablution.—Cold water internally.—Cold air.—The medical reports of Dr. Currie, on the effects of water cold, and warm, in the treatment of fever, are introduced in the following manner:

Narrative of Dr. Wright:

"In the London Medical Journal for the year 1786, Dr. William Wright, formerly of the island of Jamaica, gave an account of the successful treatment of some cases of fever, by the ablution of the patient with cold water.

"On the 1st of August, 1777," says Dr. Wright, "I embarked in a ship bound to Liverpool, and sailed the same evening from Montego-bay. The master told me he had several sailors on the same day we took our departure, one of whom had been at sick quarters on shore, and was now but in a convalescent state. On the 23d of August, we were in the latitude of Bermudas, and had had a very heavy gale of wind for three days, when the above-mentioned man relapsed, and had a fever with symptoms of the greatest malignity. I attended this person often, but could not prevail on him to be removed from a dark and confined situation to a more airy and convenient part of the ship; and as he refused medicine and even food, he died on the eighth day of his illness.

"By my attention to the sick man, I caught the contagion, and began to be indisposed on the 5th of September; and the following is a narrative of my case, extracted from notes daily marked down: I had been many years in Jamaica, but except being somewhat relaxed by the climate and fatigue of business, I ailed nothing when I embarked. This circumstance, however, might perhaps dispose me more readily to receive the infection.

"Sept. 5th, 6th, 7th: Small rigours now and then; a preternatural heat of the skin; a dull pain in the forehead; the pulse small and quick; a loss of appetite, but no sickness at the stomach; the tongue white and slimy; little or no thirst; the belly regular; the urine pale and rather scanty; in the night restless with starting and delirium.

"Sept. 8th. Every symptom aggravated; with pains in the loins and lower limbs, and stiffness in the thighs and hams.

"I took a gentle vomit on the second day of this illness, and next morning a decoction of tamarinds; at bed-time an opiate joined with antimonial wine; but this did not procure sleep or open the pores of the skin. No inflammatory symptoms being present, a drachm of Peruvian bark was taken every hour for six hours successively, and now and then a glass of port-wine, but with no apparent benefit. When upon deck my pains were greatly mitigated, and the colder the air the better. This circumstance, and the failure of every means I had tried, encouraged me to put in practice on myself, what I had often wished to try on others, in fevers similar to my own.

"Sept. 9th. Having given the necessary directions, about three o'clock in the afternoon I slipt off all my clothes, and threw a sea-cloak loosely about me till I got upon deck, when the cloak also was laid aside: three buckets of salt water were then thrown at once upon me; the shock was great, but I felt immediate relief. The head-ache and other pains instantly abated, and a fine glow and diaphoresis succeeded; towards evening, however, the same febrile symptoms threatened a return, and I had again recourse to the same method as before, with the same good effect. I now took food with an appetite, and for the first time had a sound night's rest.

"Sept. 10. No fever, but a little uneasiness on the hams and thighs; used the cold bath twice.

"Sept. 11. Every symptom vanished; but to prevent a relapse I used the cold bath twice. Mr. Thomas Kirk, a young gentleman, passenger in the same ship, fell sick of a fever on the 9th day of August; his symptoms were nearly similar to mine, and having taken some medicines without experiencing relief, he was desirous of trying the cold bath; with my approbation he did on the 11th and 12th of September, and by this method was happily restored to health. He lives at this time (Jan. 1786) near Liverpool."

We have thus presented our readers with this important narration of Dr. Wright, both as it furnishes a history of fever, as it details the mode in which the cold affusions should be employed, and as it was confessedly the means of introducing this most valuable remedy into general practice. We shall now add from Dr. Currie the more particular rules which ought to govern the use of the affusion or aspersion of cold water in fevers, and then make one or two observations on the nature of its operation.

"The safest and most advantageous time," says Dr. Currie, "for using the cold water is, when the exacerbation is at its height, or immediately after its declination has begun; and this has led me almost always to direct it to be employed from six to nine in the evening; but it may be safely used at any time of the day, *when there is no sense of chilliness present, when the heat of the surface is steadily above what is natural, and when there is no general or profuse perspiration.*—These particulars are of the utmost importance: for, 1st. If the affusion be used during the cold stage, the respiration is nearly suspended; the pulse becomes fluttering, feeble, and of incalculable frequency; the surface and the extremities become doubly cold and shrivelled, and the patient seems to struggle with the pangs of instant dissolution. I have no doubt, from what I have observed, that in such circumstances the repeated affusions of a few buckets of cold water would extinguish life. This remedy should therefore never be used when any considerable sense of chilliness is present, even though the thermometer applied to the trunk of the body, should indicate a degree of heat greater than usual.

"2nd. Neither ought it to be used, when the heat measured by the thermometer is less than, or even only equal to, the natural heat, though the patient should feel no degree of chilliness. This is sometimes the case towards the last stages of fever, when the powers of life are too weak to sustain so powerful a stimulus.

"3d. It is also necessary to abstain from the use of this remedy under profuse sensible perspiration, and this caution is more important in proportion to the continuance of this perspiration."

"Under these restrictions," our author adds, "the cold affusion may be used at any period of fever; but its effects are more salutary in proportion as it is used early. When employed in the advanced stages of fever, where the heat is reduced and the debility great, some cordial should be given immediately after, and the best is warm wine."

Observations. Cold water, as a remedy for fever, may be conceived to operate upon a twofold principle. In the earlier stages, and before the vital power is too much harassed and oppressed to endure a violent shock, the copious and sudden affusion of cold water all over the naked body, appears to effect its beneficial purposes in part by the abruptness of its agency; it in a manner severs the chain of diseased associations, and restores the healthy and orderly movements of the frame. This operation is not, as has been suggested, mechanical: it is in some measure similar to that produced by the operation of an emetic, to which it is in every respect greatly preferable, or to sudden mental agitation. In the language of the schools, it cuts short fever.

When, however, the diseased associations are more firmly established, and the vital power greatly oppressed by the disorder's continuance, although the surface of the body retains its morbid heat, the water is to be applied, not in the way of sudden affusion, but by washing with a spunge, and this under the restrictions enjoined by Dr. Currie, or we may safely say, while it is found genial to the patient's feelings, ought to be resorted to in every case of simple fever. The action of the water at this time is somewhat different from that in the previous period, or under different circumstances of the disorder. It proves a direct stimulus. But how, it has been urged, can the negative of a power prove stimulative? "Darkness might as well be called a stimulus to the eye, or hunger a stimulus to the stomach, as cold to our sense which perceives heat." Darwin. To this it has been replied by Dr. Currie, and before him by Dr. Beddoes, that the objection is founded upon a disregard of the sentient principle: "Cold," says the latter author, "may very often be so applied as, by removing the very disagreeable sense of heat, that attends some diseases, to produce an effect equivalent to stimulation. It is, I believe, exactly in this way, that bathing the body with cold water proves serviceable in low fevers."

From the urgency, however, of the debility, or from the prejudices of the patient or his friends, in some periods of fever, even the application of cold water in the way of ablution may be regarded as too severe. In this case tepid ablution has been made to supply its place, and often with propriety and success; it is, however, particularly deserving of remark, that unless this last be used with precaution, the object of the practitioner in its choice is defeated, as the evaporation from the surface is more copious from the tepid affusion; and this is one of the most powerful, indeed, strictly speaking, the only means of abstracting heat. The term tepid is applied by Dr. Currie to water, from 87° to 97° of Fahrenheit; from 87° to 75° the water is denominated cool. Cold water may be given internally, and with the utmost freedom, in the hot stage of the febrile paroxysm. Its use, however, requires to be carefully regulated by the same restrictions as in the external application; it must never be given unless the heat of the surface be steadily above the natural standard. Draughts of cold water have been known, when properly administered, to procure a sudden solution of the disease.

Cold air. The extraordinary melioration in the modern practice of medicine, as it relates to the treatment of fever and febrile diseases, is not confined to the copious use of affusion and ablution. The terrors of our predecessors, in relation likewise to cold air, are fast departing; and the importance of its free admission in the apartments of the febrile sufferer especially, comes to be generally acknowledged and applied. It has been stated by a physician, above all praise for fidelity of observation and justness of remark, that the corrupted air of sick rooms, from neglect of ventilation, has been much more fatal even among the higher classes of society, than the virulence of the disease itself: "Vereor ne quidam ægroti non tam morbo suo perierint, quam halitibus putribus, quos discuti vetuit præpostera amicorum cura." Heberden.

The utility of cold air in fever is referable to two principles: 1st. That of immediately lowering the heat of the surface, and thus taking off the oppression occasioned by such heat: and 2ndly, from affording a larger quantity of oxygen at each inspiration. The first of these principles is sufficiently evident, and does not require any further illustration: if cold ablution prove beneficial chiefly by virtue of diminishing the temperature of the body, it necessarily follows that coldness in the circumambient atmosphere must be attended with precisely similar effects: but on the purity, as connected with diminished temperature of the atmosphere, it may not be improper to embrace the present opportunity of offering one or two remarks. A given bulk of air at an inferior temperature, contains more of the oxygenous principle than the same quantity at a superior degree of heat; hence the greater refreshment which is experienced from the inhalation of a cold and dense, over that of a warm and rarefied atmosphere; hence, in part, the more vigorous digestion and keen appetite of a healthy individual during the winter, than the summer months; and finally, by the relief a febrile patient experiences from the inspiration of such air, it is rendered evident, both that the heat of fever originates, and is kept up, independently of those organs which modern chemistry and physiology have supposed to be the sole organs for the supply of heat to the living system. From this fact Dr. Reid infers, and we think with justice, that the constant equality of animal temperature in a condition of health, has more dependance upon living actions in general than upon the chemical evolution of caloric in the lungs, according to the ingenious theory first suggested by Dr. Crawford, but since materially modified. See PHYSIOLOGY.

But the frigorific virtue of a more oxygenous atmosphere, when received into the lungs of a febrile invalid, is a further proof, that however violent the reaction, as it has been erroneously called, such reaction is, in every case of genuine fever, far from being an evidence of actual increase of power. Whatever theory we adopt respecting the precise mode in which pure air influences the animal economy, an uniformity of opinion must prevail, that it is, in the strictest sense of the word, an exciting agent. Now as far as it operates beneficially in fever, it reduces the inordinate heat; that power then which actually and properly excites, by this very agency moderates the turbulent action, and by consequence reduces the prevailing morbid heat. The admission of cold air requires likewise to be restricted to the hot stage, and to be limited by the patient's feelings; a current of cold air passing rapidly over the body while in a state of perspiration, may be productive of fatal consequences.

Of refrigerants in fever. Besides, however, the employment of cold water, and the free admission of a cool and pure atmosphere, other agents have been had recourse to, and with considerable effect, in order to abate the inordinate heat of fever. From possessing the faculty of cooling the system, certain medicines have been distinguished by the term refrigerants: refrigerants are principally chosen from the vegetable acids, and the different neutral salts; and so evident is their power in reducing animal temperature, that they have properly been made to constitute a considerable part of regimen in fever. Indeed nitre, and other neutral salts, with the vegetable acids, have been received into some systems of classification, under the distinct head of febrifuge medicines. The modus operandi of refrigerants has not perhaps hitherto received explanation; the substances of which they are composed are for the most part those which contain oxygen in a concentrated, and, at the same time, loose state of combination; from this circumstance, their action has been ingeniously but not perhaps satisfactorily accounted for. "It has been sufficiently established," says a modern writer, "that the consumption of oxygen in the lungs is materially influenced by the nature of the ingesta received into the stomach; that it is increased by animal food and spirituous liquors, and, in general, by whatever substances contain a comparatively small quantity of oxygen in their composition. But the superior temperature of animals is derived from the consumption of oxygen gas by respiration; an increase of that consumption must necessarily, therefore, occasion a greater evolution of caloric in the system, and of course an increase of temperature, while a diminution in the consumption of oxygen must have an opposite effect. If, therefore, when the temperature of the body is morbidly increased, substances be introduced into the stomach, containing a large proportion of oxygen, especially in a state of loose combination, and capable of being assimilated by the digestive powers, the nutritious matter received into the blood must contain a larger proportion of oxygen than usual; less of that principle will be consumed in the lungs, by which means less caloric being evolved, the temperature of the body must be reduced; and this operating as a reduction of stimulus, will diminish the number and force of the contractions of the heart." Murray's Materia Medica.

This reasoning is perhaps more specious than just. In the first place, the remarks which we have above introduced on the actual diminution of febrile heat from inhaling an oxygenous atmosphere, seem to oppose the theory of refrigeration, from " less of the oxygenous principle being consumed in the lungs." Secondly, it may be noticed that the effects of these medicines are too speedy and direct to admit of the supposition of this intermediate kind of agency; and thirdly, although the refrigerantia are for the most part, they are not universally, substances which contain this suberabundance of the oxygenous principle. The saline draught, for example, appears to moderate febrile heat, principally by reason of the carbonic acid gas that it contains.

Chemical reasoning has recently been extensively applied to the developement of the mode in general in which the functions of the stomach and lungs are connected, and as this enquiry is closely related both to the theory of febrile heat, and the dietetical as well as the medicinal management of the febrile invalid, it may not be improper to detain the reader by one or two further reflections on this very interesting point of discussion. It is an axiom of Hippocrates, that animal food should not be given in fever; an axiom which was no doubt founded upon observation of its general irritating and disordering tendency. Modern physiology, however, has not rested content with a knowledge of the fact, but has endeavoured to divine its immediate cause. That digestion of the food is, cæteris paribus, in proportion to the oxygenation of the blood; or to avoid an expression involving theory, to the purity of air and freedom of inspiration, which an individual enjoys, is without question; and it is further evident from daily observation, that the facility of assimilating animal food, in particular, is increased by air, exercise, and whatever promotes an uninterrupted circulation through the pulmonary organs. Hence it is said, we are furnished with an explanation why animal diet is uncongenial to the patient in fever. The pulmonary circulation is impeded by febrile oppression, less oxygen is received from the atmosphere, and the power of assimilating materials which contain the hydrogenous and azotic principles in abundance is consequently weakened, or, as we have heard it expressed still more chemically, less fuel or combustible matter is required, on account of there being less power of consuming such fuel, or of maintaining combustion.

Perhaps the peculiarity or distinct nature of living action, has not been sufficiently attended to by modern physiologists of the chemical school. That hypothesis, the outline of which we have just delineated, appears at first sight perspicuous and unobjectionable, but when pursued more in detail, facts present themselves which are in some measure at variance with its fundamental principles.

Animal food may, perhaps, prove less congenial to the patient in fever, than under circumstances of debility without febrile disturbance, on account of the direct irritation it communicates to the fibre, independantly of its chemical properties; the difference between animal and vegetable diet in this particular, is abundantly obvious. But it may further be urged, that several materials taken into the stomach during the burning heat of fever, appear to be productive of nearly similar effects, in their immediate operation, with a diet of animal food; of this we have an instance in opium. Opium, which when duly administered is congenial and salutary, when given while the skin is dry, and there is no disposition to perspiration, proves irritating and hurtful; it still further impedes the weakened digestive organs, augments the tendency to costiveness, and increases febrile heat. These properties it surely does not possess by virtue of the quantity of hydrogen or azote that it contains.

Of Sudorifics.

We now proceed to consider the agency of sudorifics as febrifuge remedies. Moisture on the surface of the body may be procured by medicines which appear to have a direct power over the cutaneous vessels, or by those whose action seems to be directed primarily to the stomach. These last are principally of the saline class, which are by far the most suitable in the febrile state.

The physiology of perspiration, and the principles by which it operates as a cooling process, are, notwithstanding the recent discoveries in chemistry, and their application to this interesting subject, still involved in much obscurity.

The ancients imagined sweat to be not merely an excrementitious product, but the vehicle of conveying that morbific matter out of the body which had been the occasion of disease. This opinion does not, in the present state of science, require to be confuted. The questions of most interest, respecting the phenomena and causes of perspiration, are, in what relation does it stand to the respiratory function; and is that moisture on the surface of the skin which closes a febrile paroxysm, to be regarded as a cause or consequence of the disorder's declination?

" That an animal," says Dr. Currie, " possesses to a certain extent the faculty of rendering sensible heat latent, or, to speak more philosophically, of reducing caloric from a free to a combined state, in cases in which the stimulus of heat might otherwise overpower the living energy, there is reason to believe, from a variety of experiments and observations; and that this is in part performed by perspiration from the surface can scarcely admit of a doubt. The process of perspiration, which is continually going on from the surface of the body, is in this point of view the converse of respiration; as in respiration a gas is constantly converted into a solid or fluid, and thus heat evolved, so in perspiration a fluid is constantly converted into a vapour, and thus heat is absorbed. A vessel filled with water and exposed to the atmosphere, cannot be raised above 220° of Fahrenheit by any quantity of fuel, because, heat is applied from below, evaporation carries it off from the surface; in like manner we may suppose the heat of the living body to be kept uniform, by the evaporation from its surface increasing or diminishing, according to the quantity of heat extricated from the system, or received from the surrounding medium."

These speculations are beautiful and highly ingenious. It however admits of question, whether Dr. Currie, in applying them to the subject of febrile heat, may not have given too much weight to the analogy of absorption of caloric in inanimate matter, as explanatory of the cooling process in the living body; and whether sensible perspiration, produced by medicine or otherwise, may not be consequent upon, rather than prior to, the diminution of febrile heat? If, for example, a large quantity of water be swallowed in the height of a febrile paroxysm, and be directly succeeded by general diaphoresis, or sweat, with relief from the burning sensations of fever, although it be natural to attribute such relief to the sweat that is produced, this last may be subsequent to that altered condition of the fibre by which the evolution of caloric is diminished. Such an opinion has been ingeniously argued by Dr. Reid; and if the following observations of Dr. Darwin are just, they appear to place the matter beyond dispute. " The perspirable matter," says this last author, " is secreted in as great quantity during the hot fit of fever, as towards the end of it, when the sweat is seen upon the skin. But during the hot fit, the cutaneous absorbents act also with increased energy, and the exhalation is likewise increased by the greater heat of the skin; and hence it does not appear in drops upon the surface; but is in part reabsorbed and in part dissipated in the atmosphere. But as the mouths of the cutaneous absorbents are exposed to the cool air or bed-clothes; while those of the capillary glands, which secrete the perspirable matter, are exposed to the warmth of the circulating blood; the former, as soon as the fever fit begins to decline, lose their increased action first; and hence the absorption of sweat is diminished, whilst the increased secretion of it continues for some hours afterwards, which occasions it to stand in drops upon the skin. As the skin becomes cooler, the evaporation of the perspirable matter becomes less as well as the absorption of it. And hence the dissipation of aqueous fluids from the body, and consequent thirst, are perhaps greater during the hot fit than during the subsequent sweat. For the sweats do not occur, according to Dr. Alexander's experiments, till the skin is cooled from 112 to 108 degrees of heat; that is, till the paroxysm begins to decline. From this it appears that the sweats are not critical to the hot fit, any more than the hot fit can be called critical to the cold one, but simply that they are the natural consequences of the decline of the hot fit. And from hence," continues our author, " it may be concluded, that a fever fit is not an effort of nature to restore health, but a necessary consequence of the previous torpor; and that the causes of fever would be less detrimental, if the fever itself could be prevented from existing, as appears in the cool treatment of the small pox."

Of Purgatives and Emetics.

Nothing, perhaps, is of greater moment in almost every stage and every kind of fever, than to preserve the whole of the alimentary canal free from accumulations of colluvies, &c. From a deficient attention to this principle, the medical practitioner is in many instances foiled in the treatment of this, and indeed in a variety of other diseases. Viscidities and impurities in the stomach and bowels, are often both effect and cause of the persistance of the febrile state; for as the powers of assimilation are weakened by the induction of fever, so the consequent accumulations of foreign matter in the alimentary and intestinal canal, themselves prove direct sources of irritation and disorder. In the primary stages of fever, an emetic has been known abruptly to arrest its progress, and the same purpose is sometimes accomplished, especially in ephemeral affections of the febrile kind, by the employment of a brisk purgative. In the more advanced periods however of the disorder, the object of the physician ought to be rather that of keeping the bowels gently open, and this is best effected by saline in place of drastic purgatives; the former of which principally operate by exciting the exhalants on the internal surface of the intestines to pour out their contents, the latter by stimulating in a forcible manner the intestinal fibre.

It is a fact worthy particular notice in the treatment of fevers especially, that where due attention is given to ensure regular evacuations from the bowels, those stimuli, the copious use of which is often necessary to support the sinking powers in the last stages of the disease, are more freely admissible and abundantly more efficacious: this is indeed an important principle in the treatment of diseases generally; and it is perhaps chiefly by virtue of preserving the excitability in an orderly and due condition for the agency of other stimuli, that purgatives, like sudorifics, form so useful, and indeed the former, almost an indispensable, part of the remedial process in the greater number of aliments. In intermittent fevers it is generally necessary to evacuate the bowels by more stimulant cathartics, more especially when the cure of these fevers is conducted by the Peruvian bark.

Having thus discussed the nature, causes, and treatment of fever, it may be proper to present the reader with a recapitulatory view of the remedies which are required in the different forms of this affection: as a preliminary, however, to such recapitulation, we shall make one or two remarks on the more unfavourable symptoms with which fever is sometimes attended, and on the periods in which the disorder displays a greater or less disposition to terminate.

The unfavourable signs are, in the first place, an abrupt alteration of type. If during fever, indicating in its primary stages no particular severity of disease, a rapid change take place in the feelings and expressions of the invalid; if upon the more ordinary symptoms, suddenly and unexpectedly supervene delirium, prostration of strength, an observable change in the countenance, accompanied by irregular and partial alternations of heat and cold, without the intervention of the perspiring state, the patient's life is in considerable danger. The above changes are often indeed preludes to a speedy death.

Weakness, quickness, and irregularity of pulse, delirium, tendency to fainting when in an erect posture, prostration of strength, partial and irregular sweats, difficult respiration and deglutition, starting of the tendons, unusual fœtor in the excretions, great foulness of the tongue and fauces, are all evidences of a fatal tendency in the complaint; in general likewise it may be observed, that in cases where marks of great nervous irritation attend the onset of a fever, even though the disorder may not assume what has erroneously been termed the putrid type, much danger is to be apprehended. Indeed, the management of fever is not seldom rendered more difficult, and the indications of treatment less decided, from the absence of such type. Genuine nervous fevers are often the most obstinate and malignant.

In fevers of this kind, indeed, the heat is often so partial and irregular as not to admit of the cold affusion. Dr. Currie in his Medical Reports, describes a fever in which this remedy was tried without success. This fever, says Dr. Currie, does not appear to originate in contagion, or to be propagated by contagion.

Calculations respecting critical days have been in some measure forced and systematic. It is worthy however of remark, that continued fevers as well as intermittent, in the successive stages of their course, are disposed to assume progressively the quotidian, tertian, and quartan aspect.

Thus, if the fever has lasted more than a week, the ninth and eleventh days from its first attack are those on which we may anticipate its declination; after the second week the seventeenth and twentieth are the more usual days of termination. These, however, are by no means unexceptionable rules.

RECAPITULATION OF THE TREATMENT OF FEVER.

Treatment of continued fever during the first three or four days. Cold affusion. Water to be impregnated with salt, its application to be confined to the hot stages of the paroxysm. Large draughts of cold water taken under the same limitation. Cold and pure air. Emetics. Purgatives. Antimonial and saline sudorifics.

After the fifth or sixth day. Cold and tepid ablution. Water employed to be impregnated with salt or mixed with vinegar. In the urgency of debility, coldness, or delirium, pediluvium or the warm bath. Bowels to be kept gently but constantly open, by saline or mild purgatives and subacid drinks. While the skin is preserved moist by diaphoretics, give opiates and wine; these last are almost invariably improper when the skin is dry and hot, and the bowels costive. For head-ache and other nervous affections, blisters, æther, camphor. In the last stages, when critical sweats break out, and the powers of life appear to be shrinking from the contest, repeated glasses of port wine with tincture of opium in large quantities. During the whole course of the disease, the apartment to be diligently preserved cool, clean, constantly ventilated, and free from all individuals but those who are necessary attendants on the sick.

Treatment of intermittent fever. Cold affusion immediately upon the full accession of the hot fit. Warm bath, warm spiced wine, during the cold stage of the paroxysm. Tincture of opium, either previous to the accession of the cold, or towards the decline of the hot fit. Emetics, immediately preceding the accession of the paroxysm. Calomel purges before the administration of tonics; arsenic, zinc, Peruvian bark, quassia, and if any enlargement of one of the viscera (ague cake) appear, steel. Hope: upon the excitation of hope the power of charms altogether depends; these sometimes succeed in ague, when other remedies are counteracted by the violence of the complaint.

Although we have judged it expedient to enumerate the different medicines which in the event of fever's protraction may be requisite, it is proper to observe that the progress of the complaint may for the most part be abruptly arrested, and the necessity of other means of cure consequently superseded, by an early and judicious employment of the cold affusion. If the application of the water in the mode described in the narrative of Dr. Wright be objected to, a shower bath may be employed, or, what is an excellent and convenient substitute for the latter, a common gardener's watering-pot; the patient is to be taken out of his bed, if convenient, conducted or carried into an adjoining apartment, and the water poured from this instrument as hastily as it will admit of over his naked body; the skin is then to be quickly and effectually dried with towels, and the invalid reconducted to his bed; this course is to be repeated with the full recurrence of the hot paroxysm, even should this be on the same day, and continued, if requisite, on the following days, until the disorder's decline; or, in the pointed language of a modern writer, until "the fever be washed away." (Reid's Medical Reports, Monthly Magazine.)

Fever Houses, &c.

The rapid and extended diffusion of fever through families and districts might be deemed sufficient evidence in favour of matter engendered by febrile action, having the power to produce a similar disorder in another individual. The fact, however, appears to have been placed beyond doubt by the unfortunate result of several experiments made with sceptical temerity in order to prove the negative of this assumption.

While the writer of the present article was pursuing his studies in the Edinburgh university, several anti-contagionists, as these gentlemen were denominated, freely exposed themselves within what they regarded the imaginary sphere of contagion, in the wards of the infirmary of that city; many in consequence became infected with fever, and in some instances the disorder had a fatal termination. In these instances the production of the disease could not be referred to want of cleanliness, or to any peculiar condition of the atmosphere; for the fever did not extend to those gentlemen attending the hospital, who were fortunate enough to remain satisfied with the previous evidence in favour of contagion.

But with a knowledge of the evil, we have at length acquired a knowledge of its antidote; and it has been demonstrated by experiments upon a most extensive scale, that, whether the matter producing fever be introduced into the system by the lungs, the surface of the body, or the stomach, its power to infect extends but an exceedingly small distance—three feet at furthest—from the patient in whom it is generated, "when he is confined where the air has free entrance and egress." This fact, it has been well observed, "cannot be corroborated by too great a variety of testimony, nor repeated too often, until it shall be familiar not only to the most unlearned of the profession, but well known to the community at large." (Dr. Bateman.)

Its application with that of another fact immediately to be mentioned, has already gone a considerable way towards the actual extermination of febrile contagion.

This second fact is, that although infectious matter be rendered almost immediately inert by exposure to the air, it is capable of being rendered concentrated, and even transported to an unlimited distance, when made to come in contact with any material, even "a rag or a bit of lint," if such material be excluded from the air. From these, one should expect unquestionable premises, separate receptacles, apartments, and houses, have been exclusively devoted to the admission of the sick in fever, and, as we have just observed, with the most evident and extended benefit, particularly to the inferior classes of the community.

The example of fever institutions was set to the metropolis by the very active and laudable exertions of provincial physicians. In Chester, Manchester, Liverpool, Dublin, Cork, and other large towns in the British isles, the plan of thus separating the infectious fevers from other diseases, had already been adopted, and at length an establishment of this kind was founded in Gray's-inn-lane, in London, and with the happiest effects. Among the internal regulations of these houses, the following are the most important;—they have been adopted in the fever wards of common hospitals, and apply in a general manner to private practice.

Every patient when admitted into the house, is to change his infectious for clean linen; the face and hands are to be washed clean with warm water, and the lower extremities fomented. "The effect which this salutary change has upon the patient before any medicine is given, is often more beneficial than those which all the febrifuge drugs in the world could bestow." All discharges are to be speedily removed. The floors of the sick room are to be washed twice a week, and near the beds every day. The clothes which the patient brings with him are to be carefully purified by washing the linen, and exposure for a length of time of the other habiliments to pure air.

Blankets and other bed-clothes are to be exposed to the open and fresh air before they are used by another patient. Several windows of the apartment to be constantly opened in the day, unless the weather is very cold and wet; and some of them should not be shut in the night, if the patients are numerous, and the weather moderate.

By a due enforcement of these regulations, the necessity in general may be obviated of employing the acid fumigations recommended by Morveau, Carmichael Smith, and others, which have been ingeniously, and we think justly, imagined to operate upon the same principles with atmospheric or pure air, viz. by oxidating, and thus destroying the virulence of the contagious effluvia.

By cleanliness then, and procuring a free circulation of air, by guarding against the lodgment of contagious matter, and by keeping as much as possible from actual contact with the sick in fever, every cause is obviated from which infection can be communicated. The individual who resides in the house adjoining to a fever institution is equally out of the sphere of contagious influence with one at fifty miles distance; nay, in the contiguous apartment, and even in the sick room itself, the immunity is precisely the same: such are the preventive as well as the sanative effects of cleanliness and ventilation, which, whether in sickness or in health, cannot be too highly appreciated, or too extensively adopted.

ORDER II.—*Phlegmasiæ*, Inflammations.

When any part of the body has an unusual heat and redness, with pain and swelling, it is said to be inflamed. To constitute this state of a part, an inordinate action and dilatation of vessels have generally been esteemed sufficient. Such opinion, however, has been questioned by the author of Zoonomia. "Inflammation," says Dr. Darwin, "is uniformly attended with the production or secretion of new fibres, constituting new vessels; this, therefore, may be esteemed its essential character, or the criterion of its existence. The extension of the old vessels seems rather a consequence than a cause of the germination or pullulation of these new ones; for the old vessels may be enlarged and excited with unusual energy, without any production of new ones, as in the blush of shame or of anger." On the contrary, however, we are disposed to regard the formation of new vessels, which does not perhaps take place in every case even of genuine inflammation, to be subsequent to, and not the occasion of, capillary dilatation. The case which Dr. Darwin puts in opposition to this theory is not in point. It is permanent and forcible, not transient and slight, extension of blood vessels, which constitutes the inflamed state. The eye may be exposed to a vivid light, its vessels consequently act with more than ordinary excitement, and this to a certain extent without actual inflammation; but if such excitation be extended beyond a certain point, the small vessels of the organ shall be deprived of their proper resistance, and thus shall not merely transmit a more than due quantity of blood, but such blood shall in a manner become congested in their vessels, and shall cause pain, unusual redness, heat, and tumour. This induced weakness of the capillaries, ought then, perhaps, according to the opinion of some modern physiologists, to be regarded as the proximate cause of inflammation; the too great or too little excitement on which it may have depended the remote cause; and the increased action of the larger vessels of the part, the proximate effect. The augmented action, if considerable, is accompanied by an irritation of the whole system; such irritation constitutes the "sensitive irritated fever" of Dr. Darwin, which is distinguished from simple, or what we have considered genuine fever, by its being a sequente of local affection.

Sthenic and asthenic inflammation. The disturbance of the system does not correspond more with the magnitude of the local disorder, than with the constitutional character of the individual affected. Of two persons that are the subjects of inflammation, as of the mucous membrane of the nostrils, constituting inflammatory catarrh, or a cold; of the pulmonary vessels, occasioning inflammation of the lungs; or of the joints, forming rheumatism; one shall previously have possessed much constitutional vigour, the other shall have been languid and feeble—the former will have a sthenic, the latter an asthenic disease. This distinction in practice will be found of immeasurable importance. It was first distinctly pointed out by Dr. Brown. We believe, however, that this author was mistaken in the mode in which the inflammation of a part, and the disorder of the system, are connected; for the purpose of confirming his favourite tenet of sthenic and asthenic disorder, he laboured to prove that the systematic in many cases of inflammation actually preceded the local disease —this is not the case. Even in the most violent forms of pneumonia, the disorder of the lungs precedes that of the system; and indeed sthenic disorder, independantly of local irritation, is in some measure a contradiction in terms. High excitement, to whatever extent it may be carried, while there is no irregularity or want of balance in any of the corporeal or mental functions, and no affection of a part, cannot be properly regarded as a disease, however it may predispose to the diseased state.

Termination of inflammation. Inflammation is said to be resolved when the natural state and action of parts are renewed without disorganization. If, however, the inflammation has existed for any time, or has been violent, an unnatural secretion takes place from the vessels inflamed, which is called pus; this when collected or confined, constitutes abscess, and when the inflammation ends in this manner, it is said to terminate by suppuration. In cases of much weakness, constitutional or induced, the vascular action in the part shall cease altogether, its excitability be irrecoverably exhausted, and what in scholastic language is termed gangrene be the consequence, which extending, shall form sphacelus, or mortification. Resolution, suppuration, gangrene, are therefore the usual modes in which inflammation terminates. There are others, however, which are peculiar to certain parts; thus, an inflammation of the lungs often ends fatally by a copious effusion of a watery matter into the cellular texture of these organs; thus, an inflammation of a gland shall end in schirrus, or hardness of the parts, depending perhaps upon the deposition of matter which remains unabsorbed.

Species of inflammation. This disorder is systematically divided into two leading species—phlegmonous and erythematic. The first is defined by Dr. Cullen, "an inflammation of a bright-red colour, with a circumscribed pointed tumour, and tending towards suppuration." The erythema has a less vivid colour, with scarcely any tumour, spreading irregularly, burning rather than throbbing pain, and terminating in vesicles.

These species are principally established by the difference of part upon which the inflammation may happen to fall. Thus if the disorder be seated superficially, or in any internal part where there is an uninterrupted expansive or cellular texture, it will be erythematic or spreading; if it be more deeply lodged among muscular substance, it will be for the most part phlegmonic.

Indications of the disorder's decline. It scarcely requires to be observed, that a cessation of pain, a reduction of tumor, a loss of redness and heat, a diminution of the systematic disturbance, are all evidences that the inflammation is about to terminate. If, however, it be suffered to run on into the stage of suppuration, the indications of this state are, the pulse becoming fuller and softer, the patient being attacked with shiverings, and a pulsatory feel in the affected part. Again, the tendency to gangrene is denoted by the tumour losing of its redness, and assuming a darker hue; by the sudden cessation of pain; sometimes by blisters arising near or upon the tumour; and, lastly, if the local disorder have been considerable, by a rapid declension of the pulse, and powers of life.

Treatment. The indications of cure are to be deduced from the sthenic or asthenic disposition of the disease, and from the peculiar nature of the part or organ injured.

Before the time of Dr. Brown, action, at least inflammatory action, was too indiscriminately viewed as an evidence of power; the inference from this highly erroneous doctrine was, that inflammation almost invariably required for its cure a debilitating and evacuating plan of treatment. Nothing can be more inconsistent with the laws of the animal economy.

"It had been," says the author of the Elementa Medicinæ, "a prevailing opinion that the fits of the gout could not be constituted by debility, because inflammation accompanies them. This question he subjected to the test of experiment. He invited some friends to dinner; and by taking stimulants in their presence, recovered the most perfect use of that foot with which, before dinner, he could not touch the floor for pain. By this he saw, that not only the gout itself, but the inflammation accompanying it, was asthenic, that is, depending upon debility. Such he found likewise to be the nature of the inflammations in the gangrenous sore throat, in chronic rheumatism, &c. &c." The application of this principle in the practice of medicine has proved of incalculable importance. In conducting the cure, then, of inflammation, the physician is to be guided not so much by the extent and degree of the local injury, as by the nature of what Brown calls the prevailing diathesis; if inflammation be attended by a full, hard, and vigorous pulse, with other expressions of power, a debilitating plan of treatment is to be adopted; blood is to be drawn from the arm, saline purgatives are to be administered; cold, under the limitations immediately to be mentioned, is to be applied, and the exciting powers as much as possible withdrawn. If, on the contrary, an equal degree of local affection shall be accompanied with feeble, although quick, pulse, and the remaining symptoms of debility, an opposite plan, under certain regulations and exceptions, is to be pursued; stimulants are to be thrown in, and the inflammation cured by impelling and supporting the torpid and feeble powers of the frame. But from the peculiar nature of the part or organ affected, the mode of treatment in the same degree and kind of inflammation will likewise be materially modified. Thus an asthenic affection of the liver requires different stimuli from an asthenic affection of the stomach.

Again, although in inflammation, as in fever, we generally recommend the cool treatment, and consequent free admission of air, it is to be recollected that this principle is objectionable in some kinds of inflammations, as of the lungs. For example, in small-pox and in measles, we shall have the same degree of pyrexia, or fever, present; and cold air would be equally indicated in either, were we to infer the proper method of treatment alone from the inflammatory excitement; but in measles the lungs are often the principal seat of the local affection, an oxygenous or pure atmosphere would prove too stimulating to these organs; and thus if we pursued general doctrines without particular exceptions, or overlooked "the peculiar nature of the part or organ injured," the object of our plans would be frustrated and defeated.

As it relates to this important principle in medicinal agency, the system of Dr. Brown is exceedingly deficient. The peculiar susceptibility of the separate organs our author overlooked in the rapid and general survey which he took of the animal economy.

Genus I. *Ophthalmia*, inflammation of the eyes. See SURGERY.

Genus II. *Phrenitis*, inflammation of the brain. This, as a sthenic affection, independently of proper maniacal disorder, or febrile affection, is an extremely rare disease.

Symptoms. Redness of the face and eyes, impatience of light and sound, watchfulness, and furious delirium.

Methodus medendi. Copious evacuations. "Foment the head with cold water for hours together." Blisters. Blood to be drawn from the temporal artery.

N. B. The delirium of fever, which has been supposed to indicate an inflammation of the brain, is for the most part of an asthenic nature, and requires stimuli.

Genus III. *Cynanche*, quinsy.

Species 1st. Cynanche tonsillaris, common inflammatory sore throat.

M. M. Acid gargles. Saline purgatives. Blisters. Antimonial diaphoretics.

Species 2d. Cynanche maligna. An accidental, but very common, symptom of scarlet fever. See SCARLATINA.

Species 3d. Cynanche trachealis, croup. See INFANCY.

Species 4th. Cynanche pharyngæa, a mere extension into the pharynx of the cynanche tonsillaris.

Sp. 5th. Cynanche parotidæa. The mumps is an affection of the parotid and maxillary glands, which appears in the form of a swelling under the jaws: it is more common in some than in other counties of England. It sometimes appears as an epidemic. The mumps is in itself a slight disease; but after its declension, which is in general about the fourth day, the testes in men, and breasts in women, are very apt to be affected with swelling, in consequence of some peculiar sympathy of these parts with the throat.

M. M. If delirium supervene upon the retrocession of the swellings, blisters. "Foment the head with warm water." Darwin.

Genus IV. *Pneumonia*, inflammation of the lungs.

Genus V. *Carditis*, inflammation of the heart or pericardium.

Genus VI. *Peritonitis*, inflammation of the peritoneum.

The disorder which is usually termed inflammation of the lungs varies in some measure its seat. Thus the diseased action shall be directed towards that part of the pleura which is called the pericardium, and then it may be called carditis; or it may pass down the diaphragm, or the peritoneum, and form the peritonitis of Cullen, the diaphragmatis of Darwin.

The general symptoms are, pyrexia, pain in the chest, difficulty of breathing, cough; and, if the disorder happen in the sthenic diathesis, the pulse is hard and frequent. Sometimes the expectoration is tinged with blood.

The particular symptoms are, in carditis, palpitation, with unequal intermitting pulse, pain in the region of the heart, vomiting, fainting: if the inflammation be particularly directed to the diaphragm, the pain is situated towards the lower ribs, the respiration in a recumbent posture is extremely difficult, and the corners of the mouth are sometimes so retracted as to form a disagreeable smile, called risus sardonicus.

M. M. It is of the utmost importance to attend to the prevailing diathesis. If the constitution is sthenic, and the disorder urgent, immediate and copious bleeding. Refrigerant and emollient cathartics. Cool and equal, not cold and irregular, atmosphere. Diluent drinks. Total abstinence from animal food, sometimes during the first five days. Antimonial preparations. After venesection a blister on the pained part. Digitalis. In Dr. Currie's Medical Reports we find the following observations: "I have employed the digitalis to a very considerable extent in inflammations of the brain, of the heart, and the lungs; and have succeeded with it in cases where I otherwise should have despaired." In Dr. Reid's Treatise on Consumption we meet with an acquiescence in this sentiment on the fox-glove. Our experience, however, has taught us to value this remedy principally in other pulmonary affections than the more violent kinds of inflammation, as is mentioned under the head of phthisis. After the excitement has been moderated, opium in small doses. "Do neutral salts increase the tendency to cough?" Pediluvium. Small doses of calomel, to prevent adhesions.

N. B. If pneumonia run on into suppuration pus will be discharged by cough, and thus a species of consumption be formed; or will be detained in the cavity of the chest, and constitute empyema. In either case, digitalis in large doses. Calomel. Opium. Peruvian bark.

Genus VII. *Gastritis*, inflammation of the stomach.

Symptoms. Violent pain in the region of the stomach, with pyrexia; small, frequent, and sometimes contracted, pulse; vomiting; hiccough.

Causes. It may be occasioned by any thing acrid taken into the stomach; by blows on the region of this organ; and a slight species of it is often consequent upon taking cold liquids after exercise.

M. M. In inflammation of the stomach and bowels we have, in some measure, an exception to the general rule of cure, according as the disease appears sthenic or asthenic. The pulse and vital powers are often suddenly reduced, and yet venesection is required. Warm bath. Fomentations. Anodyne and mucilaginous clysters. Blisters on the pained part.

Genus VIII. *Enteritis*, inflammation of the bowels; fixed and distressing pain in the bowels. Pyrexia; pulse always quick, sometimes hard.

Causes. The same as of gastritis. Likewise strangulated hernia, spasmodic colic, intro-susception.

M. M. The same as in gastritis after the urgent symptoms have subsided. Small doses of calomel and opium.

Genus IX. *Hepatitis*, inflammation of the liver.

Symptoms. Pain in the region of the liver, extending to the clavicle and top of the right shoulder; difficulty of lying, on the left side especially. Pyrexia; high-coloured urine; pulse frequent, strong, and often hard. Bilious evacuations, or jaundice. The tendency of the disease is to suppuration.

M. M. Copious and repeated bleeding, before the suppurative process has commenced. Calomel, and cathartics of the refrigerant class. Digitalis in considerable doses. Blisters to the region of the liver.

If suppuration takes place, the matter makes its way through the lungs, or the intestinal canal, into the cavity of the abdomen, or through the peritoneum to the surface. During this process opium and bark.

N. B. The disease above described is principally an affection of warm climates. A species of chronic hepatitis is more usual in Britain, and indeed is one of our most common maladies, especially among dram-drinkers.

Symptoms. Obtuse and weighty kind of sensation in the region of the liver; difficulty of lying on the left side; pain in the right shoulder; the countenance slightly marked by hectic; dejection of spirits. Œdema of the ancles.

M. M. Small doses of calomel, with, or without, opium. Tonic bitters, such as quassia, or gentian. An abstinence from spirituous liquors.

Genus X. *Splenitis*, inflammation of the spleen.

Symptoms. Tension; tumor; heat of the left side; pyrexia; pain increased by pressure.

M. M. Blisters, cathartics, calomel, and digitalis.

Genus XI. *Nephritis*, inflammation of the kidneys.

Symptoms. Pyrexia; pain in the lumbar regions; retraction of the testicle; numbness of the thigh; vomiting; costiveness.

Causes. Alternations of heat and cold; external violence, &c. as in other inflammations, but chiefly calculi.

Distinctions. Nephritis is distinguished from lumbago by the more confined situation, and pungent character of the pain; by the presence of pyrexia; and by there being in the latter no retraction of the testicle, or numbness of the thigh. It is distinguished from incipient psoas abscess, by the pain of this last being principally seated in the vertebral column; by such pain being increased on pressure of this part; and by its taking the course of the psoas muscle. See SURGERY.

M. M. Venæsection. Digitalis, and opium. Nitrous æther. Emollient clysters. Castor oil. Demulcents.

Genus XII. *Cystitis.* Inflammation of the bladder.

Pyrexia. Pain and tumor above the pubes; pain in discharging urine; tenesmus.

M. M. Venæsection. Warm bath. Anodyne clysters. Diluents.

Genus XIII. *Hysteritis.* Inflammation of the womb.

Heat, pain, tension, and swelling in the lower belly; pyrexia; vomiting.

M. M. Venæsection. Mucilaginous clysters, with opiates. Anodyne fomentations.

Genus XIV. *Rheumatismus.*

Pyrexia; pains in the joints, frequently extending along the muscles; heat and tumor on the part.

Peculiarities. Rheumatic inflammations never, like others, terminate in suppuration. Dr. Darwin attributes this circumstance to the secondary and associate nature of the disease; the original cause, like that of the gout, not being in the inflamed part; and therefore not continuing to act after the inflammation commences. Perhaps the peculiarity would be more properly referred to the nature of the parts that rheumatism attacks.

Division. Rheumatism is sthenic, or asthenic: the latter, or chronic rheumatism, often succeeds to the former; which the author just quoted refers to the deposition of mucus, or coagulable lymph, which the inflamed vessels had poured out in the first stages, remaining unabsorbed on the membranes of the joints. It would probably be more correctly attributed to the loss of energy in the parts affected: an opinion which appears to receive support from the circumstance of the asthenic form of the complaint sometimes coming on in a direct way, without the intervention of the acute species.

M. M. Bleeding would appear to be indicated in the sthenic kind of rheumatism: in this disorder, however, the physician is so often unexpectedly foiled by the rapid occurrence of indirect debility, that venesection is almost never advisable; it lays the foundation for obstinate chronic complaint. Leeches to the inflamed joints. Volatile embrocations after the inflammation has in some measure subsided. Calomel, and opium. Sudorifics. Warm bath. "I have found digitalis an excellent remedy in inflammatory rheumatism, one of the most tedious and intractable of all diseases." Dr. Currie.

Peruvian bark in chronic rheumatism. Volatile tincture of gum guaiacum. Flesh-brush. Sea-bathing. Electricity. Bath waters.

Genus XV. *Odontalgia*, tooth-ache. See SURGERY.

Genus XVI. *Podagra*, gout.

Symptoms. Pain in the joints, principally of the great toe, and especially of the hands and feet, returning at intervals. Previously to the accession of the inflammation the functions of the stomach are generally disturbed. The fits generally come on in the morning.

Causes and peculiarities. Gout is invariably a disease of the asthenic diathesis. It is produced in a system predisposed to its influence by the indirectly debilitating powers; such as a too liberal indulgence in fermented and spirituous liquors, high-seasoned meats, &c. and likewise by the directly debilitating powers of vegetable and watery food, depressing passions, &c. The inflammation of this disease often alternates with, and appears in a manner vicarious of, torpor in other parts of the system; as of the brain producing apoplexy, the stomach constituting dyspepsy, and of the liver giving rise to jaundice: all which symptoms indeed may be considered as part of the disease. On this account gout has been divided into the atonic; that is, where a disposition to the inflammation of the foot is observable, but does not actually take place; the retrocedent, where, after the continuance for some time of such inflammation, it shall seem to be transferred to another part, and thus form a gouty inflammation of the stomach, or other organs; and, lastly, the misplaced, in which the gouty tendency, instead of displaying itself in its ordinary course, falls upon some other organs, as the lungs, the stomach, or the brain.

Dr. Darwin supposes "the original seat of the gout to be the liver, which is probably affected with torpor not only previous to the annual paroxysms, but to every change of its situation from one limb to another." For this principle of associate action there does not, however, appear sufficient support; and indeed the sympathy is displayed with more force and frequency between the inflamed foot and the organs we have above-mentioned (the stomach, the lungs, and the brain), than the hepatic viscus. It is indeed the nervous system, and not the glandular, with which the paroxysm of the gout appears to have the most intimate connection; and it would have found a more appropriate place under the head of nervous diseases, than where it now stands in the Nosology. It is, however, very often combined with calculary disorders. The predisposition to gout is evidently hereditary; but the attacks of this malady may, in general, be warded off, even from the most susceptible habit, by a temperate mode of living. This principle is illustrated in an extraordinary manner by the history of Dr. Gregory, the present professor of the practice of medicine in Edinburgh. We have often heard him in his lectures produce his own as an instructive case of the beneficial effects of abstinence from fermented and spirituous liquors. Gout has been imagined, like fever, to be a sanative process of nature for the purpose of expelling something from the constitution. The doctrine, in either instance, is equally erroneous.

M. M. In treating gout it should never be forgotten that it is an asthenic disease: while excitement is kept up in the system the paroxysms are suspended. Dr. Beddoes, in his Hygeia, says, that one of the greatest martyrs to gout he ever met with informed him, "that his freest year was that of a warmly contested election, at which he was candidate for a county. He both drank and exerted himself at this time more than at any period of his life." This evident principle of the asthenic nature, even of the actual inflammation in gout, ought to render the physician extremely careful in his application of the remedy lately introduced into practice, the application of cold water to the inflamed part. In some violent cases this may be proper; but it should never be extended beyond the limit of pleasurable sensation. To bleed is likewise hazardous in the extreme. Dr. Brown's mode of suspending the paroxysms has already been referred to; and every arthritic experiences temporary benefit from his dinner, his glass, and pleasurable company. It is by acting on the imagination that empirics suspend the threatened attacks of gout. In this, as in numberless other instances, faith in, constitutes the virtue of, remedies; both therefore in chronic rheumatism and gout, we might place among the curative agents metallic tractors, whether authorized by Perkins, or formed of old nails, as in the instructive experiments of Dr. Haygarth. Even a piece of sealing-wax, or stick, when supposed by the patient to be the genuine tractors, operated in a most astonishing manner. (Haygarth on Perkins's Tractors.) The influence of the imagination over the body, whether in health or disease, has not been sufficiently acted upon in the professional practice of medicine. The irregular affections in gout must be combated by stimulants carefully adapted to the excitability; for the spasmodic affections of the stomach aromatics and bitters, as ginger and quassia. If the head is affected camphor, musk, ether, opium; these likewise are remedies for the gouty asthma. The Portland powder, which is a composition of bitters and aromatics, may prove for a time highly useful; but the protracted use of medicines of this class is objectionable, as eventually detrimental to the stomach and general fibre. Regular and steady, and not capricious and merely temporary, abstinence from wine, spirits, and spices. The body to be preserved gently open. Pure air, moderate exercise, encouragement of cheerful habits. Warm and cold sea-bathing. Bath waters. Very small doses of digitalis. Hop (humulus lupulus)?

ORDER III.—*Exanthemata*, Eruptions.

The exanthemata are more nearly allied to genuine fever than those disorders of which we have just been treating, as the local affections are consequences rather than causes of the general irritation. They have been called eruptive fevers. They are defined by Cullen contagious diseases, affecting a person only once during the whole of life, commencing with fever, and succeeded by eruption on the skin. The contagious matter upon which these depend may indeed operate upon certain parts more particularly, and thus the disease be entitled to rank among the sensitive, irritative, or symptomatic fevers. This, however, is by no means certain: the primary action of contagion, whether of a specific or general nature, has hitherto escaped the penetration of the pathologist.

Genus I. *Erysipelas*, St. Anthony's fire.

Symptoms. This disease does not correspond with the whole of the above definition; it is not contagious; and it has frequently been found to recur. The face is the more ordinary seat of this affection. After febrile irritation has commenced, and continued for a short time, during which there is often an unusual drowsiness, and sometimes delirium, the face suddenly becomes bloated, the eyelids swell, and the skin is red and blistered. If the disorder is violent, or ill-treated, the inflammation and redness extend down the neck, and spread sometimes on the shoulders; the tumid appearance of the countenance increases, delirium supervenes, and the patient has been known to die apoplectic. The erysipelas is an erythematic inflammation. Its seat is the rete mucosum. Its tendency is to gangrene rather than to suppuration. A fatal termination is said to be principally on the 7th, 9th, or 11th days.

M. M. In no other affection is it of more urgent moment to decide on the treatment by the nature of the prevailing diathesis. It has been observed, that in large and populous cities St. Anthony's fire almost always appears in the form of asthenia; and in this case requires wine, bark, opium: while in the hardy constitution of the rustic it assumes a sthenic character, and demands the vigorous employment of what has been called the antiphlogistic regimen. Venesection. Saline purgatives. Diluent drinks. Might not digitalis be employed with a prospect of singular advantage, as the disease has an evident affinity with certain species of dropsy? With respect to external application, it has been customary to use mealy substances, such as flour. Solutions of lead, zinc, or alum, are improper, "as they stimulate the secerning vessels into too great action." (Darwin.) Cold water.

Genus II. *Pestis*, the plague, is an epidemic typhoid fever.

Genus III. *Variola*, small-pox.

Symptoms. After the pyrexial symptoms have continued for three days eruptions appear on the skin, which on the eighth day contain pus, and at length fall off in crusts.

Species. The small-pox is divided into the distinct, and confluent: the first has more of the sthenic, the latter of the asthenic, character. In the former the eruptions are of a phlegmonic, in the latter of an erythematic or spreading, nature. The eruption of the distinct small-pox makes its appearance in circumscribed red spots on the face; in the course of two days the body and legs receive their portion. The fever now ceases, the face swells, the pustules enlarge, and on the eighth day are mature. The swelling of the face now goes off, and the hands and feet begin to swell, with a slight return of fever, which however soon declines.

In the confluent, or asthenic, species, the fits are not so regular; the eruptions are not circumscribed and prominent, but diffused, and scarcely appearing above the skin; a kind of erysipelas sometimes precedes them, and every symptom denotes debility. The fatal termination is often on the 11th day.

Inoculation. The advantages of inoculation for the small-pox need not be insisted on. The circumstance, however, upon which depends the more favourable character of inoculated over natural small-pox, does not appear to have been satisfactorily accounted for. The only cautions requisite in preparing for inoculation, are to preserve the bowels free from sordes, and to choose a time for the insertion of the matter when teething, or other irritative processes, are not going on in the system. With respect to the time, it has been well said, that inoculation ought to be performed either before the second month, or after the second year.

M. M. Cold air. The bowels to be preserved open. Animal food to be denied. If the fever runs high, antimonials and nitre. In the confluent species, the alimentary and intestinal canal is with the utmost solicitude to be preserved free from congestions by purgatives, and the powers of the system supported by opium, bark, small doses of nitre, wine, pure air; vinegar aspersed about the bed, walls, and floor, of the apartment. Pediluvium.

N. B. For an account of the vaccine disease, or cow-pox, see the article VACCINATION.

Genus IV. *Varicella.* The chicken-pox is a very slight disease; the eruptions sometimes assume nearly the character of the distinct small-pox; but there is not much irritation of the system, and they generally disappear in the course of three or four days from their first breaking out.

Genus V. *Rubeola.* Measles.

Symptoms. Pyrexia, sneezing, inflamed eyes, dry cough, drowsiness; about the fourth day, or later, small red points appear on the skin, which in the course of about three days fall off in branny scales.

"As the contagious material of the small-pox may be supposed to be diffused in the air like a fine dry powder, and mixing with the saliva in the mouth to infect the tonsils in its passage to the stomach, so the contagious material of the measles may be supposed to be more completely dissolved in the air, and thus to impart its poison to the membrane of the nostrils which covers the sense of smell; whence a catarrh with sneezing ushers in the fever." Zoonomia.

M. M. Measles too often lay the foundation of pulmonary consumption, to prevent which the symptoms denoting inflammation of the lungs are to be with much solicitude obviated; and for this purpose small doses of tincture of digitalis are to be preferred to every other medicine. Venæsection cannot with propriety be used in young subjects, however imperiously called for; and digitalis supplies its place without the risk of inducing indirect debility. Steady and cool atmosphere, not cold air in currents. Refrigerant cathartics, with calomel. Animal food not to be given. Digitalis, with a very small quantity of opium, for the cough succeeding to measles.

Genus VI. *Miliaria*, miliary fever, is merely a symptomatic eruption of small red pimples about the neck and face, which in two days become white pustules, and desquamate. They have a peculiar smell. Much anxiety and difficulty of breathing precede the eruption. This disorder appears to be a consequence of an improper heating regimen in fever.

Genus VII. *Scarlatina*, scarlet fever.

Symptoms, &c. After pyrexia has lasted about four days a scarlet eruption appears on the skin, sometimes attended with inflamed tonsils and cervical glands: these last sometimes appear without cutaneous eruption, and the disease has been called cynanche maligna. This disorder is apt to be mistaken for measles; but in scarlet fever there are no catarrhal symptoms as in measles. This disorder is very irregular in its aspect; and often, without much care, fatal in its termination. Sometimes, without any alarming symptoms in the onset of the fever, a change takes place, and in the course of a few hours the patient falls into the arms of death. The unfavourable symptoms are the same as in other fevers. It is a disease principally of children. Whether it depend upon specific contagion, like measles and small-pox, is not perhaps fully ascertained.

M. M. Cold affusion. Cold air. Antimonials, opium, bark, wine, saline purgatives or enemas, nitre, blisters. See the section on Fever in this article.

Genus VIII. *Urticaria*, nettle-rash. After pyrexia for a day, small red spots, like the stinging of nettles, appear on the skin, which almost vanish during the day, but return in the evening. It scarcely requires any medical treatment. The disease does not last more than two or three days.

Genus IX. *Aphtha*, thrush. Spots on the fauces and tongue, by which this disorder is constituted, are almost always symptomatic of other diseased states.

Genus X. *Pemphigus*, "a fever attended by successive eruptions of vesicles about the size of almonds, which are filled with a yellowish serum, and in three or four days subside." The treatment is to be regulated by the nature of the attendant fever.

Order IV.—*Hemorrhagiæ* Discharges of blood.

The definition of this order is, pyrexia, with profusion of blood, without any external violence; blood when drawn from a vein shewing the buffy coat. Discharges of blood, however, are often unattended with pyrexical irritation, and indeed for the most part are evidences, not merely of local, but also of general weakness. Augmented energy in the larger propelling vessels may indeed overcome the resisting power of the smaller branches, and produce what is called active hemorrhage; in this case we have only local debility to contend with in the cure. Dr. Darwin divides hemorrhage into the arterial and venous, the latter of which he attributes to defect of venous absorption; it does not appear, however, that the veins act in the manner of absorbents, according to the opinion of our author. Venous hemorrhage depends upon general weakness, accidentally directed to the vessels from which the blood is poured out by rupture of their coats. It is always a highly asthenic disease.

Rupture of blood-vessels, and consequent hemorrhage, has been ascribed to an immediate and primary change effected in the constituent particles of the vital fluid. This supposition, however, seems to be totally unfounded; even in the most active hemorrhage the blood does not undergo "orgasm, ebullition, turgescence, or expansion," according to the theory of Hoffmann.

Genus I. *Epistaxis*, bleeding from the nose.

Symptoms. Pain or fulness of the head, giddiness, dimness of vision, drowsiness, irritation of the nostrils. It is the disorder principally of young persons, who have a lax and weak fibre; in some few instances it occurs as vicarious of obstructed menses, and sometimes appears in men when the hemorrhoidal discharge has been suddenly arrested.

M. M. Cold applied to the neck and head. Mechanical pressure, or absorbing substances, to the nostrils. Acids and astringents internally. Avoiding irritation of the body or mind. The bowels to be kept gently open. Nourishing but not stimulating aliment. In the epistaxis of old people, and in cases of much weakness, bark, vitriolic acid, opium. If the disorder is violent, and have depended upon the suppression of some other discharge, such discharge to be restored.

Genus II. *Hemoptysis*. Spitting of blood. Symptoms. Redness of the cheeks, a sensation of weight in the breast, difficult respiration. Saltish taste in the mouth, irritation in the trachæa, coughing up of florid blood.

Hemoptysis more usually appears in individuals with a slender make and contracted chest, who are of an irritable habit, and who have been subjected in their earlier years to epistaxis. It generally comes on at the age of puberty.

Causes. Violent irritation of mind or body, sudden vicissitudes of heat and cold, too powerful exertion of the lungs, as in singing, coughing, playing upon wind instruments. Like epistaxis, and indeed more frequently, it immediately originates from obstructed menses. Sometimes it appears vicarious of a gouty paroxysm.

M. M. All irritation and irregularities to be carefully guarded against. Bowels to be kept evacuated by mild purgatives. Manna. Tamarinds. Peruvian or oak-bark, combined with mineral acids, especially the sulphuric. Opium. Digitalis in large doses, so as to occasion nausea. "A table-spoonful of common salt." (Dr. Rush.) "One immersion in cold water, or a sudden sprinkling all over with cold water, would probably stop a pulmonary hæmorrhage." (Darwin.) Procure a return of the obstructed discharge.

Phthisis pulmonalis, consumption of the lungs.

Symptoms. Emaciation, weakness, cough, hectic fever, and for the most part an expectoration of pus.

Dr. Cullen has introduced pulmonary consumption into his nosology, as a sequel of hemoptysis. This common and fatal malady, however, often, and indeed for the most part, originates independantly of hemorrhage from the lungs. Its origin and progress are most usually exceedingly insidious. The persons chiefly obnoxious to phthisis, are those of a scrophulous habit, who have been disposed previously to suffer by lymphatic tumours, who are of a slender make, have long necks and narrow chests, who have been liable in their earlier years to bleeding at the nose, who have had frequent catarrhal affections while children, and in whom cough has remained or been ill-treated after the eruptive diseases of infancy, more especially the measles. These predispositions ordinarily break out into actual disease, at or shortly after the period of puberty. It is at this time that the pulmonary circulation becomes altered; and the seeds of the disease, hitherto latent, are expanded and developed.

In any constitution then at this period, and more especially in those that are characterised by a scrophulous tendency, a short and generally dry cough, succeeding perhaps to a trivial cold, attended with emaciation in the smallest degree, and more especially if the pulse be rapid, and the cheek be marked by hectic redness, alternating with more than usual paleness of countenance, the patient is to be assiduously watched, and the disorder earnestly combated.

Causes. Phthisical ulceration of the lungs, or confirmed consumption, is ordinarily produced through the medium of tubercles, or small bodies, in the cellular texture of these organs, which by repeated and gradual irritation, at length come to ulcerate and destroy the fabric of the lungs, and produce the symptoms of fully-formed phthisis. The origin and actual nature of these bodies are not perhaps very evident; they were formally erroneously imagined to be indurated lymphatic glands.

The more immediately exciting cause of pulmonary consumption is generally an exposure to cold, which operates in the manner described under the section Catarrh. Consumption, however, may be brought on by amenorrhœa, lues venerea, unseasonably repelled eruptive action on the surface, mental affections, &c.

M. M. "The facility," says a modern author, "of repressing the primary symptoms of phthisis pulmonalis, is proportioned to its difficulty of cure when the characters of the disorder are fully confirmed, and the texture of the lungs almost wholly destroyed." (Reid on Consumption.) In no case, perhaps, is neglect or early mismanagement of disease more pregnant with irremediable evils, than in the instance of consumptive affections. Digitalis properly and timely had recourse to is "the anchor of hope." "In families where this fatal disease (phthisis) is hereditary, the use of this remedy as a prophylactic, will, I have no doubt, save many lives that would otherwise have been cut short." (Dr. Currie.) "Digitalis is a remedy in pulmonary consumption in its earlier periods, which under due regulations, and with sufficient attention to other circumstances of regimen and diet, may be employed with a prospect of almost invariable relief." (Dr. Reid.) Other testimonies, equally decided, might be adduced in favour of this valuable remedy. Warm bathing. A regular temperature in the air that the person breathes. Warm clothing. Avoiding currents of air. Assiduously guarding against damp, and especially cold application to the feet, as by sitting with the feet on a stone floor, or an oil-cloth. Milk diet, of which Hoffman elegantly says, "Quà perplures phthisicos, in cymba Charontis quasi hærentes, sanatos, pristinæque redditos valetudini, novi." Avoiding all spirituous liquors, and spiced or high-seasoned meats. Keeping the bowels gently open by manna, castor-oil, senna, &c. Uva ursi has recently been recommended by Dr. Bourne.

These are the remedies of the first stage, or, more properly speaking, the menacing symptoms of consumption. When the lungs have actually become ulcerated after gradual and protracted irritation, very little expectation of recovery can remain. Griffith's mixture, composed of steel, myrrh, and alkali. Digitalis in larger doses, and combined with the above tonic. Uva ursi? opium and vitriolic acid. Digitalis combined with calomel. Change of climate. If a tendency to absorption from the surface of pulmonary ulcer could be induced greater than the deposition of it, we might have some prospect of curing the disease in its advanced stages. In order to produce this absorption, sailing so as to occasion sea-sickness has been had recourse to. Swinging, riding in a carriage, and other modes of occasioning a degree of vertiginous affection, and consequent nausea, have likewise been recommended and practised. Inhalation of a lowered atmosphere, of other modified gases, and even volatile astringent substances, have been also proposed and tried, but not with decided benefit. In the confirmed stages of phthisis, animal diet which is nutritive, without being stimulant, ought to be advised. Bath waters and cold seabathing are improper in every stage of the complaint.

N. B. If consumption be symptomatic of other diseases, while the symptoms are subdued by the above remedies, the attention must necessarily be turned principally towards the original affection.

Caution. All the signs of consumption may be present without the presence of the disease. Debility, emaciation, and cough, may be brought on by nervous, independant of organic disease, as well as by worms and intestinal viscidities. Hectic fever may be occasioned in certain constitutions by mental affections alone; this likewise is sometimes induced by worms. Purulent expectoration, indeed, is decisive; but the nature of the sputa is not with facility, in every case, to be decided upon.

Genus III. *Hæmorrhois*, the piles.

Weight and pain of the head, vertigo, pain in the anus and loins, swellings and flux of blood from the anus.

M. M. If symptoms of arterial activity accompany the hæmorrhoids, vitriolic acid, with moderate astringents, such as infusion of roses. Temperance, exercise, abstinence from spirituous liquors and spices. Tamarinds. Lenitive electuary, sulphur, chrystals of tartar. Castor oil. Warm fomentation, by sitting over the steam of heated water. Leeches. These two last remedies, are especially serviceable in what are called the blind hæmorrhoids, where there is swelling with pain from congestion in the hæmorrhoidal veins, without any discharge of blood from the anus.

When the hæmorrhoidal flux is attended with much debility, while the bowels are kept open by castor-oil and other similar purgatives, the more powerful astringents are to be employed. Steel. Exercise. Generous diet. Cheerful train of thinking. See SURGERY.

Genus IV. *Menorrhagia*, immoderate menstrual flux.

Symptoms. Pain in the back and loins, vertigo, difficulty of breathing, flushes of heat and cold, frequent pulse; in cases where the disease is more directly from debility, loss of appetite, paleness of countenance, coldness of the limbs, œdematous swellings about the ancles.

M. M. In the first species, the menstrual irregularity generally arises from hysteric or nervous affections, libidinous desires, and other violent passions; in this case attention must be paid to counteract the cause. Avoid stimuli of all kinds, mental or physical. Refrigerant cathartics, if costiveness be present. Moderate astringents, such as infusion of roses, and the sulphuric acid. In the menorrhagia of direct debility, astringents, cordials, and stimulants. Peruvian bark and sulphuric acid, opium, alum, port wine. External application of cold water, or vinegar. Steel. See MIDWIFERY.

ORDER V. *Profluvia.*

The profluviæ are distinguished by Dr. Cullen from hemorrhages, by the discharges not being naturally sanguinary. This order contains two genera, catarrhus and dysenteria, both of which might have found more appropriate situations even in Dr. Cullen's own nosology.

Genus I. *Catarrhus*, a cold.

Symptoms. Pyrexia, with increased discharge from the muccus membrane of the nostrils, and in violent cases of the fauces and bronchiæ, with cough.

The term cold, which is made use of, in common language, principally to denote an inflammatory condition of the mucous membrane of the nose, is exceedingly incorrect; it not only confounds the effect with the cause of the disorder, but conveys an erroneous idea of the mode in which such disorder is created.

The operation of cold, unless through the medium of the sensations, is invariably negative; it is merely an abstraction of the stimulant power of heat, and by its application to the living body (from an invariable law of organic existence) renders the frame in a more than ordinary measure susceptible of such, and other stimulant powers. For example: Suppose an animal to exist in a medium temperature of 60°, let 10° be subtracted for a short period, and afterwards precipitately added, the 60° will now act as with a power, perhaps, of 65, on account of the previous abstraction of stimuli producing, as it has been very properly expressed, "an accumulation of excitability." In this manner then is explained the agency of cold, in engendering inflammatory disorders, among which that we are now considering is one of the most frequent; an explanation founded upon a principle for the developement of which we are unquestionably indebted to the genius of Dr. Brown. This author, however, made an improper use of his own discovery; he did not sufficiently take into account the complicated and combined functions of the animal economy; and the very first position which he deduced from the detection of this important, and indeed, characteristic, quality of living existence, is practically incorrect. "Cold applied to the animal system never proves injurious unless succeeded by heat:" frigus nunquam nocet, nisi ubi ejus actionem calor excipit. In endeavouring to support this assumption, Dr. Brown and his disciples have aimed to prove that those symptoms which are usually characterised by the appellation of a cold, as well as rheumatism, and all other diseases arising from exposure to cold, are not occasioned until the same or a superior degree of external heat be restored; forgetting that the "accumulation of excitability" immediately resulting from diminished temperature is acted upon, and thus inflammatory irritation engendered, by the remaining stimuli of the frame, external and internal. Thus an individual, while still exposed to the catarrh-producing temperature, while, for example, his feet remain wet and cold, shall have inflammation in the mucous membrane of the nose and fauces, febrile irritation, and all the usual phenomena of catarrh; the balance of excitement being overturned, and turbulent irritant action being established in its stead.

Further, the existence of a cold does not suppose the presence of a sthenic disease: indeed the exact contrary is the fact, for the malady will be occasioned with most facility when the frame is weak and irritable.

Why the membrane of the nostrils, &c. should be the readiest to suffer more particularly, does not seem to admit of an easy explanation; it is important, however, to recollect what has been pointed out in an explicit manner by Dr. Beddoes, and since by Dr. Reid, that this membrane is a part of the same expansion with that which lines the windpipe and enters the lungs; so that in fact a common inflammatory cold is a degree of the same disease with an inflammation of the lungs.

M. M. Moderate and equal temperature. The bowels to be kept gently open. If the febrile irritation is considerable, sudorifics. Antimonials, nitre. Oleaginous substances may be used to allay the cough; but irritating balsams, such as cough medicines are generally composed of, are in the highest degree detrimental; they too often increase the disposition to, and sometimes actually produce, confirmed consumption. Liquorice, honey, boiled fig, almond emulsion.

If the phthisical tendency is conspicuous, digitalis (see the section on Phthisis pulmonalis).

Genus II. *Dysenteria*, dysentery.

Symptoms. Frequent stools, mixed with mucus, and sometimes with blood, attended with griping and tenesmus, the proper alvine excretions being retained; pyrexia, pulse quick and feeble. The disease is sometimes contagious and epidemic.

Causes. Dysentery depends upon the irritability of weakness, determined by particular circumstances to the alimentary canal; its predisposing and exciting causes are alternations of heat and cold, more especially when accompanied by damp, as when an army is encamped on marshy ground; the putrid miasma arising from the marshes; the contagious effluvia proceeding from the discharge in the disease; and, according to sir John Pringle, from dead bodies left unburied in the field of battle.

The immediate cause of the symptoms seems to be, a spasmodic construction of the larger intestines, retaining the fæces.

M. M. Calomel, opium, and rhubarb, to relieve the spasm, and discharge the contents of the bowels. Mucilaginous clysters, as of starch with tincture of opium. Emetics. Small doses frequently repeated of ipecacuan. Colombo. Peruvian bark. Warm bathing.

CLASS II. *Neuroses*, Nervous diseases.

Man is indebted for all his acquisitions to casual observation, leading to experiment. That the faculty we call the sentient resided in, or was developed through, the instrumentality of a peculiar and distinct organization, we should not, a priori, have conceived; there is nothing in the composition either of brain or nerve to lead to this conjecture. If, however, a portion of the bony defence of the encephalon be accidentally pressed in upon its substance, and an interruption in the faculties of sensation and voluntary motion be the consequence; if such accident be repeated with the same result; finally, if it be found, as it has been, that by voluntarily producing pressure on this organ, similar effects may be occasioned in proportion to the degree and extent of the force employed; the inference will come at length to be indisputable, that the brain is the organ or reservoir of sensation, and the medium through which loco-motion is effected.

Again, if it be found that at pleasure we can deprive any portion of the body both of sense and motion, by dividing the nerve supplying such part, or cutting off its communication with the brain, we are likewise fully justified in inferring, that the chord we have severed was the instrument by which the empire of the will had been exercised over the now inert and useless member.

It is by the aggregation of such observances that we arrive at the pathology of nervous, as a distinct class of morbid affections. When, for example, any particular member of the body suddenly refuses to obey the command of the will, or, in common language, becomes paralytic, although we may not be able to trace the remote cause from which this has originated, we know that it must have immediately depended upon some morbid change, either in the brain itself, or at least in the nerve supplying the organ indisposed.

This mode of inferring the nature of what is not an object of our senses, by comparing it with what we actually observe, will be found equally satisfactory, in relation to partial as total interruptions of sense and motion; thus, by a less degree of injury done to a nerve, as by lacerating or puncturing, instead of dividing it, we shall perceive not an entire deprivation of, but merely an impediment to, the loco-motive faculty; the actions of the member will be in a manner refractory; and convulsive or irregular, instead of orderly and steady, motion, will follow the mandates of the will.

If then, without the interference of an experimenter, and without visible injury to the animal structure, the movements of an organ become improperly accelerated, or cease to be exercised in their usual mode; if, to instance by example, the heart perform two feeble, in place of one full and vigorous contraction; we are authorised to state, that the disorder thus constituted is strictly and properly a nervous affection; and our conclusion, as to the fact, will be precisely the same, whatever theory we incline to, respecting the quo modo in which nervous power is displayed; whether with Hartley we conceive it to depend upon vibrations and vibratiuncles, whether we embrace the doctrine of universally pervading æther, or subscribe to the untenable positions of the author of Zoonomia.

Depraved perception and interrupted motion, are therefore the essences of nervous disease: the percipient, however, is to be distinguished from the motive faculty; for we have a class of living actions, which, although equally under the influence of nervous power with those over which the will presides, are nevertheless, in a state of health, incessantly carried on without perception or consciousness; thus, by impeding the functions of the nerves of the stomach, we may interrupt the function of digestion. Digestion, however, is a process performed without design, and independantly of volition; on the other hand, the intellect may be impaired by a derangement in the nervous system, while the digestive power shall proceed without the smallest hindrance.

Dr. Cullen's definition of a nervous disease, would therefore have been more accurate, had he stated it to be an affection of either sense or motion, without idiopathic pyrexia, or visible disease of parts. The orders of this class (neuroses) are four:

1. Comata. A diminution of voluntary motion, with sleep or impaired senses.

2. Adynamiæ, a diminution of the involuntary motions of either natural or vital functions.

3. Spasmi, morbid motions of muscular fibre.

4. Vesaniæ, disorders of the judgment or intellect without primary pyrexia, or observable affection of any particular part of the body.

Order I. *Comata.*

Genus I. *Apoplexia*, apoplexy.

Symptoms. Abolition of the sentient and loco-motive faculties, the sleep in general attended with snoring. The respiration, motion of the heart, and other involuntary actions, remaining.

Causes. We conclude from the analogy above-stated, that there is some degree of pressure on the brain in almost all cases of apoplectic stupor; but that effusion of blood takes place in the manner described by the generality of authors, is exceedingly problematical; if the appearances on dissection are appealed to in behalf of this theory, it is answered, that such appearances can alone apply to fatal cases of the disease; and in such, an actual rupture of vessels and effusion of blood will readily be admitted.

Epilepsy, palsy, and apoplexy, were contended by Brown to originate from the mere irregularity of nervous power consequent upon debility or deficient excitement; and to be occasioned without either an unusual impetus of circulation to the vessels of the brain, or impeded return of blood from this organ. We believe, however, that although the cause of apoplexy often is in one sense mere deficiency of excitement directed to the sentient organization, the immediate occasion of the apoplectic symptoms is for the most part the state of the vessels of the brain.

Apoplexy, for the sake of illustration, may be divided into sthenic and asthenic. If a vigorous and plethoric man, sitting down to his dinner and his glass, suddenly, during the excitement of conviviality, of mirth, and of alcohol, fall on the floor with deprivation of sense and apoplectic stertor, it must be evident that the fit has been induced by a greater flow of arterial blood into the vessels of the brain, than the veins of this organ could, in due time, convey away. The apoplexy has been induced in the manner of a sthenic disease.

If, on the other hand, a debauched and debilitated individual be the subject of an apoplectic attack, at the time when the excitement of intoxication shall have been succeeded by the condition of indirect debility, the disease will here have been brought about in a different manner; the impetus in the vessels of the brain shall have partaken of the general diminution of power throughout the whole system; sluggish vascular action shall have caused congestion; which congestion, in union with the deficient excitement on which it had depended, shall have induced that sudden suspension of the sentient faculty which constitutes the apoplectic paroxysm.

Apoplexy often immediately succeeds to a full meal: what more natural than, under such circumstances, to attribute the fit to a distended stomach pressing upon the aorta or large descending blood-vessel, and consequent determination of the vital fluid in an inordinate measure to the head? Such conclusion, however, will not bear the scrutiny of strict enquiry. Upon this principle, the apoplectic stertor and insensibility ought to be induced with most readiness, as in oneirodynia or night-mare, while the body is in a recumbent posture, and the stomach is most distended from the extrication of gas which takes place in consequence of the weakened digestive power; in place of this, however, the fall is immediate; the attack is made while the body is in an erect position, and often before the stomach has become in a very great degree distended; the fit then arises, in this last case, from that degree of excitement which the digestive powers have called off to their aid, leaving the brain in a condition of insufficient energy, properly to propel the vital fluid through its own vessels; congestion of blood is the consequence, and this last the proximate or immediate cause of the fit.

M. M. The strictest attention to the manner in which the disorder has been brought on. If the disease is sthenic, and the physicians are called in while the paroxysm still continues, immediate and copious bleeding from the arm, the jugular veins, or the temporal artery. Every ligature about the patient's body, especially about the neck, to be loosened immediately. Press hard with the thumb and fore-finger upon the carotid arteries, taking care to avoid the jugular veins. Place the head of the patient high on his pillow, or seat him erect in a chair. Preserve the apartment cool. Cold water may in some cases be applied vigorously to the forehead and temples. Afterwards saline purges, and subacid drinks. Enemas. Careful preservation from irregular and violent excitations, either of body or mind. In the asthenic, and by far the most usual form, of the complaint, bleeding with much less freedom and only during the paroxysm; in general, it is not at all proper. It is better to open the temporal artery, if convenient, than to bleed from the arm or jugulars. The application of cupping-glasses still preferable; apply blisters to the neck. When the power of deglutition has returned, cordials and stimulants. Opium and wine in very small doses. Volatile alkali. Sprinkle vinegar about the room. To prevent the returns of the fits; tonics, particularly bitters, as colombo, gentian, quassia; exercise and mental amusement, without violent excitation. Journeys to Bath or elsewhere. Preserve the body regularly open, without violent purgations. Avoid sudden exposure to cold, especially cold and wet feet. If the fit has followed the suppression of any accustomed discharge, or cutaneous eruption, let them, if possible, be restored.

Genus II. *Paralysis*, palsy.

Partial interruption of the loco-motive faculty, sometimes with a degree of apoplectic stertor.

This is partial apoplexy, arising from similar causes operating in a less degree. It sometimes succeeds to a full fit of apoplexy, and continues for months, or during life. The palsy often affects the whole of one side, and is confined to that side; hence it has been supposed, that the injury of the brain is likewise partial; and from the decussation that has been imagined traceable of the nerves from the encephalon, Dr. Darwin and others have concluded, that the origin of the disease is on that side of the brain opposite to the affected side.

Palsy, however, certainly originates at times (even if genuine apoplexy does not) from interrupted excitement, without any congestion in the brain, as its more immediate source; as when it results from the poison of lead and other causes.

M. M. Ascertain the exciting cause, and, if possible, counteract it. Emetics, purgatives, preceding stimulants and tonics. Tonics and stimulants the same as in asthenic apoplexy. Volatile embrocations to the paralyzed side or limb. Warm bath. Bath waters. Electricity. Galvanism.

N. B. Fatuity, or second childhood, very often takes place through the medium of paralytic affections; the faculty of memory appears to be overthrown by the associate sentient actions, which constitute this faculty, being dissevered beyond the power of reunion; and existence is reduced, in consequence, to a state of mere vitality from immediate impression. This is not seldom the case when the loco-motive power, and the energy of the muscular fibre, shall have been restored to their former state. In this case the recollection of the past, and anticipation of the future, have both probably been irrecoverably lost.

The mere possibility of his being reduced to this condition of humiliating existence, one would think a motive sufficiently powerful to check the intemperate in his course.

Order II. *Adynamiæ.*

Genus I. *Syncope*, fainting.

Symptoms. A diminution, or even, for a time, a total cessation, in the action of the heart.

Fainting may arise from passions of the mind; from sudden reduction of stimulus, as from bleeding, or drawing off the waters in dropsy; violent pain; the irritation of worms, or other crudities, in the stomach and bowels; much heat, offensive effluvia, &c.: in these cases the disorder has been called syncope cerebralis. When fainting arises from deficiency of oxygen in the circumambient air, as in a crowded assembly, the cessation of the heart is produced nearly upon the same principles as in actual suffocation, drowning, or strangling. It is then termed syncope pulmonea.

M. M. Immediately obviate, if possible, the exciting cause. Endeavour to restore sensation by aspersing cold water on the face and neck; attempt to force down a small quantity of brandy; and in all cases, but more especially when the affection arises from impure air, throw open the windows, and prevent compassionate spectators from crowding round the insensible patient.

N. B. If fainting, or palpitation, recur frequently, and without any manifest cause, either predisposing or exciting, there will be reason to suspect that the disorder is not nervous, but depends upon some malconformation in the heart, or neighbouring blood-vessels. In this last case it is irremediable.

Genus II. *Dyspepsia*, indigestion.

Symptoms. Deficient, or depraved, appetite; nausea; vomiting; inflation from flatulence; heartburn; pain in the stomach, especially when the body is in a bent position; oppressed breathing; costiveness.

This disease evidently arises from deficient action in the muscular fibres of the stomach, which in violent cases amounts to inverted motion and vomiting. It acknowledges the same sources as other affections of weakness: these are, intemperate use of spirituous liquors, and of tea; exposure to damp and cold; irregular hours of repose; intense study; mental depression and anxiety; when originating from this last source the disorder has an equal claim to the appellation of hypochondriasis, or low spirits, with that of dyspepsia.

M. M. Purgatives, with calomel, previously to giving tonics. An emetic. Columbo, gentian, quassia. Magnesia, in order to neutralize the acidity, and ease the consequent pain of heartburn.

Chalk, which is used with the same intention, is improper, on account of that neutral compound which it forms with the acid of the stomach being insoluble, and tending to increase the costive state. "The dyspeptic must be persuaded that a horse is the best physician; and that temperance of every kind, with reasonable dissipation and exercise in a dry healthy air, will do more for him than all the medicines in the world." (Townsend.) Cold, or shower, bath, in very warm, and warm bathing in cold weather. A glass of warm water after dinner and supper.

Genus III. *Hypochondriasis*, low spirits.

Indigestion, with languor, and causeless apprehension of evil, more especially as it relates to the patient's state of health.

This disease and dyspepsia only deserve to be distinguished by separate names, inasmuch as the mental depression in hypochondriasis appears especially to increase the disease by which it is, in part, constituted; and such disease is again magnified beyond measure by the morbid imagination of the invalid. Thus, in some cases of confirmed hypochondriasis, the dyspeptic sensations shall be attributed by the sufferer to the immediate agency of a malevolent power.

M. M. Aim at converting solicitude and apprehension into confidence and hope; not by deriding the feelings of the hypochondriac, and treating them as fanciful, but by breaking the chain of diseased associations. Procure a gradual change of scene and of habits. Journeys to Bath, or elsewhere, according to the previous disposition of the patient. Bath waters. Warm bathing. Preserve carefully the alimentary canal free from colluvies and viscidities by drastic purges and calomel. Maintain a regular moisture of the skin, without copious perspiration. Tonics with aromatics. Dr. Darwin particularly insists, and with justice, on the advantage of uniformity in the hours of meals: this uniformity should even extend to medicinals, the same hour of repetition being invariably observed. "Siesta, or sleep after dinner."

Genus IV. *Chlorosis*, green-sickness.

Dyspepsia; paleness of the skin and of the lips; lassitude; difficult breathing, and palpitation of the heart, after using more exercise than usual, especially in going rapidly up stairs; pulse small, feeble, and sometimes very quick; coldness of the extremities; appetite deficient, and oftentimes depraved; pain in the back and loins; costiveness; œdematous ancles, especially towards evening; and obstructed menstruation. "Chlorosi laborat debilis puella totum corpus, laxo œdemate tumet; pallent et frigent omnia." (Van Swieten.)

Dr. Cullen has, with much impropriety, classed this among the nervous diseases; it ought to have been transferred to the next leading division of disease, or rather regarded as an affection of the lymphatic and absorbent system. In cases of much debility, especially of disposition to torpor, in the absorbent and secerning vessels; if, at the time when nature demands a new secretion and discharge from the system, in place of generous living, due exercise, moderate and pleasurable excitation of the mind, "the ever-springing hope" of youth, &c. be substituted to poverty and unwholesomeness of diet, watery and vegetable food, inactivity; concealed, oppressing, ungratified, and hopeless desires; the effect is the disease now under notice: which, however, from much natural debility, independantly either of mental depression, unwholesome diet, or any other cause, may be, and very often is, occasioned. Chlorosis, indeed, is of exceedingly frequent occurrence.

The immediate cause is evidently an inactive state of the absorbent vessels, more especially of those which supply the chyle: hence deficiency of red blood in the vessels, want of propelling power in the heart and arteries: hence want of menstruation, œdematous swellings of the feet, "pallent et frigent omnia."

M. M. Almost as certainly as some kinds of pain yield to opium, does even obstinate chlorosis fall before the power of steel. "Dum hoc utitur, incipit oriri major calor." To steel, then, must the physician principally trust in every case of genuine green-sickness. It is necessary, however, frequently to commence with an emetic; and in almost all cases it is proper to give a purgative, joined with calomel, before the administration of steel. Tonic bitters. Aromatics. Moderate exercise in a pure atmosphere. Flesh diet. "A bath of about eighty degrees, as Buxton;" not by any means colder. Marriage.

Order III. *Spasmi*, Spasms.

In the introduction to the class Neuroses, we endeavoured to describe briefly the manner in which a knowledge was acquired of the separate functions and distinct diseases of the nervous system. In the case of spasmodic affections this is especially illustrated. If in any animal the nerve supplying a limb be denuded, and a violent stimulus be applied to its surface, the whole member shall be immediately thrown into convulsive agitations: a fact which is perhaps too often demonstrated in galvanic and other experiments. When then such convulsive movements appear, without experiments, and sometimes without apparent cause, a similar change is justly inferred to take place in the nerve or nerves passing to the organ which may be the subject of the disease. There is one circumstance with respect to spasm that, both in theory and practice, ought always to be retained in the memory; this is, that the spasmodic or convulsive state of parts invariably implies debility. To act irregularly, is in all instances to act with deficient vigour; for the sum total of these disorderly movements, performed in a given time, will not amount to the quantum of power displayed in the same time by healthy and steady action. This fact appears to be a sufficient refutation of Dr. Darwin's hypothesis, that convulsions are voluntary exertions of the muscles to relieve pain, even if we concede to this author, that the strict definition of volition ought to be "the active state of the sensorial faculty in producing motion, in consequence of desire or aversion, whether we have the power of restraining that action or not;" for, according to this principle, convulsion should be an actual and positive increase of vigour, which it is not; for while the utmost agitation is carrying on in the convulsed member or organ, if a due quantity of stimulus be thrown in, excitement will immediately follow, and in consequence of this excitement, quiescence and firmness; in the same manner, but upon a different principle, as tightening the sail of a ship arrests its vibratory motions, but increases its actual and integral force.

If it appear difficult to conceive why a stimulant or exciting agent should produce this debilitated action, we must refer to the invariable law of living existence, that excitation carried beyond a certain point, is immediately productive of indirect debility: thus when the galvanist convulses the leg of a frog, he throws in more of stimulus than is adapted to the fibrous excitability of the organ in question; he exhausts the irritability of the part; and the convulsion that follows is the consequence of such exhaustion, exactly upon the same principle that half a pint of wine shall give steadiness to the tongue, and firmness to the step, while a quart of this stimulus, taken in the same time, shall produce a temporary paralysis of the limbs, and render the speech faultering and inarticulate.

We have indiscriminately employed in the above observations, the terms spasm and convulsion. As it relates to the excitement, they are virtually the same states; and thus, whether convulsion or spasm, that is, whether rigid immoveable contraction, or rapid alternations of contraction and relaxation, follow the debilitating causes upon which they depend, in one sense they are scarcely to be distinguished; the difference of physiognomy which they assume appears to have dependance upon the complicated associations of living actions, which are but little understood, and both in theory and practice too much disregarded.

From the above remarks we hope it has been rendered evident, that in attempting to overcome a spasm or convulsion, the leading principle of cure must be stimulative; the disease in question, however originating, invariably implying debility, or more properly, perhaps, deficiency of excitement.

Sect. I. *Spasmodic affections in the animal functions.*

Genus I. *Tetanus.* A spasmodic rigidity of a great part of the body: in some instances it is drawn violently backward, at others forwards, and in both cases the disease is generally followed or attended by trismus or lock-jaw; these symptoms may last with greater or inferior violence from twenty-four hours to a month or more.

The immediately exciting causes of tetanus are, wounds or pricks of tendons; the sudden application of cold after extreme heat; great intemperance, or other vices: the disease may likewise be consequent upon viscid mucus, worms, and other irritating substances, in the alimentary passages.

M. M. As in fevers, it is highly necessary to preserve the alimentary canal free from colluvies, in order that the return of due and orderly excitement may not be prevented by this cause; so is it especially necessary in nervous and spasmodic affections carefully to keep in mind the incalculable importance of this principle. Indeed, among the actually exciting causes of the malady now under notice, these intestinal crudities are perhaps the most frequent. Let the practitioner then, in every spasmodic disorder, pay solicitous attention to the condition of the stomach and bowels: it is in these organs "that the archer may be seated," in whatever directions he may send out his arrows. It is not, let it be as carefully remembered, by the act of evacuation in reducing the system, that either emetics or purgatives operate thus beneficially; but by the disposition that a freedom in the first passages favours to the due susceptibility of the exciting powers, on the agency of which the return of health depends. Indeed, as far as either purging or vomiting are in themselves immediately instrumental in dissolving spasm, as it has been expressed, independantly of the source just referred to, it is by virtue of the agitation and stimulus, not by the discharge of which they are productive. (See Infancy.) Emetics, cathartics with calomel. Pouring large quantities of cold water over the body during the spasm, in order forcibly to sever the catenated motions by which it is constituted. Warm bathing. Very large quantities of opium. More than four hundred drops of the tincture have been given in some violent tetanic affections in the course of twenty-four hours, and without producing any intoxicating effect. Other antispasmodic medicines. Mercury. If the spasm has originated from a lacerated or punctured tendon, divide it freely, and produce pain and inflammation.

Genus II. *Convulsio,* convulsions. On the cause and treatment of these, we need not enlarge, after the remarks we have introduced on the nature, predisposing and exciting causes, of convulsive and spasmodic disorders in general.

Genus III. *Chorea,* St. Vitus's dance.

Symptoms. Convulsive agitations of the limbs, in general almost confined to one side of the body. When the patient attempts to walk, he produces involuntary gesticulations.

M. M. Emetics, cathartics with calomel; anthelmintics; bark, steel, and other tonics; electricity, galvanism, tepid bathing, sea-bathing.

Genus IV. *Raphania,* contractions in the joints.

Symptoms. Spastic contractions of the joints, with excruciating pain, and convulsive motions, returning periodically, and continuing for many days. It appears to be a species of rheumatism.

M. M. Purges, followed by tonics; mercury combined with opium.

Genus V. *Epilepsia,* epilepsy. Violent convulsions of the muscles, attended with sleep.

Epilepsy in its nature and causes appears to hold a kind of intermediate situation between apoplexy and convulsion; it has the sudden fall and the sopor of the one, with the irregular muscular action of the other. Epilepsy, in a greater or less degree, is a disease of extreme frequency: indeed, all the convulsions of children may be called epileptic. In its full and formidable shape, it is not so frequently met with as several other diseases. A physician, however, may denominate, with propriety, all fits epileptic, of which alternate or combined convulsions and sleep constitute the characters, especially if these are connected in any degree with an increased action of the salivary glands.

M. M. Epileptic fits are sometimes congenital, hereditary, and depend upon some occult state of the nervous system. In these cases the disorder is generally irremediable. All that can be done by art is merely to ascertain, and endeavour, if possible, to obviate, the exciting causes of the disease; and during the paroxysm to loosen every bandage about the neck and head, preserve the apartment in which the fall is made as airy as possible, and be careful that the patient do not inflict injury upon himself by the violence of his agitation. In some cases, indeed, the individual can obviate the full formation of the paroxysm by tying a ligature round the limb in which the sensation threatening the attack is perceived, between the point at which such sensation commences and the brain. This sensation constitutes what is called the epileptic aura: its abstract cause is obscure; but no less so than the phenomena of spasm in general.

In treating the complaint, particular attention is to be given to the predisposing and exciting cause or causes, which are extremely numerous; such as youthful intemperance, indulgence in secret vices, mental passions and affections, imitation of other epileptics, lively recollections of previous impressions, repelled eruptions or discharges, sudden alternations of the extremes of temperature, unpleasant odours, and, as by far the most common source of those epileptic fits which scarcely amount to absolute epilepsy, worms. These causes must all necessarily be removed before the physician can have the least prospect of overcoming the disease. Emetics, cathartics, with calomel; anthelmintics: suddenly dissever the chain of associations, by plunging the patient in the cold bath, or dashing with violence cold water over his naked body. Induce a new disease, as the itch; a plan which Dr. Darwin adopted with success in the treatment of St. Vitus's dance, with which the present has a great affinity. Patients have likewise been cured of epilepsy, by the accidental occurrence of a quartan ague. These are instructive cases to the reflecting and speculative. Tonics. Galvanism. By this newly discovered source of nervous excitation, the writer of this article recollects to have witnessed a supposed cure of a very obstinate case of epilepsy. It is not, however, easy to ascertain how far remedies operate in overcoming gradually, chronic affections.

Of Worms, and Anthelmintics. Worms we have just stated to be among the most frequent of the exciting causes of epileptic fits. As the order of our nosology no where leads us to notice them in an especial manner, it may not be improper in this place to introduce one or two remarks respecting their nature and treatment.

Intestinal worms are of three kinds: the ascaridis, or small thread-like worm; the lumbricus teres, or round worm; and the tænia, or tape worm. The first of these are principally confined to the rectum: they are divided by Dr. Darwin into two species, viz. "the common small one, like a thread, which has a very sharp head, as appears in the microscope, and which is so tender that the cold air soon renders it motionless; and a larger kind, above an inch long, and nearly as thick as a very small crow-quill, and which is very hard in respect to its texture, and very tenacious of life." The symptoms by which the presence of these may be suspected, are an uneasiness and itching in the rectum, especially urgent towards evening: this, if violent, disturbs sleep, and occasions febrile irritation, and sometimes tenesmus, with mucous discharge from the anus, indigestion, and itching of the nostrils.

M. M. Clysters of lime-water, injection of tobacco-smoke. Mercurial ointment introduced into the anus. Aloes and steel, both by the mouth and in the form of enema. Saline purgatives. Harrowgate water, so as to induce six or seven stools every morning.

The lumbricus is the most common. Its symptoms are enumerated in the article INFANCY. Lumbrici are of very different lengths and magnitude; they are principally found in the smaller intestines, but are situated occasionally both in the stomach and larger intestines. These worms have been known to pierce through the coats of the alimentary canal, and have thus occasioned most excruciating pains and death.

The tape worms are sometimes voided of an enormous length: they have been stated to be from two to forty feet long. They properly consist of an united chain of separate animals; as, when broken, each portion has the power of reproduction. "The worms of this genus possess a wonderful power of retaining life. Two of them, which were voided by a pointer dog in consequence of violent purgatives, each of which was several feet in length, had boiling water poured on them in a bason, which seemed not much to inconvenience them. When the water was cool, they were taken out, and put into gin or whisky of the strongest kind, in which their life and activity continued unimpaired, and they were at length killed by adding to the spirit a quantity of corrosive sublimate."

The symptoms are much the same with those of the lumbrici, but more urgent.

M. M. See MATERIA MEDICA, section Anthelmintics.

Spasmodic Affections continued.

SECT. II. *In the vital Functions.*

Genus I. *Palpitatio,* palpitation. See Syncope.

Genus II. *Asthma.*

Symptoms. Difficult respiration returning at intervals, with a sense of tightness across the breast. Wheezing at the commencement of the asthmatic fits; scarcely any cough but what is hard: towards the close of the paroxysm it however becomes more free, attended with a discharge of mucus.

These symptoms certainly arise from a spasmodic construction of the bronchial fibres, "which is communicated by consent to the larynx and diaphragm."

The causes of asthma are numerous, while its predisposition is often hereditary, and dependant upon a peculiar conformation and temperament; the actual disease may be excited by intemperance either in eating or drinking, violent exercise, mental agitation, eruptions or discharges abruptly or unseasonably repelled; the fumes of metallic poison, as of lead, &c.

M. M. Spasmodic asthma, when fully established, scarcely admits of a radical cure. The paroxysms to be relieved by opium and æther; coffee; tonics in the intervals, principally of the class of bitters and aromatics. Avoid distending the stomach inordinately. Emetics; enemas previous to the expected accession; gentle horse exercise; pure air; oxygen gas. If eruptions have been repelled, endeavour to restore them.

Genus III. *Dyspnœa,* difficulty of breathing. This is improperly introduced into the nosology as a genus, it being merely a symptom of other diseases, consequent upon defective formation of the chest, or brought on by evident causes, which being removed, the disorder immediately declines.

Genus IV. *Pertussis,* hooping cough.

Symptoms. Convulsive strangulating cough, with noisy inspiration or hooping, and sometimes attended with vomiting. It is contagious.

The precise nature, or, as physicians express themselves, the proximate cause of hooping cough, does not seem to have been accurately ascertained. Dr. Darwin supposes it to be "an inflammation of the membranes which line the air-vessels of the lungs, and that it only differs from peripneunomia superficialis in the circumstance of its being contagious." He on this account enumerates it among the sensitive irritated fevers: we are inclined, however, to think that the infection principally operates upon the stomach; and that the inflammatory disorder of the mucous membrane is merely a consequence of the protraction, or erroneous treatment, of the complaint. It is not attended, in the first instance at least, with the symptoms of inflammatory irritation; and the vomiting, by which the violent fits are often relieved, proves that the stomach, in pertussis, is in a morbidly irritable state.

It deserves however to be remarked, that the membrane in question is very apt to partake of the prevailing irritation, to become inflamed, and thus, like the inflammation after small-pox, and measles more especially, to lay the foundation of consumption of the lungs.

M. M. Antimonial emetics. Very small doses. Warm bathing. Above all, digitalis; in no disease, perhaps, is the power of this valuable medicine displayed more forcibly and evidently than in hooping cough. Its effects are generally almost instantaneous. After the violence of the disease has subsided, and even before, change of air. Cicuta (conium maculatum) has been much employed in this complaint.

SECT. III. *In the animal functions.*

Genus I. *Pyrasis.* Water-brash of Scotland. Water-qualm.

Symptoms. Sudden eructation of watery fluid with or without heartburn; the fluid brought from the stomach sometimes insipid.

M. M. The author of the present article recently had an opportunity of witnessing in this disease the beneficial effects of the inhalation of tobacco-smoke by a person not previously accustomed to smoking; this man had taken tonics, antispasmodics, and antacids, without effect. "A grain of opium twice a day, soap, iron powder, a blister." (Darwin.)

Genus II. *Colica,* colic.

Symptoms. Permanent and excruciating pain in the belly, with a sensation as of twisting about the navel, constipation, and sometimes vomiting.

Causes. These symptoms evidently originate from spasmodic constriction in some part of the intestinal canal, which may be occasioned by various causes; such as indigestible food, the sudden application of cold; acrid substances received into the stomach; poisons, especially lead; hence colic is a kind of epidemic disease among painters, attended with paralysis of the arms, &c. It is likewise common in cyder countries.

M. M. Opium. Cathartics, principally of castor oil. Warm bathing. Anodyne clysters. Fomentations and blisters to the part. In obstinate cases of the painters' colic, Bath waters. Carefully obviate the exciting causes of the disease.

Genus III. *Cholera.*

Symptoms. Vomiting and purging of bilious matter, violent pains in the stomach and bowels, with great anxiety and irritability.

Cholera is one of the diseases of the autumnal months; it is very often produced by the sudden succession of cold to unusually warm weather: it sometimes follows the taking of indigestible substances, as of much cold cucumber, especially at the period of the year above-mentioned, when the directly debilitating power of cold abruptly succeeds to the indirectly debilitating operation of heat, and the biliary secretion is more than ordinarily copious.

M. M. During the violence of the vomiting and purging, give water-gruel, and inject starch clysters, to each of which add tincture of opium. After the disorder has in some measure subsided, restore due excitement by cordial and nourishing diet, with stomachic medicines. If febrile irritation is induced, the saline draught, composed of salt of wormwood and lemon-juice.

Genus IV. *Diarrhœa.*

Symptoms. Frequent stools, without primary pyrexia, and not induced by contagion.

A morbid action in the excretories of the intestines constitutes this disease: sometimes however, and frequently, purging arises from mere loss of excitability in the intestinal fibre, without increase either of bile or any other excretion. It is immediately occasioned by acrid matter in the intestines; by acidities, by mental passions, or by the sudden application of cold, more especially to the feet.

M. M. According to the exciting causes. If there is reason to suspect the lodgment of acrid matter, calomel, with jalap, senna, or rhubarb Afterwards astringents, of which one of the best is good red wine. Opium. Chalk, if acidity prevails. An emetic if the disorder continues obstinate.

Genus V. *Diabetes.*

Symptoms. Superabundant discharge of urine, in some cases amounting to fifty pounds in twenty-four hours, limpid and sweetish to the taste, with urgent and perpetual thirst, dry skin, weakness, emaciation.

This disease often, perhaps, exists to a very considerable extent without being detected. It is not an uncommon complaint among the poor, especially of the north of Britain.

The principal circumstances that have attracted the notice of the pathologist in reference to this complaint, are the saccharine quality of the urine evacuated, and the attendant emaciation. One of the principal ingredients in the nutrition of the body has been supposed to be the saccharine principle; from the inordinate discharge of this principle in the diabetic urine, the disorder has been therefore referred by some to a deficiency of assimilating power in the stomach and digestive organs, while others have imagined it to originate entirely from altered action in the kidneys. Perhaps both of these causes may operate in producing diabetes. Upon dissection, the kidneys are always found flaccid. Dr. Darwin, after Mr. Charles Darwin, attributes the copious flow of urine to the inverted or retrograde action of the urinary lymphatics; but besides that this theory does not account for the superabundance of sugar or of mucilage in the water, it has been proved that such inversion of the absorbents is inconsistent with their structure and general economy.

M. M. Animal diet. Dr. Rollo and others have observed that when the patient lives on animal food, the saccharine quality of diabetic urine abates. Alkaline and astringent medicines, such as nut-galls and lime-water. Bark. Steel. Opium. Alum-whey.

N. B. A copious flow of urine is frequently observed to attend nervous affections, and indeed is one of the characteristics of the disease we are next to notice: in these cases however, the water has not the superabundance of the saccharine principle as in genuine diabetes, which last disorder has been erroneously placed in the class Neuroses.

Genus VI. *Hysteria.* The hysteric disease.

Symptoms. A gurgling of the bowels, followed by globus hystericus, or a sensation of a ball ascending to the throat, and menacing suffocation. Convulsive agitations, alternate laughing and crying, a general fickleness and irritability of mind. A large quantity of straw-coloured or limpid urine. Hysteria, like epilepsy, is in a certain degree extremely common; it generally first occurs in females about the time of puberty. It is, like all other convulsive affections, a symptom of a lax habit, and is consequent upon the irritability of weakness. It may be brought on by mental agitation, or by irritations in the stomach, bowels, uterine organs, &c.

The discharge of urine which attends or precedes hysteric paroxysm, is attributed by Dr. Darwin to the inverted motions of the lymphatics about the mouth of the bladder, as in diabetes; a temporary torpor, or spasm of these vessels, would appear sufficient to account for the superabundant excretion, the watery part of the urine not being taken up.

M. M. Avoid every occasional and exciting cause of the disease. Bark, quassia, and other tonics. To remove the present symptoms, camphor, assafœtida, castor, opium; if this last, from idiosyncracy, disagrees with the patient, the hyoscyamus will generally be found an excellent substitute. This has not the constipating tendency of opium; and in hysteric cases it is of importance, while much evacuation is guarded against, to preserve a freedom both in the alvine and cutaneous discharges. Emetics. N. B. The customary plan of bleeding in hysteric affections is extremely detrimental to the general health, and disposes to a return of the paroxysms. If it is judged necessary in some cases of hysteria to withdraw a small quantity of blood, it should be done not by venesection in the ordinary mode, but by the application of a cupping-glass.

Genus VII. *Hydrophobia.*

A dread of water as exciting painful convulsions of the pharynx, caused for the most part by the bite of a mad dog, violent spasms, furious insanity, death.

M. M. "When the contagion of a putrid fever is taken by the saliva into the stomach and bowels, which is its constant road," (query) "if the patient the moment he finds himself attacked with a sense of chilliness, loss of appetite, and an unpleasant taste in his mouth, has recourse to two emetics at proper intervals, and after the operation of the first emetic takes a cathartic, he has certainly got rid of the infection: in the same manner, even after three days, or perhaps a week, if the part bitten by the dog be cut out with the knife, the danger is escaped." (Townsend.) Dr. Thornton advised the application of hot vinegar, sharpened with vitriolic acid, to the wounds of five men who had been bitten by a rabid animal, and this application was attended with seeming success. Mercury: this by some has been extolled as a specific for hydrophobia.

Order IV. *Vesaniæ.*

Disorders of the intellect, independant of pyrexia or coma.

"Every nervous disease, (says an author whom we have before quoted) is a degree of insanity." If, however, imagination carried to the height of sentient perception, or, as it has been expressed by Dr. Batty, the raising up in the mind of images not distinguishable from impressions on the senses, is the proper definition of the insane state—"the cardinal point on which madness turns"—the above apophthegm of Dr. Reid may be regarded as rather bold and impressive than strictly accurate. It were surely improper to denominate the apoplectic, the paralytic, the hysteric, or the tetanic, insane; yet an individual under these maladies, is as truly affected with a nervous disorder as one who, like the lunatic astronomer in Rasselas, conceiting himself to possess the mastery of the elements, commands rain to shed fertility on the barren soil.

That the disorders of the intellect are disorders of the nerves we readily admit, it is the converse of the proposition we presume to question; and in so doing, we justify Dr. Cullen, in considering the vesaniæ, or mental affections, as a distinct order of nervous diseases.

The pathology of such diseases is peculiarly perplexing. We find by experience, that an increase of vascular action in a tender organ will give rise to the feeling of pain; we have ascertained by the conjunctive and mutually reflective aid of casual observation and direct experiment, that convulsive movements in the muscular fibre are occasioned by an interruption of nervous excitement in whatever that may consist; we see the brain pressed upon, and the apoplectic stupor follow; but in endeavouring to trace deranged consciousness to disordered organization, temporary or permanent, an increase of intricacy appears in a manner to grow out of labour and research.

Dissection does not afford that assistance to the pathologist in this, as in many other departments of his inquiries; for, independantly of the great want of uniformity that has been observed in the brains of the unfortunate victims to mental derangement, it is impossible to judge from an inspection of this organ, how far the altered structures and appearances have been causes, and how far consequences, of the malady.

Dr. Cullen has four genera in his order vesaniæ, viz. amentia, melancholia, mania, and oneirodynia, on each of which we shall introduce a few remarks.

Genus I. *Amentia*, ideocy.

Amentia is defined an imbecility of judgment, preventing the perception or the recollection of the relations of things.

Man is born with merely a susceptibility of knowledge, a capacity of acquisition; he is conducted from observation to comparison, and from comparison to principle. Place an infant in a spacious apartment, give him for the first time the free use of all the senses with which nature has furnished him, and he will stretch out his hand to perhaps the most distant object in the room, with a full persuasion of being able to grasp it. Like the youth couched by Cheselden on Epsom Downs, every thing within the scope of his vision appears in a manner to touch his eye, he has not the smallest conception either of distance or magnitude, and the same total ignorance prevails in respect to objects which have relation to all his other senses. Knowledge then is the result of experience, which is another word for comparison or observation of "the relations of things."

As man, however, essentially differs from the brute, by the more extended compass of his intellectual grasp, the superinduction of the moral sense, and the anticipation of future events, so different individuals have varied susceptibilities of acquiring information; and this variation, which constitutes every shade of difference in intellectual character, must necessarily arise either from difference in the perceptive organs, or combining and retaining faculty. When then, without any apparent deficiency of the external senses, which are the inlets to knowledge, we find an individual not to have arrived at a given standard of intelligence by the constant employment of such senses, not to have obtained a due knowledge of "the relations of things," we place him out of the range of intelligent existences, have an obscure conception of something defective in the interior structure of his sentient organization, and denominate him an ideot.

This is the amentia congenita of Cullen, ideocy from birth.

Ideocy, however, may be produced. Fatuity may succeed to intellectual vigour, and the whole fabric of acquired knowledge be undermined and overthrown. Thus man may be literally reduced to the humiliating condition of second childhood. This state may be engendered abruptly and visibly, or gradually, and almost in an imperceptible manner. It may follow violent agitations of the frame, as desolation succeeds to tempest, or may be brought about by the gradations of natural decay.

The causes of ideocy, when it is not the result of original malconformation, are, all kinds of intemperance, more especially indulgence in the use of spirituous liquors: "it has been traced up to somnolence too much indulged." The media through which it is principally occasioned are mania, apoplexy, and above all epilepsy. When firmly established even in youth, very little hope of recovery can be entertained by the friends of the unfortunate victim to his own imprudence. The condition of ideocy is a condition beyond the reach either of physical or moral influences!

Genus II. *Melancholia.*

Genus III. *Mania.*

We have placed these two genera of Dr. Cullen together, as we deem our author fundamentally erroneous in considering them distinct affections. Melancholia is defined "partial madness without dyspepsia." From this mode of reasoning, mania, instead of being distinguished by the character of universal madness, would have been with as much propriety denominated partial madness without fever.

Insanity is intensity of idea, converting imagination into implicit belief, and thus producing an incongruity of action; incongruity as it respects former, consistency as it relates to present, impressions and associations. It partakes of the character of mania or melancholia, of violent rage or gloomy despondency, according to the previous temperament of the sufferer, and the nature of the prevailing idea. In each the disordered associations are engendered upon precisely the same principles.

Madness differs from ideocy, as the conclusions derived from erroneous principles, in philosophising, differ from the conceptions of ignorance: the one is correct reasoning from erroneous premises, the other is defective judgment from defective information.

How this intensity of idea is produced, we have no means of ascertaining: we do not indeed feel it difficult to comprehend, that an absorbing attachment to one object, or an exclusive attention to one particular pursuit, may come at last to make shipwreck of the understanding; but it is the susceptibility of being carried away by this idea, that constitutes the difficulty in question. Like the developement of intellectual character, the disposition to run into the state of insanity may perhaps depend upon the most minute circumstances of accidental associations: "Il ne faut qu'un leger accident, qu'un atome déplacé, pour te fair périr, pour te dégrader, pour te ravir cette intelligence dont tu parois si fier!" So precarious is the tenure, even of the most exalted possessions of man!

Madness, however, like ideocy, may be produced through the medium of bodily disorders; thus, fever will often occasion delirium, which is a species of temporary insanity. Thus, an obstruction of the menstrual discharge will frequently be the means of developing the latent disposition to maniacal disorder, occasioned by previous disease, resulting from erroneous education, or depending upon hereditary conformation. Indeed, almost the whole range of nervous diseases may, under predisposing circumstances, come to be exciting causes of genuine insanity. When lunacy has been brought on by bodily disorder, the complexion of the derangement shall be formed by the previous temperament, or natural disposition, of the sufferer; thus, the favourite ideas of health shall, in their increase, be the predominant and overwhelming ideas of madness; again, when the insane state has more immediately proceeded from passions of the mind, or moral rather than physical causes, the idea that has vanquished the intellect shall continue to reign. The imaginary monarch shall preserve his dominions and sway, and through the medium of his distempered fancy, shall observe menials and attendants in the persons who surround him; the melancholy lover shall require but a female form to pass before his cell, to be persuaded of the actual presence of the object of his affections; and the religious enthusiast shall read a special embassy from heaven, in the countenance of every compassionate visitor.

Prognosis. "The chances of recovery are against those madmen, who can trace their indisposition to lunatic ancestry. When the causes are accidental, or obviously corporeal, a favourable termination may be expected. "The insanity subsequent to parturition, is generally curable if the curative attempts be rational." (Cox.) "Patients who are in a furious state recover in a larger proportion, than those who are depressed and melancholic. When the furious state is succeeded by melancholy, and after this shall have continued a short time the violent paroxysm returns, the hope of recovery is very slight. Indeed whenever these states of the diseased frequently change, such alteration may be considered as unfavourable. When insanity supervenes on epilepsy, or where the latter disease is induced by insanity, a cure is very seldom effected." (Haslam.) "When a person becomes insane who has a family of small children to solicit his attention, the prognostic is very unfavourable, as it shews the maniacal hallucination to be more powerful than those ideas that generally interest us the most." (Darwin.) "Though individuals of every temperament become insane, it has been observed that those of the sanguine more frequently recover."

M. M. Endeavour to draw off the mind from the prevailing idea, or otherwise to convince the maniac of the errors of his conceptions, and fallacy of his pretensions, by relating the incongruous conceits of other maniacs which have some affinity with his own. M. Pinel states, that in the Bicétre of Paris, a maniac was cured of the hallucination of supposing his head had been taken off by the guillotine, and that another had been placed on his shoulders, by a person judiciously ridiculing in his bearing the miracle of St. Dennis, who was said to carry his head under his arm, and to kiss it. When the maniac was endeavouring to prove the possibility of the fact by an appeal to his own case, the narrator of the story suddenly exclaims, "Why, how, you fool, could he kiss his own head? was it with his heel?" In incipient and equivocal madness, cautiously abstain from expressing suspicions in the hearing of the patient. "Nothing is more calculated to make a person mad than the idea of being thought so." (Reid.) On this account, premature confinement is to be deprecated, not merely as cruel, but as injudicious in the extreme. Those who are placed over the insane as guardians, should unite decision and firmness of character with tenderness of disposition and gentleness of manners.

In strong plethoric habits, venesection. Cathartics. These last, especially in melancholy, often require to be of the drastic kind, and united with calomel. "Diarrhœa very often proves a natural cure of insanity." (Haslam.) Vomits. Camphor. Opium in large doses. Cold bathing during the violence of the paroxysms, and in some cases warm bathing in the intervals. During the urgency of phrenzy, apply cold water to the head. Clay cap. Blisters to the scalp. In some cases the production of a vertiginous state by a rotatory swing, has lately been found effectual in breaking the morbid associations constituting phrenetic and melancholy paroxysms. Digitalis in very large doses, but regulated with care. Introducing a new disease, which is of a trivial nature, and easy of cure. "I should place considerable hopes on inoculation, had the party not previously had the small-pox, taking care, by proper medicines and management, to increase the symptoms that usually attend this last disease to such a degree, that the whole system should be considerably affected without the life being endangered." (Cox.)

In instances where madness has originated from corporeal diseases, it scarcely requires to be observed, that a considerable part of the treatment must be constituted by the administration of those remedies that in common cases of these affections have been found to be effectual.

Genus IV. *Oneirodynia.* This genus is defined by Dr. Cullen "a violent and distressing imagination in time of sleep." It is divided into two species: the active, or that exciting to walking and various other motions; and the gravans, with a sense of weight or pressure on the chest. This last is the incubus of authors, or night-mare, which is doubtless placed erroneously among the disorders of the judgment.

The former of these is generally either congenital, or induced by unknown causes; it is perhaps principally curious, as it evinces the almost unlimited power of one sense, when concentrated as it were, or employed to the exclusion of the rest. Dr. Darwin relates the case of a gentleman who had lost his sight, entering his room, and immediately informing him of the length, breadth, and height of the apartment, by the undivided exercise of his sense of hearing; an accuracy which he could not have arrived at, had he retained the faculty of sight. In like manner the sleep-walker "will unlock his door, wander far from home, avoid opposing obstacles, and pass with safety over narrow bridges," which during his waking hours he would have shunned as unable to accomplish.

The incubus, or night-mare, appears to arise from an interruption of the circulation of blood through the lungs, from defective irritability in these organs, induced by fatigue, mental oppression, "a full supper, and wine;" which last, in some persons, will almost invariably induce the disease.

M. M. Temperance; especially moderate suppers. "To sleep on a hard bed with the head raised." Emetics. Purgatives of aloes and calomel. Tonics. Sleeping in a large airy apartment, and without curtains to the bed.

Class III. *Cachexiæ.* Cachexies.

Previously to an acquaintance with the distinct structure and separate functions of the nervous system, before the important discovery of the circulation of the blood, and the more recent, but hardly less important, developement of the anatomy and physiology of the secerning and absorbent vessels, the notions of pathologists on the mode in which disease, local and general, is occasioned, were indistinct and erroneous.

When, for example, on the surface of the body appeared a peculiar eruption, which after a certain time broke through the outer skin, and discharged an offensive matter, it was natural to infer that such discharge was engendered from a depraved condition of the solids or fluids of the living system, nearly in the same manner as exhalations proceed from dead and putrid animal or vegetable substance, or as wort is formed in the fermenting vat. Hence the use of the terms bad habit of body, foulness of blood, peccancy of humours, cachexies.

These gross and indiscriminate opinions respecting the actual nature and immediate cause of disease, are now retained alone by the vulgar; and as the nomenclature should keep pace with the advances of science, the word cachexy, as descriptive of those affections we are now to notice, ought to be banished from the phraseology of the nosologist, and a generic title substituted, indicative of disordered or deranged action in the secerning, absorbing, and glandular organs.

Order I. *Marcores.*

A wasting of the body or general emaciation.

Genus I. *Tabes.* Asthenia, emaciation, and hectic.

Genus II. *Atrophia.* Asthenia, and emaciation without hectic.

Dr. Cullen has properly distinguished the emaciation connected in its origin with hectic fever, from that independant of this as a primary and essential character. The latter, however, or atrophia, should not appear in the last class of diseases. When, for example, in consequence of mental affection, of sudden and too copious evacuation of any of the fluids, of deficiency in the quantity or depravation in the quality of the articles of diet, a loss of flesh and strength is perceived, the effect shall have been occasioned without any default in the absorbent vessels, and consequently without hectic; for let it be retained in the recollection, as a principle of the utmost importance in practice, that where hectic fever is present, a greater or less degree of derangement in the lymphatic vessels is likewise present. Hectic fever is a disease of the absorbent system.

For the purpose of illustrating this distinction between tabid and atrophic disorders, let two individuals be supposed equally emaciated and equally weak; but this weakness and emaciation in one shall have been induced by an indisposition to take a due quantity of nourishment, in order to supply the requisitions of the frame; in the other perhaps, notwithstanding the loss of bulk and of strength, an equal, or even greater quantity of aliment shall have been received into the stomach. Now, in this latter case, the tabid state has been occasioned by a torpid condition or improper action of those vessels whose office it is to separate the nutritive part of the food, and convey it, properly prepared, to the blood-vessels (see the article Digestion). In the former the mischief has proceeded from a want of those materials upon which these vessels exercise their functions. In the one the hectic flush from the very onset of the malady shall imprint the cheek; in the other, hectic will not be occasioned until the absorbents, from not being properly exercised, come at length to be disordered. The one complaint is the tabes of Dr. Cullen; the other is the atrophia of the same author.

We have been particular in pointing out this distinction, because it is not sufficiently noticed by writers in general, notwithstanding its extreme importance in practice; and because, by keeping it distinctly in view, we shall be enabled to reconcile the apparently contrary operation of those medicines which are employed with varied effect under different circumstances of debility and emaciation.

Steel, for instance, is one of those articles which, on account of their almost magic power over some diseases of debility, have been indiscriminately recommended in all; it has acquired the erroneous appellation of a tonic medicine, but as a tonic it often fails.

Now let us trace its effects in the two species of emaciation just alluded to. In the first stage of atrophy its administration will be often followed by irritative action, in the place of due excitement; the attendant febrile heat (not hectic fever) will be augmented, costiveness and an arid skin will follow, and indeed all the symptoms of the malady be heightened and confirmed.

In tabid diseases, on the other hand, the reverse effects will arise. Here the fever is hectic; and in the same degree that this valuable medicine, when duly employed, had increased the febrile irritation in atrophia, it will assuage the fever of tabes, and from the same cause, the stimulus which it imparts to the absorbent and lacteal vessels.

How hectic fever originates, it is difficult to explain: its symptoms have been attributed by a writer of the present day to that overplus of excitement being expended upon the arterial, which is occasioned by the deficient excitability of the absorbent system. This, however, is rather a statement than an explanation of its essence. The characteristics of hectic are principally the circumscribed redness on the cheek appearing more evidently once or twice in the course of the day, usually after meals, and alternating with a more than ordinary paleness of countenance; the pulse is feeble and quick; like the crimson flush of the cheek, it is accelerated by any thing received into the stomach; the urine is for the most part high-coloured, but deposits a bran-like sediment after standing for some time; the tongue is not furred in the same manner as in fever in general, but is clean; and often, as the disease advances, it increases in redness, the exact contrary to what is observed in genuine fever; the sweats are partial and irregular, and not attended with the same degree of temporary relief as in other cases; and, more especially in the advanced periods of the complaint, principally break out about the neck, breast, and shoulders; as the disease proceeds, debility and emaciation succeed, the legs and feet become œdematous, and (not however till nearly the fatal close of the malady on which the hectic depends) delirium at length supervenes.

M. M. In atrophia, a supply of nourishment, equivalent to the loss that may have been sustained; if emaciation has arisen from mental disturbance, the remedies must chiefly be made to apply to the mind. Tonics from the vegetable class, such as colomba, quassia, and gentian; not steel. Abate the febrile irritation, by keeping the bowels gently open by the milder purgatives, such as manna, senna, and castor oil. Preserve a slight moisture of the skin by small doses of antimonials. Regular and moderate, not violent or agitating, exercise. Shower-bath in very warm, tepid bathing in cold weather. Pure air.

In tabes, or emaciation, accompanied by primary hectic. An emetic, to accomplish the double purpose of forcibly expelling ventricular and intestinal acidities, and exciting the languid absorbents. Drastic purgatives, as jalap or aloes, with calomel, with the same intention. Steel, in conjunction with Peruvian bark or bitters. Horse exercise. Warm bathing.

N. B. Tabes is for the most part symptomatic of other complaints, as of a disease of the lungs or the liver; and in such cases the treatment by which it is to be overcome is the treatment of the original or radical malady.

Order II. *Intumescentiæ, general swellings.*

Sect. I. *Adiposæ,* Fatty swellings.

Genus I. *Polysarcia,* obesity. This arises from the deposition of oil in the adipose membrane becoming disproportionate to the requisitions of the body. It proceeds in general from indolence and intemperance.

M. M. Temperance, exercise, less animal food, early rising.

Sect. II. *Flatuosæ*, windy swellings.

Genus I. *Pneumatosis*, a tense elastic swelling of the body, crepitating under the touch.

Pneumatosis is constituted by a distension of the cellular membrane from air; it may arise without any evident cause, and in this case is denominated by Dr. Cullen the spontaneous pneumatosis; or the distending air may be introduced by means of an external wound, as of the thorax, in compound fracture of the ribs: sometimes elastic swellings of the whole body follow, from the application of poison; and at others, pneumatosis appears as an attendant upon the hysteric disorder.

The pathology of this disease, unless when it arises from wounds, is exceedingly obscure.

M. M. Scarifications, compresses, tonics.

Genus II. *Tympanites*, a windy swelling of the abdomen, tense, elastic, painful, and attended by costiveness.

Tympanitic swellings, both of the intestinal canal and of the cavity of the abdomen, often take place in conjunction with anasarca, or other disorders of debility, and frequently arise from sedentary habits, hypochondriac ailments, and innutritious diet.

M. M. Carminatives, emetics, tonics, and a generous diet, with exercise.

Tympanites is sometimes connected with obstructed menstruation, and in this case is seldom overcome but with the return of the menstrual discharge.

Genus III. *Physometra*, an elastic swelling in the hypogastrium, consequent upon flatulent distension of the womb.

"This frequently deceives the barren female with the hopes of pregnancy, till nature explains the mystery, and her expectations vanish in air."

Sect. III. *Aquosæ*, watery swellings.

Dropsical enlargement is distinguished from pneumatosis by its being inelastic, or pitting from the pressure of the finger, and slowly recovering its former fulness.

While considerable obscurity attends the nature and proxmiate cause of windy swellings, the theory of dropsical affections is sufficiently evident. Dropsy is a collection of serous fluid, either in the cellular membrane, or in the cavities of the body. It is invariably occasioned by exhalation being disproportionate to absorption; this increase of exhalation and diminution of absorption result from debility, which may be either direct or indirect; the latter follows increased action of the vessels, as in the dropsy succeeding to intemperance; the former arises out of deficient excitement in the lymphatic system, as when an individual becomes dropsical from indolence, inactivity, mental depression, and poverty of diet. Partial dropsies, or anasarcous swellings of the cellular membrane, as well as effusions into cavities, may also originate from pressure on the veins; independantly of original debility in the lymphatic vessels, such pressure obstructing the free reflux of blood through the venous system, and by consequence occasioning a more than ordinary determination to the exhalant arteries in the vicinity. Such are the dropsical accumulations which sometimes occur in pregnancy, and which are relieved by delivery. In this manner likewise, that swelling of the abdomen, constituting ascites, partly originates, when it is caused or attended by an obstructed circulation through the liver, the blood in the vena portæ accumulating in an inordinate measure, and by consequence supplying the lymphatic vessels of the part with more than their due proportion of fluid. Lastly, without universal debility in the exhalant and absorbent vessels, dropsical swellings may arise from inflammation, as is illustrated in the anasarcous collections following erysipelas, in the hydrocele succeeding to a blow on the testicle, in the dropsy of the chest resulting from inflammation of the lungs, and in ascites following peritoneal inflammation.

In whatever mode, and to whatever extent, dropsy may be occasioned, the accumulation of serous fluid by which it is constituted, always argues debility in the lymphatic vessels of the part in which this accumulation occurs. This debility, perhaps, is primarily and principally seated in the lymphatic exhalants; for we do not find hectic fever a characteristic of hydropic, as it is of other affections, in which an original torpor of the absorbents is evidently the cause of the morbid symptoms. Hectic only comes on in the last stages of dropsy, when the absorbents are worn out with constant exertion to absorb the effused fluid.

We have hitherto spoken indiscriminately of dropsy of cavities, and of dropsy in the cellular membrane: these, however, although they often exist conjointly, require to be distinguished; for instance, an accumulation of water in the thorax may be confined to the cellular texture of these organs, and form the disease properly distinguished by the denomination of anasarca pulmonum; or it may be diffused in the cavity of the chest, and constitute the true hydrops pectoris, or hydrothorax. The former generally arises from an universal torpor of the lymphatic system, and is almost constantly connected with hydropic swellings of other parts, particularly the ancles and legs; the latter often originates as a local disease, as from an inflammation of the pleura, and is sometimes confined entirely to the chest.

Genus I. *Anasarca*. General dropsy.

Dropsy of the cellular membrane immediately under the skin appears principally in the lower extremities, on account of the depending situation of these members, and the universal connection between the cells of which the membrane is constituted; and party on account of the deficiency in lymphatic excitement, from which it originates, being more conspicuous in those vessels which are the furthest removed from the centre of the circulation. Anasarca, as it arises from exhausted excitability in the lymphatic vessels, is always a disorder indicating much danger.

M. M. Those stimuli which are found to exert their influence on the absorbent vessels, particularly steel, digitalis, calomel. Diuretics, such as squills, juniper, nitrous æther, cantharides, chrystals of tartar, and nitre. Emetics and cathartics are less proper in anasarca than in dropsy of cavities. The physician must be especially careful while evacuating the fluid by means of diuretics, to support the general excitement, in order to prevent its reaccumulation; from want of solicitous attention to this particular, the waters, after an apparent cure of anasarca, often again collect to an increasing extent. Punctures and scarifications of the extremities are seldom advisable, on account of the prevailing debility and tendency to gangrene.

The sparing use of liquids is generally proper in dropsy; instances, however, have been known of copious draughts of water producing a termination of the complaint.

Genus II. *Hydrocephalus*, dropsy of the brain. See Infancy.

Genus III. *Hydrorachitis*, dropsical tumour in the spine. See Surgery.

Genus IV. *Hydrothorax*, dropsy of the chest.

Symptoms. Difficulty of breathing, especially in a horizontal position, paleness of countenance, starting in sleep, palpitation of the heart, numbness of the arms, especially when elevated, and in the advanced stages of the malady an evident fluctuation of water in the cavity of the chest. The hydrothorax, or hydrops pectoris, "is distinguished from the anasarca pulmonum, as the patient in the former cannot lie down half a minute; in the latter, the difficulty of breathing, which occasions him to rise up, comes on more gradually; as the transition of the lymph in the cellular membrane, from one part to another of it, is slower than that of the effused lymph in the cavity of the chest." (Darwin.) We have already said, that in the anasarca pulmonum the disease is often attended with swelled legs. Dr. Darwin suspects that even this species of dropsy of the chest is in the greater number of instances a disease merely of the cellular membrane of the part, not of a general torpor of the lymphatic system, and that the legs do not swell till the patient, from the protraction of the local malady, becomes universally weak. We often, however, meet with ascitic and anasarcous swellings commencing in the extremities, which, in their course towards a fatal termination, rise up into the chest, and in this manner occasion the pulmonic affection. Here the general paralysis of the lymphatics precedes the primary disorder of the thorax.

Causes. Where the universal has preceded the local affection, the malady is most frequently to be traced to intemperance in the use of fermented and spirituous liquors. The most usual source of genuine hydrothorax, or hydrops pectoris, is the sudden application of cold, while the body is in a state of perspiration and debility, from previous heat and exercise. Young people, during perspiration and fatigue from dancing, "if they drink freely of cold lemonade or water are apt to bring on a dropsy of the chest." (Townsend.)

M. M. Digitalis in considerable doses is especially indicated in dropsy of the chest, and its effects are more visible as well as more certain in the anasarca pulmonum than in the hydrops pectoris, because this medicine influences powerfully the whole extent of the absorbent system. Squill, in combination with calomel, for the hydrops pectoris; and if the cellular membrane be anasarcous, connect steel with both the above medicines. Chrystals of tartar, especially in the anasarca pulmonum. Diuretics of other kinds, the same as in general anasarca. Opium. In hydrothorax, or dropsy of the chest, without anasarca, paracentesis, or puncture in the side. "It is sometimes impossible even to relieve the dropsy of intemperance; and the dropsical from this cause can never expect again to enjoy the pleasures of existence in full measure." (Beddoes.)

Genus V. *Ascites.* Dropsy of the abdomen.

The swelling of the abdomen is tense, scarcely elastic, but fluctuating; the fluctuation can sometimes be perceived by spreading one hand on one side of the abdomen, and striking with the other hand on the opposite side. Ascites is attended with scarcity of urine, thirst, and after some time a degree of hectic fever.

Ascites most usually originates through the medium of a diseased liver; and such disease is, in the greater number of instances, itself induced by intemperance in spirituous liquors. Like the disease, however, of the lungs preceding dropsy in the chest, liver complaints productive of ascites, may be brought on by the precipitate application of cold succeeding to the extremes of heat, by indolence, mental affections, and other causes. Ascites sometimes originates from debility in the abdominal lymphatics, without the intervention of any hepatic disease.

M. M. Ascertain by enquiry into previous and present symptoms, whether any degree of liver complaint has preceded the dropsical accumulation; whether there is any disposition to jaundice of the skin; whether the alvine excretions are insufficient, whitish, and slimy; whether there has been any pain in the region of the liver, difficulty of lying on the side, especially on the left side, high colour of the urine, pain in the right shoulder, &c. and adapt the treatment accordingly. If the water is independant of disease in the liver, chrystals of tartar, digitalis, other diuretics, and steel, may be immediately had recourse to, without the intervention of calomel purgatives and of emetics, which last are almost always indicated in the more usual form of ascites, that form a morbid affection of the biliary organs. Emetics in hepatic ascites are often attended with most beneficial effects. "Per vomitus solvuntur cuncta tenacia, concutiuntur obstructa, expelluntur stagnantia, unde mirabiliter in hoc morbo prosunt." (Boerhaave.) In the administration of ascitic purgatives, care must be taken that, from the violence of excitement which they occasion, they do not induce peritoneal inflammation. A combination of gamboge, elaterium, and calomel, is frequently employed as a purgative in ascites. Mercurial ointment to the region of the liver. Tonics, especially steel. The inhalation of vital air, as recommended and employed by Dr. Thornton and others. Tapping. This is to be regarded in general as merely a palliative: if however there has not been any very considerable disease of the liver, or the debility is not extremely urgent, tapping may be advised with a prospect of effecting a radical cure, provided due care is at the same time employed to maintain a proper excitement, or, as it is generally expressed, to restore and preserve the tone of the system.

Genus V. *Hydrometria.* Dropsy of the womb.

This, like the physometra, already mentioned, often assumes a deceitful resemblance to pregnancy. It is characterized by dropsical swelling, confined to the region of the uterus, not being accompanied by other symptoms of dropsy.

It is a disease to which the unmarried and the barren are principally obnoxious; sometimes it follows abortion.

M. M. Stimulant fomentations. Drastic purgatives. Aromatic fœtid gums. Emmenagogues.

Genus VII. *Hydrocele.* Dropsy of the scrotum. See SURGERY.

SECT. IV. *Solidæ.* Swellings of solid parts.

Genus I. *Physconia.* A swelling chiefly occupying a portion of the abdomen, increasing gradually, and neither tense nor sonorous as in pneumatosis, nor fluctuating as in dropsy.

This disease is principally formed by a schirrous state of the several parts, and viscera, which form its seat. These schirrous enlargements are generally incurable.

Genus II. *Rachitis.* Rickets. See INFANCY.

ORDER III. *Impetigines.*

Deformities and discolourations of the external surface from general disease.

Genus I. *Scrophula.* King's evil.

Swellings of the lymphatic glands, terminating in ulcer, are perhaps the only proper characteristics of actual scrophula: the thick upper lip, transparent skin, and other appearances which are considered as symptoms of the disease, are merely marks of peculiar predisposition.

A scrophulous habit is merely a susceptibility of disease, arising from torpor in the lymphatic vessels, and when brought on by the agency of exciting causes, consists in a peculiar action of the lymphatic glands, by which inflammation and at length ulceration, with a discharge of grumous matter, are induced.

Its exciting causes are those which encourage the original debility, and the disease may almost certainly be avoided by attention to diet and regimen; by nutritious food, a pure oxygenous atmosphere, cleanliness, exercise, &c. See INFANCY.

When by neglect, the predisposition has been permitted to break out into disease, calomel purges, steel, small doses of digitalis, warm and sea-bathing, muriates and phosphates of barytes? above all cleanliness; ventilation, stimulating nutritious diet. Let the mind be preserved free from the erroneous idea, that to cure scrophula is to purge away gross humours. See SURGERY.

Genus II. *Syphilis.* Venereal disease.

After impure connection, a disorder of the genitals, ulcers in the mouth and nose. Eruptions on the skin of a copper colour, terminating in ulceration; these are principally situated near the margin of the hair; blotches on the surface of the body, especially on the surface of the face. Nocturnal pains in the centre of the bones.

M. M. Mercurials. Nitric acid. Tonics. N. B. For the local application to venereal ulcers, the more particular treatment of the complaint, and the mode of curing gonorrhea virulenta, see SURGERY.

Genus III. *Scorbutus,* scurvy.

Indolence and lassitude; gloomy and tumid countenance; gums livid, and disposed to bleed spontaneously, or from the slighest irritation; skin dry, and covered with livid spots; œdematous swellings of the ancles. Scurvy appears to originate from want of, or exhausted excitement, both in the venous and absorbent system; it is produced by a protracted course of salt food, and by mental depression.

M. M. Fresh animal and vegetable diet. Juice of lemon. Bark. Steel. Terrene atmosphere. Mental excitement.

The elephantiasis, lepra, frambæsia, and trichoma, forming the fourth, fifth, sixth, and seventh genera of this order, are diseases of such rare occurrence in this country, as not to require any particular description.

For the more common eruptions which require local application, see SURGERY.

Genus III. *Icterus,* jaundice.

Symptoms. Yellowness of the skin and eyes; white and slimy fæces; high-coloured urine, tinging linen yellow; langour, lassitude, and extreme depression of spirits.

The yellow colour of the skin, which constitutes jaundice, arises from the diffusion through the system of that bile, which, in the natural course, would pass through the biliary ducts into the intestinal canal. This impregnation of the system with bile has been supposed to be effected in three ways, viz. through the medium of the lacteal vessels and the thoracic duct, when the obstruction is in the duodenum; and by regurgitation through the hepatic veins, or absorption by the lymphatics of the liver, when the obstruction is in some part of the bile's course previous to its arrival in the duodenum.

This interruption of the biliary secretion may originate from a spasmodic affection near the duct; from chronic inflammations, or other diseases of the liver interfering with the secretion; from certain concretions lodging in some part of the hepatic organs, called gall-stones; and, as pointed out by Mr. Townsend, from viscid mucus stopping up or obstructing the biliary passages. Indeed, whatever hinders the bile from passing into the duodenum may prove a source of jaundice.

The first of the above species of jaundice is generally of a temporary nature; it occurs principally in those who have much irritability of habit, in consequence of violent passions, and other sources of spasmodic affections.

The second species is not of so decided a nature; it follows upon a long course of intemperance in spirituous liquors, and is only to be remedied by removing the disease of the liver itself.

The biliary calculi, which give rise to the third species of jaundice, appear, like urinary concretions, to arise from some defective action in the secretory or absorbing vessels of the parts in which they are formed or lodged; their production, like the stone in the bladder, is evidently favoured by a retention of fluid, from which they are formed. It may therefore be inferred, that gall-stones are never, or seldom, produced without some previous jaundice having taken place. Thus they are both the cause and consequence of the disease. Their presence may be ascertained from jaundice frequently disappearing and returning, from the appearance of biliary concretions among the fæces, and from the disease being attended with shooting pains in the epigastric region, and right hypochondrium. Nausea, difficult respiration, and sickness, often likewise accompany this species of jaundice.

The icterus mucosus of Townsend, which is perhaps the most frequent species of jaundice, is unattended either by pain or spasmodic affections; there are no gall-stones observed in the fæces; but these are generally discharged mixed with much slime and viscidities. It is generally accompanied with, and indeed is most commonly occasioned by, a depression of mind, especially when favoured by sedentary habits, breathing an impure atmosphere, living upon unwholesome innutritious diet, or indulging in the too free use of "spirituous potation."

While it is the most frequent, and oftentimes the most protracted, of any of the species of jaundice, it is at the same time most easy of cure when properly understood and managed.

M.M. Emetics. Calomel purgatives. Bitter. Tonics, especially colombo, with rhubarb. Pure air. Exercise on horse back. Mental excitement.

In icterus spasmodicus, opium, assafœtida, æther, electricity. If the spasm depends upon any irritations in the stomach or bowels, these to be removed by emetics, purgatives, anthelmintics. In icterus calculosus, emetics to facilitate the passage of the gall-stones. Antispasmodics. Warm bathing. Emollient clysters. Vegetable tonics, and steel.

N. B. The average doses of medicines will be found stated in the articles Materia Medica, and Pharmacy.

MEDIETAS LINGUÆ, a jury or inquest impanelled, whereof the one-half consists of natives or denizens, the other strangers; and used in pleas wherein the one party is a stranger, the other a denizen.

MEDIUM, in logic, the mean or middle term of a syllogism, being an argument, reason, or consideration, for which we affirm or deny any thing; or, it is the cause why the greater extreme is affirmed or denied of the less in the conclusion.

Medium, or Mean, *geometrical*. See Mean.

MEDULLA OBLONGATA. See Anatomy.

Medulla spinalis. See Anatomy.

MEDUSA, a genus of vermes of the order mollusca. The generic character is, body gelatinous, or bicular, and generally flat underneath: mouth central beneath. The animals of this genus consist of a tender gelatinous mass of different figures, furnished with arms or tentacular processes, proceeding from the lower surface: the larger species, when touched, cause a slight tingling and redness, and are usually denominated sea-nettles; they are supposed to constitute the chief food of cetaceous fish, and most of them shine with great splendour in the water. There are 44 species. See Plate Nat. Hist. fig. 262.

MEIONITI, a mineral found only among the lava of Vesuvius, always crystallized. Primitive form, a prism whose bases are squares. It occurs usually in eight-sided prisms, and terminated by four-sided pyramids. Sometimes the edges of the prism are truncated. Colour greyish-white; fracture flat; melts before the blowpipe into a white spongy glass.

MELAMPODIUM, a genus of the class and order syngenesia polygamia necessaria. The calyx is five-leaved; recept. chaffy, conical; down one-leaved, involuted, converging. There are three species, herbs of the West Indies.

MELANITE, a mineral found in the neighbourhood of Vesuvius, and formerly called black garnet. Its colour is black or brownish. Crystallized in six-sided prisms, terminated by trihedral summits. It is composed of

40	silica
28.5	alumina
16.5	oxide of iron
10.0	magnesia
3.5	lime
0.25	oxide of manganese.
98.75	

MELALEUCA, a genus of the polyandria order, belonging to the polyadelphia class of plants. The calyx is quinquepartite, superior; the corolla pentapetalous; the filaments are very numerous, and collected in such a manner as to form five pencils: there is one style; the capsule is half-covered with the calyx, formed like a berry, and is trivalved and trilocular. The species are 11, natives of India and the South Sea islands. The most remarkable species is the leucadendron, from a variety of which (the latifolia, or broad-leaved leucadendron) the cajeput oil is obtained; a medicine in very high esteem among the Eastern nations, particularly in India. It is said to be obtained by distillation from the fruit of the tree. When brought into this country it is a liquid of a greenish colour, of a fragrant but at the same time a very peculiar odour, and of a warm pungent taste. Some authors, however, represent this oil as being, when of the best quality, a white or colourless fluid; and it has been said by the authors of the Dispensatorium Brunsvicense, when prepared in Europe from the seeds sent from India, to be entirely of this appearance. Hitherto the oleum cajeput has been but little employed either in Britain or on the continent of Europe; but in India it is used both internally and externally, and is highly extolled for its medical properties. It is applied externally where a warm and peculiar stimulus is requisite; it is employed for restoring vigour after luxations and sprains, and for easing a violent pain in gouty and rheumatic cases, in tooth-ache, and similar affections; but it has been chiefly celebrated as taken internally, and it is particularly said to operate as a very powerful remedy against tympanic affections.

MELAMPYRUM, *cow-wheat*, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 40th order, personatæ. The calyx is quadrifid; the upper lip of the corolla is compressed, with the edges folded back; the capsule is bilocular and oblique, opening at one side; three are two gibbous seeds. There are five species, four of them natives of Britain, and growing spontaneously among corn-fields. They are exellent food for cattle; and Linnæus tells us, that where they abound, the yellowest and best butter is made. Their seeds, when mixed with bread, give it a dusky colour; and, according to some authors, produce a vertigo, and other disorders of the head; but this is denied by Mr. Withering, though he allows that they give it a bitter taste.

MELASTOMA, the *American gooseberry tree*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 17th order, calycanthemæ. The calyx is quinquefid and campanulated; the petals are five, inserted into the calyx; the berry is quinquelocular, and wrapped in the calyx. There are 67 spec. most of them shrubs of the warm parts of America, and very beautiful on account of the variegation of their leaves. Most of the leaves are of two different colours on their surfaces; the under side being either white, gold-coloured, or russet, and the upper parts of different shades of green; so that they make a fine appearance in the hot-house all the year round. There are but few of these plants in the European gardens; which may, perhaps, have been occasioned by the difficulty of bringing over growing plants from the West Indies; and the seeds, being small when taken out from the pulp of their fruits, rarely succeed. Some of these species strike very easily from cuttings.

MELCHITES, in church history, the name given to the Syriac, Egyptian, and other christians of the Levant. They celebrate mass in the Arabian language. The religious, among the Melchites, follow the rule of St. Basil, the common rule of all the Greek monks. They have four fine convents, distant about a day's journey from Damas, and never go out of the cloister.

MELCHIZEDECHIANS, in church history, a sect which arose about the beginning of the third century, and affirmed, that Melchisedech was not a man, but a heavenly power, superior to Jesus Christ.

MELEAGRIS, in ornithology, the turkey, a genus of birds belonging to the order of gallinæ. The head is covered with spongy caruncles; and there is likewise a membranaceous longitudinal caruncle on the throat. There are but two species, viz. the gallopavo, or North American turkey of Ray; and the satyra, or horned turkey. The first has a caruncle both on the head and throat; and the breast of the male is bearded or tufted. It lives upon grain and insects; when the cock struts, he blows up his breast, spreads and erects his feathers, relaxes the caruncle on the forehead, and the naked parts of the face and neck become intensely red. Barbot informs us that very few turkeys are to be met with in Guinea, and those only in the hands of the chiefs of the European forts; the negroes declining to breed any on account of their tenderness, which sufficiently proves them not to be natives of that climate. He also remarks, that neither the common poultry nor ducks are natural to Guinea, any more than the turkey. Neither is that bird a native of Asia; the first that were seen in Persia were brought from Venice by some Armenian merchants. They are bred in Ceylon, but not found wild. In fact, the turkey, properly so called, was unknown to the antient naturalists, and even to the old world, before the discovery of America; and with this the Portuguese name peru remarkably coincides. It was a bird peculiar to the new continent, and is now the commonest wild-fowl in the northern parts of that country, where they are frequently met with by hundreds in a flock; in the day-time they frequent the woods, where they feed on acorns, and return at night to the swamps to roost, which they do on the trees. They are frequently taken by means of dogs, though they run faster for a time; but the dogs persisting in the pursuit, the birds soon grow fatigued, and take to the highest trees, where they will suffer themselves to be shot one after another, if within reach of the marksman. This fowl was first seen in France in the reign of Francis I. and in England in that of Henry VIII. By the date of the reign of these monarchs, the first turkeys must have been brought from Mexico, the conquest of wh ch was completed A. D. 1521.

The turkey hen begins to lay early in the spring, and will often produce a great number of eggs, which are white, marked with reddish or yellow spots, or rather freckles. She sits well, and is careful of her young; of which in this climate she will often have from 14 to 17 for one brood: but she scarcely ever sits more than once in a season, except allured thereto by putting fresh eggs under her as soon as the first set are hatched; for, as she is a close sitter, she will willingly remain two months on the nest, though this conduct, as may be supposed, is said greatly to injure the bird. Turkeys are bred in quantities in some of the eastern counties of England, and are driven up to London towards autumn for sale in flocks of several hundreds, which are collected from the several cottages about Norfolk, Suffolk, and neighbouring counties, the inhabitants of which think it well worth their while to attend carefully to them, by making these birds a part of their family during the breeding-season. It is pleasing to see with what facility the drivers manage them by means of a bit of red rag fastened to the end of a stick, which, from their antipathy to it as a colour, acts with the same effect as a scourge to a quadruped.

Of the turkey there are several varieties, which have arisen from domestication. The most common is dark-grey, inclining to black, or barred dusky-white and black. There is also a beautiful variety of a fine deep copper colour, with the greater quills pure white, and the tail of a dirty white; it is when old a most beautiful bird. A variety with a pure white plumage is also now not unfrequent, and appears very beautiful. It was once esteemed as a great rarity, and the breed supposed originally to have arisen in Holland. The sahjou inhabits India, and is sometimes less than the last. See Plate Nat. Hist. fig. 261.

MELES, in zoology. See URSUS.

MELIA, *azaderach*, or the *bead-tree*, a genus of the monogynia order, in the decandria class of plants, and in the natural method ranking under the 23d order, trihilatæ. The calyx is quinquedentated; the petals five; the nectarium cylindrical, as long as the corolla, with its mouth ten-toothed; the fruit is a plum with a quinquelocular kernel. There are three species, all of them exotic trees of the Indies, rising near 20 feet high, adorned with large pinnated or winged leaves, and clusters of pentapetalous flowers. They are all propagated by seeds sown on hotbeds.

MELIANTHUS, *honey-flower*, a genus of the angiospermia order, in the didynamia class of plants, and in the natural method ranking under the 24th order, corydales. The calyx is pentaphyllous, with the lowermost leaf gibbous: there are four petals, with the nectarium under the lowest ones. The capsule is quadrilocular. There are three species: 1. The major has many upright, ligneous, durable stalks, and from the sides and tops of the stalks long spikes of chocolate-coloured flowers. 2. The minor has upright, ligneous, soft, durable stalks; and from the sides and ends of the branches long, loose, pendulous bunches of flowers tinged with green, saffron-colour, and red. Both the species flower about June; but rarely produce seeds in this country. They are very ornamental, both in foliage and flower, and merit admittance in every collection. They are easily propagated by suckers and cuttings. They thrive best in a dry soil, and in a sheltered warm exposure. 3. The commdous, little known.

MELICA, *ropegrass*, a genus of the digynia order, in the triandria class of plants, and in the natural method ranking under the 4th order, gramina. The calyx is bivalved, biflorous, with an embryo of a flower betwixt the two florets. There are three species, of which the most remarkable is the nutans. It is a native of several parts of Britain, and the adjacent islands; and the inhabitants of some of the western islands make ropes of it for fishing-nets, as it will bear the water for a long time without rotting.

MELICOCCA, a genus of the class and order octandria monogynia. The calyx is four-parted; the petals four, bent back; stigma subpeltate, drupe coriaceous. There is one species, a tree of South America.

MELICYTUS, a genus of the class and order dioecia pentandria. There is one species, of New Zealand, little known.

MELISSA, *baum*, a genus of the didynamia gymnospermia class of plants, with a monopetalous ringent flower, the lower lip of which is divided into three segments, whereof the middle one is cordated: the seeds are four in number, and contained in the bottom of the cup. There are six species.

Baum is greatly esteemed among the common people as good in disorders of the head and stomach; but is less regarded in the shops. It is most conveniently taken in infusion by way of tea; the green herb is greatly better than the dry, which is contrary to the general rule in relation to other plants.

MELITTIS, bastard baum, a genus of the didynamia gymnospermia class of plants; the upper lip of whose cup is emarginated; the upper lip of its flower is plane, and the lower one crenated. There are two species.

MELIUS INQUIRENDUM, in law, a writ that lies for a second inquiry to be made of what lands, &c. a man died seized; when partiality is suspected upon the writ diem clausit, &c.

MELLATS. This genus of salts is but imperfectly known, in consequence of the scarcity of mellitic acid. Hitherto they have been examined only by Klaproth and Vauquelin, and even by them too slightly to admit a description of their properties. The following are all the facts hitherto ascertained.

1. When mellitic acid is neutralized by potass, the solution crystallizes in long prisms. The acid appears capable of combining with this salt, and forming a supermellat of potass. For when the mellite (or native mellat of alumina) is decomposed by carbonat of potass, and the alkaline solutions mixed with nitric acid, crystals are obtained consisting of mellitic acid combined with a small portion of potass.

2. When mellitic acid is neutralized by soda, the solution crystallizes in cubes or three-sided tables; sometimes insulated, sometimes in groups.

3. When mellitic acid is saturated by ammonia, the solution yields fine transparent six-sided crystals, which become opaque when exposed to the air, and assume the white colour of silver.

4. When mellitic acid is dropt into barytes water, strontian water, or lime water, a white powder immediately precipitates, which is dissolved by adding a little more of the acid.

5. When the acid is mixed with a solution of sulphat of lime, very small gritty crystals precipitate, which do not destroy the transparency of the water; but the addition of a little ammonia renders the precipitate flaky. The precipitate produced by this acid in lime water is redissolved by the addition of nitric acid.

6. When this acid is dropt into acetat of barytes, a flaky precipitate appears, which is dissolved by adding more acid. With muriat of barytes it produces no precipitate; but in a short time a group of transparent needle-form crystals is deposited, consisting most likely of supermellat of barytes.

7. When this acid is dropt into sulphat of alumina, it throws down an abundant precipitate in the form of a white flaky powder.

MELLITE, *honeystone, mellat of alumina.* This mineral was first observed about 10 years ago in Thuringia, between the layers of wood coal. It is of a honey-yellow colour (whence its name); and is usually crystallized in small octahedrons, whose angles are often truncated. Fracture conchoidal. Specific gravity, according to Abich, 1.666. When heated it whitens, and in the open air burns without being sensibly charred. A white matter remains, which effervesces slightly with acids, and which at first has no taste, but at length leaves an acid impression upon the tongue.

Klaproth analysed the mellite in 1799, and ascertained it to be a compound of alumina and a peculiar acid, to which he gave the name of mellitic. And this analysis was soon after confirmed by M. Vauquelin.

MELLITIC ACID has been found only in the mellite. It may be procured from that mineral by the following process: Reduce the mellite to powder, and boil it in about 72 times its weight of water. The acid combines with the water, and the alumina separates in flakes. By filtring the solution, and evaporating sufficiently, the mellitic acid is obtained in the state of crystals.

These crystals are either very fine needles, sometimes collected into globules, or small short prisms. They have a brownish colour, and a taste at first sweetish-sour, and afterwards bitterish.

This acid is not very soluble in water; but the precise degree of solubility has not been ascertained. When exposed to heat, it is readily decomposed, exhaling an abundant smoke, which however is destitute of smell. A small quantity of insipid ashes remains behind, which do not alter the colour of litmus paper.

All attempts to convert it into oxalic acid by the action of nitric acid have failed. The nitric acid merely caused it to assume a straw-yellow colour.

The effect of the simple bodies on this acid has not been tried. It combines with alkalies, earths, and metallic oxides, and forms with them salts which are distinguished by the name of mellats. The properties of these compounds will be considered afterwards.

From the analysis of M. Klaproth, we learn that the mellite is composed of

46	mellitic acid
16	alumina
38	water
100.	

From other analyses by the same chemist, he infers that mellitic acid is composed of carbon, hydrogen, and oxygen, but the proportions are not yet known.

MELOCHIA, *Jew's mallow*, a genus of the pentandria order, in the monadelphia class of plants, and in the natural method ranking under the 37th order, columniferæ. The capsule is quinquelocular and monospermous. There are 11 species: but the only remarkable one is the olitorius, or common Jew's-mallow, which is a native of the warm parts of Asia and America. It is an annual plant. The flowers sit close on the opposite side of the branches to the leaves, coming out singly; they are composed of five small yellow petals, and a great number of stamina surrounding the oblong germen, which is situated in the centre of the flower, and afterwards turns to a rough swelling capsule two inches long, ending in a point, and having four cells filled with angular greenish seeds. This species is cultivated about the city of Aleppo in Syria, and in the East Indies, as a pot-herb; the Jews boiling the leaves, and eating them with their meat.

MELODINUS, a genus of the class and order pentandria digynia. It is contorted; nect. in the middle of the tube, stellate; berry two-celled, many-seeded. There is one species, a shrub of New Caledonia.

MELODY, in music, the agreeable effect of different sounds, ranged and disposed in succession; so that melody is the effect of a single voice or instrument, by which it is distinguished from harmony.

MELOE, a genus of insects of the order coleoptera; the generic character is; antennæ moniliform, with the last joint ovate; thorax roundish; wing-sheaths soft, flexile; head inflected. Among the principal species of meloe may be numbered the meloe proscarabæus, commonly called the oil-beetle. It is of considerable size, often measuring near an inch and a half in length; its colour is violet-black, especially on the antennæ and limbs; the wing-sheaths are very short, in the female insect especially, scarcely covering more than a third of the body, and are of an oval shape. This species is frequent in the advanced state of spring in fields and pastures, creeping slowly, the body appearing so swoln or distended with eggs as to cause the insect to move with difficulty. On being handled it suddenly exsudes from the joints of its legs, as well as from some parts of the body, several small drops of a clear, deep-yellow oil or fluid, of a very peculiar and penetrating smell. This oil or fluid has been highly celebrated for its supposed efficacy in rheumatic pains, &c. when used as an embrocation on the parts affected; for this purpose also the oil expressed from the whole insect has been used with equal success. The female of this species deposits her eggs, which are very small, and of an orange-colour, in a large heap or mass beneath the surface of the ground; each egg, when viewed by the microscope, appears of a cylindric shape, with rounded ends; from these are hatched the larvæ, which, at their first appearance, scarcely measure a line in length, and are of an ochre-yellow, with black eyes; they are furnished with short antennæ, six legs of moderate length, and a long, jointed, tapering body, terminated by two forked filaments or processes. These larvæ are found to live by attaching themselves to other insects, and absorbing their juices. They are sometimes seen strongly fastened to common flies, &c. a practice so extraordinary as to have caused considerable doubt whether they could possibly have been the real larvæ of the meloe proscarabæus. The accurate observations of Degeer, however, have completely proved that fact.

The meloe scabrosus extremely resembles the preceding, and is found in similar situations, but differs in being of a reddish purple colour, with a cast of deep gilded green.

Meloe vesicatorius, blister-fly or Spanish fly, is an insect of great beauty, being entirely of the richest gilded grass-green, with black antennæ. Its shape is lengthened, and the abdomen, which is pointed, extends somewhat beyond the wing-sheaths; its usual length is about an inch. This celebrated insect, the cantharis of the materia medica, forms, as is well known, the safest and most efficacious epispastic, or blister-plaster; raising, after the space of a few hours, the cuticle, and causing a plentiful serous discharge from the skin. It is supposed however that the cantharis of Dioscorides, or that used by the antients for the same purpose, was a different species, viz. the meloe cichorei of Linnæus, an insect nearly equal in size to the meloe proscarabæus, and of a black colour, with three transverse yellow bands on the wing-shells. The meloe vesicatorius is principally found in the warmer parts of Europe, as Spain, the south of France, &c. It is also observed, though far less plentifully, in some parts of our own country. See Plate Nat. Hist. fig. 263.

MELON. See CUCUMIS.

MELOTHRIA, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the 34th order, cucurbitaceæ. The calyx is quinquefid; the corolla campanulated and monopetalous; the berry trilocular and monospermous. There is only one species, viz. the pendula, a native of Carolina, Virginia, and also many of the American islands. The plants strike out roots at every joint, which fasten themselves into the ground, by which means their stalks extend to a great distance each way. The flowers are very small, in shape like those of the melon, of a pale sulphur-colour. The fruit in the West Indies grows to the size of a pea, is of an oval figure, and changes to black when ripe; these are by the inhabitants sometimes pickled when they are green. In Britain the fruit are much smaller, and are so hidden by the leaves that it is difficult to find them. The plants are too tender to be reared in this country without artificial heat.

MELYRIS, a genus of insects of the order coleoptera: the generic character is, antennæ entirely perfoliate; head inflected under the thorax; thorax margined; lip elevate, emarginate; jaw one-toothed, pointed. There are three species. See Plate Nat. Hist. fig. 264.

MEMBRANE. See ANATOMY.

MEMECYLON, a genus of the octandria monogynia class and order. The calyx is superior; corolla one-petalled; anth. inserted in the side of the apex of the filament; berry crowned with cylindrical calyx. There are three species, trees of the East Indies.

MEMORY, *artificial*, a method of assisting the memory, by forming certain words, the letters of which shall signify the date or æra to be remembered. In order to this, the following series of vowels, diphthongs, and consonants, together with their corresponding numbers, must be exactly learned, so as to be able at pleasure to form a technical word, that shall stand for any number, or to resolve such a word already formed.

a	*e*	*i*	*o*	*u*	*au*	*oi*	*ei*	*ou*	*y*
1	2	3	4	5	6	7	8	9	0
b	*d*	*t*	*f*	*l*	*s*	*p*	*k*	*n*	*z*

The first five vowels, in order, naturally represent 1, 2, 3, 4, 5; the diphthong *au* = 6, as being composed of *a* and *u*, or 1 + 5 = 6; and for the like reason, *oi* = 7, and *ou* = 9. The diphthong *ei* will easily be remembered for 8, as being the initials of the word. In like manner, where the initial consonants could conveniently be retained, they are made use of to signify the number, as *t* for 3, *f* for 4, *s* for 6, and *n* for 9. The rest were assigned without any particular reason, unless that possibly *p* may be more easily remembered for 7 or septem, *k* for 8, or ὀκτω, *d* for 2, or duo; *b* for 1, as being the first consonant; and *l* for 5, being the Roman letter for 50; than any others that could have been put in their places.

It is farther to be observed, that *z* and *y* being made use of to represent the cypher, where many cyphers meet together, as 1000, 1000000, &c. instead of a repetition of *a z y z y z y*, &c. let *g* stand for 100, *th* for a thousand, and *m* for a million. Thus *ag* will be 100, *ig* 300; *oug* 900, &c. *ath* 1000, *am* 1000000, *loum* 59000000, &c.

Fractions may be set down in the following manner: let *r* signify the line separating the numerator and denominator, the first coming before, the other after it; as *iro* $\frac{3}{4}$, *urp* $\frac{5}{7}$, *pourag* $\frac{79}{100}$, &c. When the numerator is 1, or unit, it need not be expressed, but begin the fraction with *r*; as *re* $\frac{1}{2}$, *ri* $\frac{1}{3}$, *ro* $\frac{1}{4}$, &c. So in decimals, *rag* $\frac{1}{100}$, *rath* $\frac{1}{1000}$.

This is the principal part of the method; which consists in expressing numbers by artificial words. The application to history and chronology is also performed by artificial words. The art herein consists in making such a change in the ending of the name of a place, person, planet, coin, &c. without altering the beginning of it, as shall readily suggest the thing sought, at the same time that the beginning of the word being preserved, shall be a leading or prompting syllable to the ending of it, so changed. Thus, in order to remember the years in which Cyrus, Alexander, and Julius Cæsar, founded their respective monarchies, the following words may be formed; for Cyrus, Cyr*uts*; for Alexander, Alex-

ita; for Julius Cæsar, Jul*ios*. *Uts* signifies, according to the powers assigned to the letters before-mentioned 536; *ita* is 331; and *os* is 46. Hence it will be easy to remember, that the empire of Cyrus was founded 536 years before Christ, that of Alexander 331, and that of Julius Cæsar 46. This account is taken from a treatise, entitled, a New Method of Artificial Memory; where the reader will find several examples in chronology, geography, &c. of such artificial words disposed in verses, which must be allowed to contribute much to the assistance of the memory, since being once learned, they are seldom or never forgotten. However, the author advises his reader to form the words and verses himself, in the manner described above, as he will probably remember these better than those formed by another.

We shall, in this place, give his table of the kings of England since the Conquest, where one thousand being added to the Italics in each word, expresses the year when they began their reigns. Thus,

Will con*sau*, Ruf*koi*, Hen*rag*
Steph*bil* & Hensec*buf*, Rich*bein*, J*ann*, Heth*das* & Ed*doid*.
Ed*setyp*, Edter*tep*, Rise*tois*, Hefo*toun*, Hen*sad*que.
Hen*fifed*, Edquar*fauz*, Efi-Ro*kt*, Hensep*feil*, Henoc*lyh*.
Edsex*los*, Mary*lut*, Els*luk*, Jam*syd*, Caroprim*sel*.
Carsee*sok*, Jam*seif*, Wil*seik*, An*pyd*, Geo*bo-doi*.

MENACHANITE. This substance has been found abundantly in the valley of Menachan in Cornwall; and hence was called menachanite by Mr. Gregor, the discoverer of it. It is in small grains like gunpowder, of no determinate shape, and mixed with a fine grey sand. Colour black. Easily pulverised. Powder attracted by the magnet. Specific gravity 4.427. Does not detonate with nitre. With two parts of fixed alkali it melts into an olive-coloured mass, from which nitric acid precipitates a white powder. The mineral acids only extract from it a little iron. Diluted sulphuric acid, mixed with the powder, in such a proportion that the mass is not too liquid, and then evaporated to dryness, produces a blue-coloured mass. Before the blowpipe does not decrepitate nor melt. It tinges microcosmic salt green; but the colour becomes brown on cooling; yet microcosmic salt does not dissolve it. Soluble in borax, and alters its colour in the same manner.

According to the analysis of Mr. Gregor, it is composed of

46 oxide of iron
45 oxide of titanium
———
91, with some silica and manganese.

According to M. Klaproth's analysis, it is composed of 51.00 oxide of iron
45.25 oxide of titanium
3.50 silica
.25 oxide of manganese.
———
100.00

Another variety of this ore from the Uralian mountains, analysed by Lowitz, contained
53 oxide of titanium
47 oxide of iron
———
100.

A mineral, nearly of the same nature with the one just described, has been found in Bavaria. Its specific gravity is only 3.7. According to the analysis of Vauquelin and Hecht, it is composed of

49 oxide of titanium
35 iron
2 manganese
14 oxygen combined with the iron and manganese
———
100.

A specimen of the same ore from Botany Bay has been lately analysed by Mr. Chenevix.

MENAIS, a genus of the pentandria monogynia class and order. The calyx is three-leaved; the corolla salver-shaped; berry four-celled; seeds solitary. There is one species, a herb of South America.

MENDICANTS, or begging friars, several orders of religious in popish countries, who, having no settled revenue, are supported by the charitable contributions they receive from others.

MENISCIUM, a genus of the cryptogamia filices. The capsules are heaped in crescents interposed between the veins of the pod. There is one species, a native of the West Indies.

MENISCUS. See Optics.

MENISPERMUM, a genus of the dioecia dodecandria class and order. The male petals are four outer, eight inner; stamina sixteen; female corolla, as in the male; stam. eight, barren; berries two, one-seeded. There are 13 species, herbs of the East Indies.

MENNONITES, a sect of baptists in Holland, so called from Mennon Simonis of Friezland, who lived in the sixteenth century. This sect believe that the New Testament is the only rule of faith; that the terms person and trinity are not to be used in speaking of the Father, Son, and Holy Ghost; that the first man was not created perfect; that it is unlawful to swear or to wage war upon any occasion; that infants are not the proper subjects of baptism; and that ministers of the gospel ought to receive no salary. They all unite in pleading for toleration in religion, and debar none from their assemblies who lead pious lives, and own the scriptures for the word of God.

MENSES. See Physiology.

MENSTRUUM, in chemistry, the fluid in which a solid body is dissolved. Thus water is a menstruum for salts, and gums; and alcohol for resins.

MENTHA, mint, a genus of the gymnospermia order, in the didynamia class of plants; and in the natural method ranking under the 42d order, verticillatæ. The corolla is nearly equal and quadrifid, with one segment broader than the rest, and emarginated; the stamina are erect, standing asunder. There are 19 species; but not more than three are cultivated for use, namely, the viridis, or common spearmint, the piperita or peppermint, and the pulegium or pennyroyal. All these are so well known as to need no description; and all of them are very easily propagated by cuttings, parting the roots, or by offsets.

For culinary purposes, the spearmint is preferred to the other two; but for medicine, the peppermint and pennyroyal have almost entirely superseded it. A conserve of the leaves is very grateful; and the distilled waters both simple and spirituous, are universally thought pleasant. Dr. Lewis says, that dry mint digested in rectified spirits of wine, gives out a tincture which appears by day-light of a fine dark-green, but by candle-light of a bright red colour. The fact is, that a small quantity of this tincture is green either by day-light or by candle-light, but a large quantity of it seems impervious to common day-light; however, when held betwixt the eye and a candle, or betwixt the eye and the sun, it appears red.

The virtues of mint are those of a warm stomachic, capable of relieving colicky pains, and the gripes, to which children are subject. It likewise proves an useful cordial in languors and faintness. When prepared with rectified spirit, the whole virtues of the mint are extracted. The expressed juice contains only the astringent and bitter parts, together with the mucilaginous substance common to all vegetables. The peppermint is much more pungent than the others.

Pennyroyal has the same general characters with the mint, but is more acrid and less agreeable when taken into the stomach. It was long held in great esteem in hysteric complaints, and suppressions of the menses, but its effects are trifling. It is observable, that both water and rectified spirit extract the virtues of this herb by infusion, and likewise elevate the greatest part of them by distillation.

MENTZELIA, a genus of the polyandria monogynia class and order. The cal. is five-leaved; cor. five-petalled; caps. inferior, cylindric, many-seeded. There is one species, an annual of South America.

MENYANTHUS, buckbean, a genus of the pentandria monogynia class of plants, with a monopetalous funnel-like flower, divided into five deep segments at the limb: the fruit is an oval capsule with one cell, containing a great many small seeds. There are five species.

Buckbean, called by authors trifolium palustre and paludosum, is greatly recommended as a diuretic in dropsical cases; as also in the cure of intermittent fevers, and disorders of the breast arising from tough matter in the lungs: the general way of taking it is in a strong infusion, though many prefer the juice fresh expressed from the leaves.

MERCATOR's *projection of maps*. See Map.

MENSURATION, in general, denotes the act or art of measuring lines, superficies and solids; and it is, next to arithmetic, a subject of the greatest use and importance, both in affairs that are absolutely necessary in human life, and in every branch of mathematics; a subject by which sciences are established, and commerce is conducted; by whose aid we manage our business, and inform ourselves of the wonderful operations in nature; by which we measure the heavens and the earth, estimate the capacities of all vessels and the bulks of all bodies, gauge our liquors, build edifices, measure our lands and the works of artificers, buy and sell an infinite variety of things necessary in life, and are supplied with the means of making the calculations which are necessary for the construction of almost all machines.

It is evident that the close connection of this subject with the affairs of men would very early evince its importance to them; and accordingly the greatest among them have paid the utmost attention to it; and the chief and most essential discoveries in geometry in all ages have been made in consequence of their efforts in this subject. Socrates thought that the prime use of geometry was to measure the ground, and indeed this business gave name to the subject; and most of the antients seem to have had no other end besides mensuration in view in all their geometrical disquisitions. Euclid's Elements are almost entirely devoted to it; and although there are contained in them many properties of geometrical figures, which may be applied to other purposes, and indeed of which the moderns have made the most material uses in various disquisitions of exceedingly different kinds; notwithstanding this, Euclid himself seems to have adapted them entirely to this purpose: for, if it is considered that his Elements contain a continued chain of reasoning, and of truths, of which the former are successively applied to the discovery of the latter, one proposition depending on another, and the succeeding propositions still approximating towards some particular object near the end of each book; and when at the last we find that object to be the quality, proportion, or relation between the magnitudes of figures both plane and solid; it is scarcely possible to avoid allowing this to have been Euclid's grand object: Accordingly he determined the chief properties in the mensuration of rectilineal plane and solid figures; and squared all such planes, and cubed all such solids. The only curve figures which he attempted besides are the circle and sphere; and when he could not accurately determine their measures, he gave an excellent method of approximating to them, by shewing how in a circle to inscribe a regular polygon which should not touch another circle, concentric with the former, although their circumferences should be ever so near together; and, in like manner, between any two concentric spheres to describe a polyhedron which should not any where touch the inner one: and approximations to their measures are all that have hitherto been given. But although he could not square the circle, nor cube the sphere, he determined the proportion of one circle to another, and of one sphere to another, as well as the proportions of all rectilineal similar figures to one another.

Archimedes took up mensuration where Euclid left it, and carried it a great length. He was the first who squared a curvilineal space, unless Hippocrates must be excepted on account of his lunes. In his times the conic sections were admitted in geometry, and he applied himself closely to the measuring of them as well as other figures. Accordingly he determined the relations of spheres, spheroids, and conoids, to cylinders and cones; and the relations of parabolas to rectilineal planes whose quadratures had long before been determined by Euclid. He has left us also his attempts upon the circle: he proved that a circle is equal to a right-angled triangle, whose base is equal to the circumference, and its altitude equal to the radius; and consequently that its area is found by drawing the radius into half the circumference; and so reduced the quadrature of the circle to the determination of the ratio of the diameter to the circumference; but which, however, has not yet been found. Being disappointed of the exact quadrature of the circle, for want of the rectification of its circumference, which all his methods would not effect, he proceeded to assign an useful approximation to it: this he effected by the numerical calculation of the perimeters of the inscribed and circumscribed polygons; from which calculations it appears that the perimeter of the circumscribed regular polygon of 192 sides is to the diameter, in a less ratio than that of $3\frac{1}{7}$ $(3\frac{10}{70})$ to 1, and that the inscribed polygon of 96 sides is to the diameter in a greater ratio than that of $3\frac{10}{71}$ to 1; and consequently much more than the circumference of the circle is to the diameter in a less ratio than that of $3\frac{1}{7}$ to 1, but greater than that of $3\frac{10}{71}$ to 1: the first ratio of $3\frac{1}{7}$ to 1, reduced to whole numbers, gives that of 22 to 7, for $3\frac{1}{7} : 1 :: 22 : 7$, which therefore will be nearly the ratio of the circumference to the diameter. From this ratio of the circumference to the diameter he computed the approximate area of the circle, and found it to be to the square of the diameter as 11 to 14. He likewise determined the relation between the circle and ellipse, with that of their similar parts. The hyperbola too, in all probability, he attempted; but it is not to be hoped, that he met with any success, since approximations to its area are all that can be given by all the methods that have since been invented.

Besides these figures, he has left us a treatise on the spiral described by a point moving uniformly along a right line, which at the same time moves with an uniform angular motion; and determined the proportion of its area to that of its circumscribed circle, as also the proportion of their sectors.

Throughout the whole works of this great man, which are chiefly on mensuration, he every where discovers the deepest design, and finest invention; and seems to have been (with Euclid) exceedingly careful of admitting into his demonstrations nothing but principles perfectly geometrical and unexceptionable: and although his most general method of demonstrating the relations of curved figures to straight ones, is by inscribing polygons in them, yet to determine those relations, he does not increase the number and diminish the magnitude of the sides ad infinitum; but from this plain fundamental principle, allowed in Euclid's Elements, viz. that any quantity may be so often multiplied, or added to itself, as that the result shall exceed any proposed finite quantity of the same kind, he proves that to deny his figures to have the proposed relations, would involve an absurdity.

He demonstrated also many properties, particularly in the parabola, by means of certain numerical progressions, whose terms are similar to the inscribed figures; but without considering such series to be continued ad infinitum, and then summing up the terms of such infinite series.

He had another very curious and singular contrivance for determining the measures of figures, in which he proceeds as it were mechanically by weighing them.

Several other eminent men among the ancients wrote upon this subject, both before and after Euclid and Archimedes; but their attempts were usually upon particular parts of it, and according to methods not essentially different from theirs. Among these are to be reckoned Thales, Anaxagoras, Pythagoras, Bryson, Antiphon, Hippocrates of Chios, Plato, Apollonius, Philo, and Ptolemy; most of whom wrote of the quadrature of the circle: and those after Archimedes, by his method, usually extended the approximation to a greater degree of accuracy.

Many of the moderns have also prosecuted the same problem of the quadrature of the circle, after the same methods, to greater lengths: such are Vieta and Metius, whose proportion between the diameter and circumference is that of 113 to 355, which is within about $\frac{3}{10000000}$ of the true ratio; but above all Ludolph van Ceulen, who, with an amazing degree of industry and patience, by the same ratio to 20 places of figures, making it that of 1 to 3.14159265358979323846 +. See CIRCLE.

Hence it appears, that all or most of the material improvements or inventions in the principles or methods of treating of geometry, have been made especially for the improvement of this chief part of it, mensuration, which abundantly shews the dignity of the subject; a subject which, as Dr. Barrow says, after mentioning some other things, "deserves to be more curiously weighed, because from hence a name is imposed upon that mother and mistress of the rest of the mathematical sciences, which is employed about magnitudes, and which is wont to be called geometry (a word taken from ancient use, because it was first applied only to measuring the earth, and fixing the limits of possessions): though the name seemed very ridiculous to Plato, who substitutes in its place the more extensive name of metrics or mensuration; and others after him give it the title of pantometry, because it teaches the method of measuring all kinds of magnitudes." See HEIGHTS, SURVEYING, LEVELLING, GEOMETRY, and GAUGING.

MERCURIALIS, mercury, a genus of the enneandria order, in the diœcia class of plants, and in the natural method ranking under the 38th order, tricoccæ. The calyx of the male is tripartite; there is no corolla, but 9 or 12 stamina; the antheræ globular and twin. The female calyx is tripartite; there is no corolla, but two styles; the capsule is bicoccous, bilocular, and monospermous. There are six species.

Of these, the perennis, according to Mr. Lightfoot, is of a soporific deleterious nature, noxious both to man and beast. There are instances of those who have eaten it by mistake, instead of the chenopodium bonus Henricus, or English mercury, and have thereby slept their last. Tournefort informs us, that the French make a syrup of the juice of the annua, another species, two ounces of which are given as a purge; and that they use it in pessaries and clysters, mixing one part of honey to one and a half of the juice. Dr. Withering differs greatly from Lightfoot concerning the qualities of the perennis. "This plant, (says he), dressed like spinach, is very good eating early in the spring, and is frequently gathered for that purpose; but it is said to be hurtful to sheep." Mr. Ray relates the case of a man, his wife, and three children, who experienced highly deleterious effects from eating it fried with bacon; but this was probably when the spring was more advanced, and the plant had become acrimonious. When steeped in water, it affords a fine deep-blue colour. Sheep and goats eat it; but cows and horses refuse it.

MERCURY, called also QUICKSILVER, was known in the remotest ages, and seems to have been employed by the antients in gilding and in separating gold from other bodies, just as it is by the moderns.

Its colour is white, and similar to that of silver; hence the names hydrargyrus, argentum vivum, quicksilver, by which it has been known in all ages. It has no taste nor smell. It possesses a good deal of brilliancy; and when its surface is not tarnished, makes a very good mirror. Its specific gravity is 13.568. At the common temperature of the atmosphere, it is always in a state of fluidity. In this respect it differs from all other metals. But it becomes solid when exposed to a sufficient degree of cold. The temperature necessary for freezing this metal is —39°, as was ascertained by the experiments of Mr. Macnab at Hudson's-bay. The congelation of mercury was accidentally discovered by the Petersburgh academicians in 1759. Taking the advantage of a very severe frost, they plunged a thermometer into a mixture of snow and salt, in order to ascertain the degree of cold. Observing the mercury stationary, even after it was removed from the mixture, they broke the bulb of the thermometer, and found the metal frozen into a solid mass. This experiment has been repeated very often since, especially in Britain. Mercury contracts considerably at the instant of freezing; a circumstance which misled the philosophers who first witnessed its congelation. The mercury in their thermometers sunk so much before it froze, that they thought the cold to which it had been exposed, much greater than it really was. It was in consequence of the rules laid down by Mr. Cavendish, that Mr. Macnab was enabled to ascertain the real freezing point of the metal.

Solid mercury may be subjected to the blows of a hammer, and may be extended without breaking. It is therefore malleable; but neither the degree of its malleability, nor its ductility, nor its tenacity, has been ascertained.

Mercury boils when heated to 660°. It may therefore be totally evaporated, or distilled from one vessel into another. It is by distillation that mercury is purified from various metallic bodies, with which it is often contaminated. The vapour of mercury is invisible and elastic like common air; like air, too, its elasticity is indefinitely increased by heat, so that it breaks through the strongest vessel. Geoffroy, at the desire of an alchymist, inclosed a quantity of it in an iron globe, strongly secured by iron hoops, and put the apparatus into a furnace. Soon after the globe became red-hot, it burst with all the violence of a bomb, and the whole of the mercury was dissipated.

Mercury is not altered by being kept under water. When exposed to the air, its surface is gradually tarnished, and covered with a black powder, owing to its combining with the oxygen of the atmosphere. But this change goes on very slowly, unless the mercury is either heated or agitated, by shaking it, for instance, in a large bottle full of air. By either of these processes, the metal is converted into an oxide: by the last, into a black-coloured oxide; and by the first, into a red-coloured oxide. This metal does not seem to be capable of combustion.

The oxides of mercury at present known are four in number:

1. The protoxide was first described with accuracy by Boerhaave. He formed it by putting a little mercury into a bottle, and tying it to the spoke of a mill-wheel. By the constant agitation which it thus underwent, it was converted into a black powder, to which he gave the name of *ethiops per se*. This oxide is readily formed by agitating impure mercury in a phial. It is a black powder without any of the metallic lustre, has no taste, and is insoluble in water. According to the experiments of Fourcroy, it is composed of 96 parts of mercury and 4 of oxygen. When this oxide is exposed to a strong heat, oxygen gas is emitted, and the mercury reduced to the metallic state. In a more moderate heat it combines with an additional dose of oxygen, and assumes a red colour.

2. When mercury is dissolved in nitric acid without the assistance of heat, and the acid is made to take up as much mercury as possible, it has been demonstrated, by the experiments of Mr. Chenevix, that it combines in that case with 10.7 per cent. of oxygen. Of course an oxide is formed, composed of 89.3 mercury and 10.7 oxygen. This is the deutoxide of mercury. This oxide cannot be separated completely from the acid which holds it in solution without undergoing a change in its composition; of course we are at present ignorant of its colour and other properties. Indeed it is very probable that it is the same with the black oxide just described under the name of protoxide; but this has not yet been proved in a satisfactory manner.

3. When mercury, or its protoxide, is exposed to a heat of about 600°, it combines with additional oxygen, assumes a red colour, and is converted into an oxide, which, in the present state of our knowledge, we must consider as a tritoxide. This oxide may be formed two different ways: 1. By putting a little mercury into a flat-bottomed glass bottle or matrass, the neck of which is drawn out into a very narrow tube, putting the mattrass into a sand-bath, and keeping it constantly at the boiling point. The height of the mattrass, and the smallness of its mouth, prevent the mercury from making its escape, while it affords free access to the air. The surface of the mercury becomes gradually black, and then red, by combining with the oxygen of the air: and at the end of several months the whole is converted into a red powder, or rather into small crystals, of a very deep red colour. The oxide, when thus obtained, was formerly called precipitate per se. 2. When mercury is dissolved, in nitric acid, evaporated to dryness, and then exposed to a pretty strong heat in a porcelain cup, it assumes, when triturated, a brilliant red colour. The powder thus obtained was formerly called red precipitate, and possesses exactly the properties of the oxide obtained by the former process.

This oxide has an acrid and disagreeable taste, possessing poisonous qualities, and acts as an escharotic when applied to any part of the skin. It is somewhat soluble in water. When triturated with mercury it gives out part of its oxygen, and the whole mixture is converted into protoxide or black oxide of mercury. When heated along with zinc, or tin filings, it sets these metals on fire. According to Fourcroy, it is composed of 92 parts of mercury and 8 of oxygen. But the analysis of Mr. Chenevix, to be described hereafter, gives, for the proportion of its component parts, 85 parts of mercury and 15 parts of oxygen.

The red oxide of mercury, prepared in the usual way, is not pure, but always contains a portion of nitric acid. If we dissolve it in muriatic acid, and precipitate it again, it falls in the state of a white powder, and retains a portion of muriatic acid. It was in this state that it was examined by Chenevix. The difficulty of procuring this oxide in a state of purity, and the uncertainty respecting the proportion of acid which it retains, may, in some measure, account for the different results obtained by different chemists in their attempts to ascertain its proportions.

4. Fourcroy has observed, that when oxymuriatic acid gas is made to pass through the red oxide of mercury, it combines with an additional dose of oxygen, and is converted into a peroxide; but as this peroxide cannot be procured in a separate state, we are ignorant of its properties.

Mercury does not combine with carbon or hydrogen; but it unites readily with sulphur and with phosphorus.

When two parts of sulphur and one of mercury are triturated together in a mortar, the mercury gradually disappears, and the whole assumes the form of a black powder, formerly called ethiops mineral. It is scarcely possible by any process to combine the sulphur and mercury so completely, that small globules of the metal may not be detected by a microscope. When mercury is added slowly to its own weight of melted sulphur, and the mixture is constantly stirred, the same black compound is formed.

Fourcroy had suggested, that in this compound the mercury is in the state of black oxide, absorbing the necessary portion of oxygen from the atmosphere during its combination with the sulphur. But the late experiments of Proust have shewn that this is not the case. Berthollet has made it probable that ethiops mineral contains sulphureted hydrogen. Hence we must consider it as composed of three ingredients, namely, mercury, sulphur, and sulphureted hydrogen. Such compounds are at present denominated by chemists hydrogenous sulphurets. Ethiops mineral of course is an hydrogenous sulphuret of mercury. When this substance is heated, part of the sulphur is dissipated, and the compound assumes a deep violet colour.

When heated red-hot, it sublimes; and if a proper vessel is placed to receive it, a cake is obtained of a fine red colour. This cake was formerly called cinnabar; and when reduced to a fine powder, is well known in commerce under the name of vermilion. It has been hitherto supposed a compound of the oxide of mercury and sulphur. But the experiments of Proust have demonstrated that the mercury which it contains is in the metallic state. According to that very accurate chemist, it is composed of 85 parts of mercury and 15 of sulphur. It is therefore sulphuret of mercury.

The sulphuret of mercury has a scarlet colour, more or less beautiful, according to the mode of preparing it. Its specific gravity is about 10. It is tasteless, insoluble in water, and in muriatic acid, and not altered by exposure to the air. When heated sufficiently, it takes fire, and burns with a blue flame. When mixed with half its weight of iron filings, and distilled in a stone-ware retort, the sulphur combines with the iron, and the mercury passes into the receiver, which ought to contain water. By this process mercury may be obtained in a state of purity. The use of sulphuret of mercury as a paint is well known.

Mr. Pelletier, after several unsuccessful attempts to combine phosphorus and mercury, at last succeeded by distilling a mixture of red oxide of mercury and phosphorus. Part of the phosphorus combined with the oxygen of the oxide, and was converted into an acid; the rest combined with the mercury. He observed that the mercury was converted into a black powder before it combined with the phosphorus. As Pelletier could not succeed in his attempts to combine phosphorus with mercury in its metallic state, we must conclude that it is not with mercury, but with the black oxide of mercury, that the phosphorus combines. The compound, therefore, is not phosphorus of mercury, but black phosphureted oxide of mercury.

It is of a black colour, of a pretty solid consistence, and capable of being cut with a knife. When exposed to the air, it exhales vapours of phosphorus.

Mercury does not combine with the simple incombustibles.

Mercury combines with the greater number of metals. These combinations are known in chemistry by the name of amalgams.

The amalgam of gold is formed very readily, because there is a very strong affinity between the two metals. If a bit of gold is dipped into mercury, its surface, by combining with mercury, becomes as white as silver. The easiest way of forming this amalgam is to throw small pieces of red-hot gold into mercury. The proportions of the ingredients are not determinable, because the amalgam has an affinity both for the gold and the mercury; in consequence of which they combine in any proportion. This amalgam is white, with a shade of yellow; and when composed of six parts of mercury and one of gold, it may be obtained crystallized in four-sided prisms. It melts at a moderate temperature; and when heated sufficiently, the mercury evaporates, and leaves the gold in a state of purity. It is much used in gilding. The amalgam composed of ten parts of mercury and one of gold, is spread upon the metal which is to be gilt; and then, by the application of a gentle and equal heat, the mercury is driven off, and the gold left adhering to the metallic surface; this surface is then rubbed with a brass-wire brush under water, and afterwards burnished.

Dr. Lewis attempted to form an amalgam of platinum, but hardly succeeded after a labour which lasted for several weeks. Guyton Morveau succeeded by means of heat. He fixed a small cylinder of platinum at the bottom of a tall glass vessel, and covered it with mercury. The vessel was then placed in a sand-bath, and the mercury kept constantly boiling. The mercury gradually combined with the platinum; the weight of the cylinder was doubled, and it became brittle. When heated strongly, the mercury evaporated, and left the platinum partly oxidated. It is remarkable, that the platinum, notwithstanding its superior specific gravity, always swam upon the surface of the mercury, so that Morveau was under the necessity of fixing it down.

The amalgam of silver is made in the same manner as that of gold, and with equal ease. It forms dentritical crystals, which, according to the Dijon academicians, contain eight parts of mercury and one of silver. It is of a white colour, and is always of a soft consistence. Its specific gravity is greater than the mean of the two metals. Gellert has even remarked that, when thrown into pure mercury, it sinks to the bottom of that liquid. When heated sufficiently, the mercury is volatilized, and the silver remains behind pure.

The affinities of mercury as ascertained by Morveau, and of its oxides as exhibited by Bergman, are in the following order:

Mercury.	Oxide of Mercury.
Gold,	Muriatic acid,
Silver,	Oxalic,
Tin,	Succinic,
Lead,	Arsenic,
Bismuth,	Phosphoric,
Platinum,	Sulphuric,
Zinc,	Saclactic,
Copper,	Tartaric,
Antimony,	Citric,
Arsenic,	Sulphurous,
Iron.	Nitric,
	Fluoric,
	Acetic,
	Boracic,
	Prussic,
	Carbonic.

Mercury, in astronomy, the smallest of the planets, and the nearest the sun. See Astronomy.

MERGUS, in ornithology, a genus of birds of the order of anseres; distinguished by having the beak of a cylindrical figure, and hooked at the extremities, and its denticulations of a subulated form.

1. The cucullatus, or crested diver of Catesby, has a globular crest, white on each side; and the body is brown above, and white below. This elegant species inhabits North America. It appears at Hudson's-bay the end of May, and builds close to the lakes. The nest is composed of grass, lined with feathers from the breast; the number of eggs from four to six. The young are yellow, and are fit to fly in July. They all depart from thence in autumn. They appear at New York, and other parts, as low as Virginia and Carolina, in November, where they frequent fresh waters. They return to the north in March, and are called at Hudson's-bay omiska sheep. See Plate Nat. Hist. fig. 265.

2. The merganser, or goosander, weighs four pounds; its length is two feet four inches; the breadth three feet four. The dun-diver, or female, is less than the male; the head and upper part of the neck are ferruginous; the throat white; the feathers on the hind part are long, and form a pendant crest; the back, the coverts of the wings, and the tail, are of a deep ash-colour; the greater quill-feathers are black, the lesser white; the breast and middle of the belly are white, tinged with yellow. The goosander seems to prefer the more northern situations to those of the south, not being seen in the last except in very severe seasons. It continues the whole year in the Orkneys; and has been shot in the Hebrides in summer. It is common on the continent of Europe and Asia, but most so towards the north.

3. The albellus, or smew, weighs about 34 ounces; the length is 18 inches, the breadth 26; the bill is near two inches long, and of a lead-colour; the head is adorned with a long crest, white above and black beneath; the head, neck, and whole under part of the body, are of a pure white; the tail is of a deep ash-colour, the legs a blueish grey. The female, or lough-diver, is less than the male; the back, the scapulars, and the tail, are dusky; the belly is white. The smew is seen in England only in winter, at which season it will sometimes be met with at the southern parts of it; as also in France, in the neighbourhood of Picardy, where it is called la piette: similar to this, we have heard it called in Kent by the name of magpie-diver.

There are three other species.

MERIDIAN. See Astronomy, and Geography.

MERIDIONAL PARTS, MILES, or MINUTES, in navigation, are the parts by which the meridians in Mr. Wright's chart (commonly though falsely called Mercator's) increase as the parallels of latitude decrease: and as the cosine of the latitude of any place is equal to the radius or semi-diameter of that parallel, therefore, in the true sea-chart, or nautical planisphere, this radius being the radius of the equinoctial, or whole sine of 90°, the meridional parts at each degree of latitude must increase, as the secants of the arch, contained between that latitude and the equinoctial, do decrease. The tables therefore of meridional parts, which we have in books of navigation, are made by a continual addition of secants; they are calculated in some books for every degree and minute of latitude; and they will serve either to make or graduate a Mercator's chart, or to work the Mercator's sailing. To use them, you must enter the table with the degree of latitude at the head, and the minute on the first column towards the left hand, and in the angle of meeting you will have the meridional parts. Having the latitudes of two places, to find the meridional miles or minutes between them: Consider whether one of the places lies on the equator, or both on the same side of it; or, lastly, on different sides. 1. If one of the proposed places lies on the equator, then the meridional difference of latitude is the same with the latitude of the other place, taken from the table of meridional parts. 2. If the two proposed places be on the same side of the equator, then the meridional difference of latitude is found by subtracting the meridional parts answering to the least latitude, from those answering to the greatest, and the difference is that required. 3. If the places lie on different sides of the equator, then the meridional difference of latitude is found by adding together the meridional parts answering to each latitude, and the sum is that required.

To find the Meridional Parts *to any Spheroid, with the same exactness as in a Sphere.* Let the semi-diameter of the equator be to the distance of the centre from the focus of the generating ellipse, as m to 1. Let A represent the latitude for which the meridional parts are required, s the sine of the latitude, to the radius 1: find the arc B, whose sine is $\frac{s}{m}$; take the logarithmic tangent of half the complement of B, from the common tables; subtract the log. tangent from 10.0000000, or the log. tangent of 45°: multiply the remainder by the number 7915.7044679, and divide the product by m; then the quotient subtracted from the meridional parts in the sphere, computed in the usual manner for the latitude A, will give the meridional parts, expressed in minutes, for the same latitude in the spheroid, when it is the oblate one.

Example. If mm : 1 :: 1000 : 22, then the greatest difference of the meridional parts in the sphere and spheroid is 76.0929 minutes. In other cases it is found by multiplying the remainder above-mentioned by the number 1174.078.

When the spheroid is oblong, the difference in the meridional parts between the sphere and spheroid, for the same latitude, is then determined by a circular arc.

We shall here add a table of meridional parts, calculated both for the sphere and oblate spheroid, by the reverend Mr. Murdoch, in his new and learned Treatise of Mercator's Sailing applied to the true Figure of the Earth. By this table may be projected a true chart for any part of the earth's surface, and the several problems of sailing may be solved by it. Maps of countries may be delineated and applied to the various purposes of navigation, geography, and astronomy. Nor are the errors of the common spherical projections so very small in many cases, as to be inconsiderable and not dangerous. For instance, if a ship sails from south latitude 25°, to north latitude 30°, and the angle of the course be 43°; then the difference of longitude by the common table would be 3206′, exceeding the true difference 3141′ by 65′, or miles. Also the distance sailed would be 4512, exceeding the true distance, 4423, by 89′, or miles; which differences are too great to be neglected. For other instances of such a correction of the charts, we refer to the author's admirable book above-mentioned.

A TABLE

Of Meridional Parts to the Spheroid and Sphere, with their Differences.

D.	Spheroid.	Sphere.	Diff.
1	58.7	60.0	1. 3
2	117.3	120.0	2. 7

MERLIN. See Falcon.

MERLON, in fortification, is that part of a parapet which is terminated by two embrasures of a battery. Its height and thickness are the same with those of the parapet; but its breadth is generally nine feet on the inside, and six on the outside. It serves to cover those on the battery from the enemy; and is better when made of earth well beaten and close, than when built with stones; because they fly about and wound those they should defend.

MEROPS, in ornithology, a genus belonging to the order of picæ. The bill is crooked, flat, and carinated; the tongue is jagged at the point; and the feet are of the walking kind. The principal species are, 1. The apiaster, or bee-eater, which has an iron-coloured back; the belly and tail are of a blueish green; and the throat yellow. This bird inhabits various parts of Europe, on the continent, though not in England; yet is said to have been seen in Sweden, and flocks of them have been met with at Anspach in Germany in the month of June. It takes the name of bee-eater from its being very fond of those insects; but, besides these, it will catch gnats, flies, cicadæ, and other insects, on the wing, like swallows. These birds make their nests in the holes in the banks of rivers, like the sand martin and kingsfisher; at the end of which the female lays from five to seven white eggs, rather less than those of a blackbird. The nest itself is composed of moss. 2. The viridis, or Indian bee-eater, is green, with a black belt on the breast; and the throat and tail are black. It inhabits Bengal. 3. The erythropterus, or red-winged bee-eater, is in length six inches; the bill is one inch, and black; the upper parts of the head, body, wings, and tail-coverts, are green brown, deepest on the head and back, lightest on the rump and tail-coverts; behind the eye is a spot of the same, but of a very deep colour; the quills and tail are red, tipped with black; the last two inches in length; the throat is yellow; the under parts of the body are a dirty white; and the legs black. There are more than 20 other species.

MESEMBRYANTHEMUM, *fig-marigold*, a genus of the pentagynia order, in the icosandria class of plants, and in the natural method ranking under the 13th order, succulentæ. The calyx is quinquefid; the petals are numerous and linear; the capsule is fleshy, inferior, and monospermous. There are seventy-five species, all African plants, from the Cape of Good Hope, near 40 of which are retained in our gardens for variety. Of these only one is annual, and the most remarkable of them all: it is called the crystallinum, diamond, ficoides, or ice-plant. This singular and curious plant, being closely covered with large pellucid pimples, full of moisture, shining brilliantly like diamonds, is in great esteem. It is a very tender plant while young, and is raised annually from seed by means of hotbeds. In June it will endure the open air till October, when it perishes; but if placed in a hot-house in autumn it will often live all winter.

The other species are most durable in stem and foliage. Some are shrubby; others pendulous, with loose straggling stems, and branches inclining to the ground; while others have no stalks at all; their leaves are universally very thick, succulent, fleshy, and of many various shapes, situations, and directions; while some are punctured, or dotted with transparent points; and some have pellucid pimples, as already mentioned. They afford a very agreeable variety at all times of the year, and merit a place in every collection. They are greenhouse plants, and are propagated by cuttings of their stalks and branches.

MESENTERY. See ANATOMY.

MESNE, he who is lord of a manor, and so hastenants holding of him, yet himself holds of a superior lord. 15 Vin. Abr.

MESNE PROCESS, is an intermediate process, which issues pending the suit, upon some collateral interlocutory matter, as to summon juries, witnesses, and the like; sometimes it is put in contradistinction to final process, or process of execution; and then it signifies all such process as intervenes between the beginning and end of a suit. 3 Black. 279.

MESPILUS, the medlar; a genus of the pentagynia order, in the icosandria class of plants; and in the natural method ranking under the 36th order, pomaceæ. The calyx is quinquefid; the petals are five; the berry is inferior and pentaspermous.

There are nine species, the principal of which are, 1. The Germanica, German mespilus, or common medlar, rises with a deformed tree-stem, branching irregularly 15 or 20 feet high; spear-shaped leaves, and brown fruit, the size of middling apples, which ripen in October, but are not eatable till beginning to decay. The varieties are, common great German medlar; smaller Nottingham medlar; spear-shaped Italian medlar. 2. The arbutifolia, arbutus-leaved mespilus, has a small, roundish, purple fruit, like haws. 3. The amelanchier, or shrubby medlar, with black fruit. 4. The chamæmespilus, or dwarf medlar, commonly called bastard quince, has small red fruit. 5. The cotoneaster, commonly called dwarf quince, with small roundish bright-red fruit. 6. The Cadanensis, Canada snowy mespilus, with small, purplish fruit, like haws. 7. The pyracantha, or evergreen thorn, rises with a shrubby, spinous stem, branching diffusely 12 or 14 feet high, all the shoots terminated by numerous clusters of whitish flowers; succeeded by large bunches of beautiful red berries, remaining all winter, and exhibiting a very ornamental appearance.

MESSENGERS, are certain officers chiefly employed under the direction of the secretaries of state, and always in readiness to be sent with all kinds of dispatches foreign and domestic. They also, by virtue of the secretaries' warrants, take up persons for high treason, or other offences against the state. The prisoners they apprehend are usually kept at their own houses, for each of which they are allowed 6s. 8d. per day, by the government: and when they are sent abroad, they have a stated allowance for their journey.

METALS may be considered as the great instruments of all our improvements: without them, many of the arts and sciences could hardly have existed. So sensible were the antients of their great importance, that they raised those persons who first discovered the art of working them to the rank of deities. In chemistry, they have always filled a conspicuous station: at one period the whole science was confined to them; and it may be said to have owed its very existence to a rage for making and transmuting metals.

1. One of the most conspicuous properties of the metals is a particular brilliancy which they possess, and which has been called the metallic lustre. There are other bodies indeed (mica for instance) which apparently possess this peculiar lustre, but in them it is confined to the surface, and accordingly disappears when they are scratched, whereas it pervades every part of the metals. This lustre is occasioned by their reflecting much more light than any other bodies; a property which seems to depend partly on the closeness of their texture. This renders them peculiarly proper for mirrors, of which they always form the basis.

2. They are perfectly opaque, or impervious to light, even after they have been reduced to very thin plates. Silver leaf, for instance, $\frac{1}{160000}$ of an inch thick, does not permit the smallest ray of light to pass through it. Gold, however, when very thin, is not absolutely opaque: for gold leaf, $\frac{1}{280000}$ of an inch thick, when held between the eye and the light, appears of a lively green; and must therefore, as Newton first remarked, transmit the green-coloured rays. It is not improbable that all other metals, as the same philosopher supposed, would also transmit light if they could be reduced to a proper degree of thinness. It is to this opacity that a part of the excellence of the metals, as mirrors, is owing; their brilliancy alone would not qualify them for that purpose.

3. They may be melted by the application of heat, and even then still retain their opacity. This property enables us to cast them in moulds, and then to give them any shape we please. In this manner many elegant iron utensils are formed. Different metals differ exceedingly from each other in fusibility. Mercury is so very fusible, that it is always fluid at the ordinary temperature of the atmosphere; while other metals, as platinum, cannot be melted except by the most violent heat which it is possible to produce.

4. Their specific gravity is much greater than that of any other body at present known. Antimony, one of the lightest of them, is more than six times heavier than water; and the specific gravity of platinum, the heaviest of all the metals, is 23. This great density, no doubt, contributes considerably to the reflection of that great quantity of light which constitutes the metallic lustre.

5. They are the best conductors of electricity of all the bodies hitherto tried.

6. None of the metals are very hard; but some of them may be hardened by art to such a degree as to exceed the hardness of almost all other bodies. Hence the numerous cutting instruments which the moderns make of steel, and which the antients made of a combination of copper and tin.

7. The elasticity of the metals depends upon their hardness; and it may be increased by the same process by which their hardness is increased. Thus the steel of which the balance-springs of watches are made, is almost perfectly elastic, though iron in its natural state possesses but little elasticity.

8. But one of their most important properties is malleability, by which is meant the capacity of being extended and flattened when struck with a hammer. This property, which is peculiar to metals, enables us to give the metallic bodies any form we think proper, and thus renders it easy for us to convert them into the various instruments for which we have occasion. All metals do not possess this property; but it is remarkable that almost all those which were known to the antients have it. Heat increases this property considerably. Metals become harder and denser by being hammered.

9. Another property, which is also wanting in many of the metals, is ductility; by which we mean the capacity of being drawn out into wire, by being forced through holes of various diameters.

10. Ductility depends, in some measure, on another property which metals possess, namely, tenacity; by which is meant the power which a metallic wire of a given diameter has of resisting, without breaking, the action of a weight suspended from its extremity. Metals differ exceedingly from each other in their tenacity. An iron wire, for instance, $\frac{1}{10}$th of an inch in diameter, will support, without breaking, about 500lb. weight; whereas a lead wire, of the same diameter, will not support above 29lb.

11. When exposed to the action of heat and air, most of the metals lose their lustre, and are converted into earthy-like powders of different colours and properties, according to the metal and the degree of heat employed. Several of the metals even take fire when exposed to a strong heat; and after combustion the residuum is found to be the very same earthy-like substance.

12. If any of these calces, as they are called, is mixed with charcoal-powder, and exposed to a strong heat in a proper vessel, it is changed again to the metal from which it was produced. This fact is easily explained on the principles of modern chemistry; the calx is the metal combined with oxygen, or an oxide, in modern language, and by heating it with charcoal, which has a stronger attraction for oxygen, that substance is taken from the metal, and it is brought again to the metallic state. The oxygen in this process, uniting with the charcoal, forms carbonic acid gas.

The words calx and calcination, then, are evidently improper, as they convey false ideas; philosophers therefore now employ, instead of them, the words oxide and oxidizement, which were invented by the French chemists. A metallic oxide signifies a metal united with oxygen; and oxidizement implies the act of that union.

13. Metals, then, are all capable of combining with oxygen; and this combination is sometimes accompanied by combustion, and sometimes not. The new compounds formed are called metallic oxides, and in some cases metallic acids. These were formerly distinguished from each other by their colour. One of the oxides, for instance, was called black oxide, another was termed red oxide; but it is now known that the same oxide is capable of assuming different colours according to circumstances. The mode of naming them from their colour, therefore, wants precision, and is apt to mislead; especially as there occur different examples of two distinct oxides of the same metal having the same colour.

As it is absolutely necessary to be able to distinguish the different oxides of the same metal from each other with perfect precision, and as the present chemical nomenclature is defective in this respect, we may, till some better method is proposed, distinguish them from each other, by prefixing to the word oxide the first syllable of the Greek ordinal numerals. Thus the protoxide of a metal will denote the metal combined with a minimum of oxygen, or the first oxide which the metal is capable of forming; deutoxide will denote the second oxide of a metal, or the metal combined with two doses of oxygen. When a metal has combined with as much oxygen as possible, the compound formed is denoted by the term peroxide; indicating by it, that the metal is thoroughly oxidized.

Thus we have the term oxide to denote the combination of metals with oxygen in general; the terms protoxide and peroxide to denote the minimum and maximum of oxidizement; and the terms deutoxide, tritoxide, &c. to denote all the intermediate states which are capable of being formed.

14. Metals are capable also of combining with the simple combustibles. The compounds thus formed are denoted by the simple combustible which enters into the combination, with the termination uret added to it. Thus the combination of a metal with sulphur, phosphorus, or carbon, is called the sulphuret, phosphuret, or carburet of the metal. Hydrogen has not been proved capable of entering into similar combinations; neither have the simple incombustibles.

15. The metals are capable likewise of combining with each other, and of forming compounds, some of which are extremely useful in the manufacture of instruments and utensils. Thus pewter is a compound of lead and tin; brass, a compound of copper and zinc; bell-metal, a compound of copper and tin. These metallic compounds are called by chemists alloys, except when one of the combining metals is mercury. In that case the compound is called an amalgam. Thus the compound of mercury and gold is called the amalgam of gold.

16. The metals at present amount to 23; only 11 of which were known before the year 1730. They may be very conveniently arranged under three classes; namely, 1. Malleable metals; 2. Brittle and easily fusible metals; 3. Brittle and difficultly fusible metals. The metals belonging to each of these classes will be seen from the following Table:

Malleable (formerly called perfect metals).

1. Gold,	2. Platinum,	3. Silver,
4. Mercury,	5. Copper,	6. Iron,
7. Tin,	8. Lead,	9. Nickel,
10. Zinc.		

Brittle, and easily fused.

1. Bismuth,	2. Tellurium,
3. Antimony,	4. Arsenic.

Brittle, and difficultly fused.

1. Cobalt,	2. Manganese,
3. Tungsten,	4. Molybdenun,
5. Uranium,	6. Titanium,
7. Chromium,	8. Columbium,
9. Tantolium.	

The antients gave to the seven following metals the names of the planets, and denoted each of them by particular marks, which represented both the planet and the metal:

Gold was the	Sun, and represented by	☉
Silver . . .	Moon, ...	☾
Mercury . .	Mercury, ...	☿
Copper . .	Venus, ...	♀
Iron	Mars, ...	♂
Tin	Jupiter, ...	♃
Lead	Saturn, ...	♄

It seems most probable that these names were first given to the planets; and that the seven metals, the only ones then known, were supposed to have some relation to the planets or to the Gods that inhabited them, as the number of both happened to be the same. It appears from a passage in Origen, that these names first arose among the Persians. Why each particular metal was denominated by a particular planet, it is not easy to see. Many conjectures have been made, but scarcely any of them are satisfactory.

As to the characters by which these metals were expressed, astrologers seem to have considered them as the attributes of the deities of the same nature. The circle, in the earliest periods among the Egyptians, was the symbol of divinity and perfection; and seems with great propriety to have been chosen by them as the character of the sun, especially as, when surrounded by small strokes projecting from its circumference, it may form some representation of the emission of rays. The semicircle is, in like manner, the image of the moon; the only one of the heavenly bodies that appears under that form to the naked eye. The character ♄ is supposed to represent the scythe of Saturn; ♃ the thunderbolt of Jupiter; ♂ the lance of Mars, together with his shield; ♀ the looking-glass of Venus; and ☿ the caduceus or wand of Mercury.

Professor Beckmann, however, who has examined this subject with much attention, thinks that these characters are mere abbreviations of the old names of the planets. "The character of Mars (he observes), according to the oldest mode of representing it, is evidently an abbreviation of the word Θουρος, under which the Greek mathematicians understood that deity; or, in other words, the first letter Θ, with the last letter ς placed above it. The character of Jupiter was originally the initial letter of Ζευς; and in the oldest manuscripts of the mathematical and astrological works of Julius Firmicus, the capital Z only is used, to which the last letter ς was afterwards added at the bottom, to render the abbreviation more distinct. The supposed looking-glass of Venus is nothing else than the initial letter distorted a little of the word Φωσφορος, which was the name of that goddess. The imaginary scythe of Saturn has been gradually formed from the two first letters of his name Κρονος, which transcribers, for the sake of dispatch, made always more convenient for use, but at the same time less perceptible. To discover in the pretended caduceus of Mercury the initial letter of his Greek name Στιλβων, one needs only look at the abbreviations in the oldest manuscripts, where he will find that the Σ was once written as C; they will remark also that transcribers, to distinguish this abbreviation from the rest still more, placed the C thus ◡, and added under it the next letter τ. If those to whom this deduction appears improbable will only take the trouble to look at other Greek abbreviations, they will find many that differ still farther from the original letters they express than the present character ☿ from the C and τ united. It is possible also that later transcribers, to whom the origin of this abbreviation was not known, may have endeavoured to give it a greater resemblance to the caduceus of Mercury. In short, it cannot be denied that many other astronomical characters are real symbols, or a kind of proper hieroglyphics, that represent certain attributes or circumstances, like the characters of Aries, Leo, and others, quoted by Saumaise."

METALLURGY. When it is once ascertained that an ore of metal may be worked with advantage, the metallurgist proceeds in his operations: first extracting the ore by all the mechanical methods the art possesses; which consist in digging shafts, opening adits, employing various machines to raise the water, renew the air, bring up the ore, favour the ascent and descent of the miner, prevent the earth from giving way, &c.

In general, after having bored the ground which contains ores, or having ascertained their existence by various indications, a square perpendicular well, or shaft, is dug in the ground, sufficiently wide to place straight ladders in it; over which machinery is fixed, for the purpose of raising and lowering vessels, and in which it is sometimes necessary to fix pumps to draw off the water which is collected. If the ore is too deep for a single shaft to lead from the grass or surface, to the vein at the bottom of the first shaft, a horizontal gallery is opened, at the end of which a second shaft is sunk, and in this manner the workmen proceed until they arrive at the bottom of the mine.

When the rock to be perforated is hard, solid, and capable of supporting itself, the shaft will not require to be guarded within; but if it is soft and friable, if it threatens to fall in during the excavation, it becomes necessary to support the shaft and gallery with pieces of wood-work, covered with planks all round, in order to support the earth and retain the fragments, which from time to time would separate, and might maim the workmen.

One of the most important particulars of the art of exploring mines, is the renovation of the air. When it is practicable to open a gallery which shall lead from the bottom of the shaft to the day or open air, a current is easily established by this simple artifice. When this is not possible, a second shaft is sunk to the extremity of the gallery, opposite to that where the first was sunk. When one of these shafts opens at a different level from the other, the circulation and renewal of the air are easy. If the second shafts are of equal height, the current will not take place spontaneously, but must be determined by causing them to communicate with a lighted furnace.

The danger of waters which overflow the works, and retard the operations, at the same time that they threaten the safety of the workmen, is no less necessary to be provided against. If the water transudes gradually through the earth, it may be let off into the plain or the nearest river by means of a horizontal adit. If it is collected in a greater quantity, or if it is not possible to open such an adit, the water is extracted by pumps, which are moved either by a stream, or by a pond, or by vapour of water introduced, and condensed in cylinders. These last machines, called steam-engines, are at present much more common than formerly. (See STEAM ENGINE.) It is an object of great difficulty sometimes to defend the works against enormous masses of water which rush forth when, in digging, a vast subterranean reservoir is opened. These cases happily are very rare; but they are in some measure provided against by a kind of moveable strong door, or barricado, which the workmen place at the moment when they find by the particular sound of the rock, that the waters are coming in upon them, which barricado, by separating them from the liquid, gives them time to save themselves.

The destructive elastic fluids, which so frequently are disengaged in the cavities of mines, and particularly the carbonic acid gas, and different species of mixed hydrogen gases, more or less pernicious, are also among the most formidable enemies of miners. Galleries, fires, ventilators, inflammations by means of torches held at a great distance in those parts of the mines which are mephitized by the inflammable gases, and particularly the various methods of causing fresh air to enter, are the only remedies which can be opposed to these subterraneous evils.

Few metals are found in a pure state; gold, silver, and sometimes copper, are exceptions. The other metals are generally found in the state of ores, in which they are mixed and blended with other substances, so as not to have the ductility or other qualities of metals: often, indeed, they have not the metallic lustre. Sometimes the ore is only a pure oxide, which requires no more than that the oxygen should be drawn from it by heating it with an inflammable substance. Such are all the ferruginous ochres, which are oxides of iron.

The ores of metals are generally found in the veins of mountains or rocky strata, and are always separated from the rocks on each side by a quantity of spar, quartz, or sometimes softer clay or earth. The spar is generally of the gypseous kind. These form the matrix of the ore; in English, called the rider. In different veins it is of different thicknesses; the quantity of the ore increasing as that of the matter which surrounds it diminishes. Often the ore is in branching masses wandering irregularly through it, and is often rudely mixed with the matrix in veins of different thicknesses. These are called brangled ores.

The veins or fissures of the rocky strata are sometimes only a few inches wide, and sometimes many yards. In rich mines there are immense masses of ore many feet broad. Where the veins happen not to be filled up, we find the ores crystallized round the cavity.

The ore, when separated from the matrix, generally contains some other matter; as sulphur, arsenic, or both: and sometimes an earthy substance, the whole being united into a compound which at first appears homogeneous.

The first operation on metals is to separate the ore from the matrix. When the ore is found in large masses, most of it may be dug up free from the matrix, and those pieces to which it adheres may be freed by a hammer. But as the ore is often intimately mixed with the matrix, it is necessary to try other methods.

Sometimes the whole is reduced to powder and thrown into water; the water is then put in motion, and the earthy matter floats above the ore, on account of their different specific gravity. It is still better to place the powder on a board, over which water may be made to run; being stirred while the water runs over it, the earthy parts float and are carried off, whilst the metallic parts remain behind. This operation is called washing the ore.

When the matrix is not divisible by water, a stamping-mill is employed, which consists of an axis turned by a water-wheel. On the axis there are a number of cogs, which lift up a perpendicular pillar of wood plated at bottom with iron; this falling down bruises the matrix to powder. It often happens that the matrix is harder than the ore, and in this case the ore will be reduced to a much finer powder than it. Here the ore is a much heavier substance; yet its surface may be so much increased, that it may be carried off by the water before the matrix. This may be obviated by subjecting the mass to a brisk heat, and throwing water upon it when red-hot, which renders the matrix more easy to be powdered. There are many ores of this kind which undergo a fusion by heat; hence the small particles of the matrix, which are angular and irregular, contract themselves into little spheres, by which means losing part of their surface, they become specifically heavier, and fall more readily to the bottom of the water: the ore too generally loses part of the sulphur it contains, and on this account becomes specifically heavier: the stone becomes softer, and is sometimes disposed to fall into powder merely by the application of water, especially if composed of gypseous spar. Quartz is not indeed so easily heated in this way, but it becomes softer by these means; cracks and flaws are produced in it, and of consequence it is more easily divided.

After all there will in washing be some loss of the metal: hence it is found more expedient to bring the whole mass into fusion, as is practised in Germany. The fusion is performed in some of the ordinary furnaces, and commonly with the addition of particular stones, or the scoriæ of former fusions, which greatly promote the fusion of the new matter. Thus the metallic matter settles to the bottom still in the state of an ore, whence the process is called crude separation. When the ore is thus freed from its matrix, the next operations are, to separate the sulphur, arsenic, &c. which the metals may contain; and this must be done by a mild heat, because of their strong adhesion to the metals, which the metallurgists call their rapacity. If exposed to a violent heat, the arsenic will hardly separate when forced off intensely, sometimes carrying off part of the metal along with it. This treating the ore in a gentle heat is called roasting it. The workmen commonly build the ore into heaps with fuel, so that the whole may become red-hot, and the air have free passage through it. Some ores, as those of copper, require many repetitions of the process, the sulphur and arsenic adhering so closely.

In consequence of this operation, the metal remains more or less in the form of an oxide; the operation of reduction becomes therefore necessary. It is often necessary to add earths to the ores, as they often contain earths not so easily fusible, but which by mixture with others become so. The fires being kept up for some time the ore melts; and as it passes through the fuel, which is generally charcoal of wood, the oxygen, which the oxide contained, is drawn off by the charcoal forming fixed air, and the metal falls into the bason constructed for that purpose in the furnace.

Thus the metal is obtained free from earthy and stony matter, and generally from arsenic and sulphur, but it contains other metals: thus copper has always with it more or less of iron, silver a quantity of copper, &c.

Some, as lead ores when rich, are treated by immediate fusion, without previous roasting; for though it would give a greater quantity of the metal, it would be too expensive. There are many ores in which the metal exists in the state of an oxide. Here previous roasting would be of no advantage. The ores of silver and gold require certain additions to them to attract the sulphur and arsenic, and to melt the other matter which is mixed with them, so as to dispose them to separate. See ASSAYING, &c.

METAPHOR, in rhetoric, a trope, by which we put a strange word for a proper word. See RHETORIC.

METAPHYSICS. It is remarkable that scarcely any two writers are agreed with respect to the meaning of the word metaphysics. One lexicographer tells us, somewhat obscurely, that it is "the doctrine of the general affections of substances existing." Another that "it is a science which treats of being as such in the abstract." While a third most gravely assures us, it means "that part of philosophy which considers the nature and properties of thinking beings." This last definition must evidently be unfounded, since "the nature and properties of thinking beings" are either a branch of natural philosophy or of logic. See LOGIC.

The word seems to have originated with Aristotle, who has termed a treatise which is placed after his Physics, μετα τα φυσικα. So that it may mean either something "beyond Physics," or merely "an appendix to his physics" or natural history. This treatise chiefly relates to the intellectual world.

The mode in which authors have treated of metaphysics is as various as their definitions of the term. One author, under the form of a treatise of metaphysics, presents us with a discussion on abstract words, their meaning and application; another with an enquiry into the faculties and operations of the human mind; a third with a volume of theology, a dissertation on the being and attributes of God, and the nature of spiritual and celestial intelligences; and a fourth with a treatise of ethics or moral philosophy.

A science so subtle, so indefinite, so evasive, which, under so many Proteus forms, eludes our grasp, is scarcely a proper subject for a practical work like this. What are metaphysics? Every thing! Nothing! Yet there are some subjects which the learned have agreed in calling metaphysical: such were the discussions between Clarke and Leibnitz concerning the free agency of man; such were the disputes concerning identity and diversity which formerly agitated the schools, and those upon the origin of evil; and if we were called upon to point out a most able and rational work, into which metaphysics are introduced with propriety and ability, we should name Cudworth's Intellectual System.

METATARSUS. See Anatomy.

METEOR. This term is by some writers made to comprehend all the visible phenomena of meteorology, but it is more generally confined to luminous bodies appearing suddenly at uncertain times, and with more or less of motion in the atmosphere. These may be reduced under three classes, viz. fire-balls, falling or shooting stars, and ignes fatui.

Those phenomena which are classed together under the general appellation of fire-balls, were divided by the antients into several species, according to the external form or appearance which they assumed. They were also regarded by them in a much more formidable light than by us; as being the certain prognostics of great and awful events in the moral and political world. Even the philosophic Cicero himself speaks of the "ab occidente faces," as the certain harbingers or indications of those bloody scenes which in his time convulsed and desolated the Roman commonwealth.

Under the general name of comets, Pliny enumerates a variety of these phenomena. If the fire commences at one extremity of the meteor, and burns by degrees, he terms it, from its form and appearance, a lamp or torch; if an extended mass of fire passes longitudinally through the atmosphere, he calls it a dart; and if its length and magnitude are considerable, and it maintains its station for any space of time, it is a beam; and if the clouds seem to part, and emit a quantity of fire, he terms it a chasm; but this last appears to be, strictly speaking, an electrical phenomenon, indeed only a strong and vivid flash of lightning.

Several instances of these meteors are recorded by the same author. During the spectacle of gladiators exhibited by Germanicus, one of them passed rapidly by the faces of the spectators at noon-day. A meteor of that species which he calls a beam, he adds, was seen when the Lacedemonians were defeated at sea, in that memorable engagement which lost them the empire at sea. He also mentions a sanguineous kind of meteor, a flame as red as blood, which fell from heaven about the 107th Olympiad, when Philip of Macedon was concerting his wicked plan for enslaving the republics of Greece. He relates, that when he was himself on the watch during the night in the Roman camp, he was a spectator of a similar appearance—a number of resplendent lights fixed upon the palisadoes of the camp, similar, he says, to those which mariners speak of as attaching themselves to the masts and yards of a ship.

In tropical climates these meteors are more common and more stupendous than in these more temperate regions. "As I was riding in Jamaica," says Mr. Barbham, "one morning from my habitation, situated about three miles north-west from St. Jago de la Vega, I saw a ball of fire, appearing to me about the bigness of a bomb, swiftly falling down with a great blaze. At first I thought it fell into the town; but when I came nearer, I saw many people gathered together, a little to the southward, in the savannah, to whom I rode up, to inquire the cause of their meeting: they were admiring, as I found, the ground's being strangely broken up and ploughed by a ball of fire, which, as they said, fell down there. I observed there were many holes in the ground; one in the middle of the bigness of a man's head, and five or six smaller round about it, of the bigness of one's fist, and so deep as not to be fathomed by such implements as were at hand. It was observed also, that all the green-herbage was burnt up near the holes; and there continued a strong smell of sulphur near the place for some time after."

Ulloa gives an account of one of a similar kind at Quito. "About nine at night," says he, "a globe of fire appeared to rise from the side of the mountain Pichinca, and so large, that it spread a light over all the part of the city facing that mountain. The house where I lodged looking that way, I was surprised with an extraordinary light darting through the crevices of the window-shutters. On this appearance, and the bustle of the people in the street, I hastened to the window, and came time enough to see it, in the middle of its career, which continued from west to south, till I lost sight of it, being intercepted by a mountain that lay between me and it. It was round, and its apparent diameter about a foot. I observed it to rise from the sides of Pichinca, although, to judge from its course, it was behind that mountain where this congeries of inflammable matter was kindled. In the first half of its visible course it emitted a prodigious effulgence, then it began gradually to grow dim; so that, upon its disappearing behind the intervening mountain, its light was very faint."

Meteors of this kind are very frequently seen between the tropics; but they sometimes also visit the more temperate regions of Europe. We have the description of a very extraordinary one, given us by Montanari, that serves to shew to what great heights, in our atmosphere, these vapours are found to ascend. In the year 1676, a great globe of fire was seen at Bononia, in Italy, about three quarters of an hour after sunset. It passed westward with a most rapid course, and at the rate of not less than 160 miles in a minute, which is much swifter than the force of a cannon ball, and at last stood over the Adriatic sea. In its course it crossed over all Italy; and, by computation, it could not have been less than 38 miles above the surface of the earth. In the whole line of its course, wherever it approached, the inhabitants below could distinctly hear it, with a hissing noise, resembling that of a firework. Having passed away to sea, towards Corsica, it was heard at last to go off with a most violent explosion, much louder than that of a cannon; and immediately after, another noise was heard like the rattling of a great cart upon a stony pavement, which was probably nothing more than the echo of the former sound. Its magnitude, when at Bononia, appeared twice as long as the moon one way, and as broad the other; so that, considering its height, it could not have been less than a mile long, and half a mile broad. From the height at which this was seen, and there being no volcano in that quarter of the world whence it came, it is more than probable that this terrible globe was kindled on some part of the contrary side of the globe; and thus, rising above the air, and passing in a course opposite to that of the earth's motion, in this manner it acquired its amazing rapidity.

Two of these meteors appeared in this country in the year 1783, of which a most particular and truly philosophical account and ingenious solution, by Dr. Blagden, are published in the Philosophical Transactions of the following year; and as his account will apply to many phenomena of the kind, we cannot take any better method to elucidate this part of the subject, than by presenting our readers with a short abstract of this very curious and learned memoir.

The first of the two meteors in question was seen on the 18th of August, and was, in appearance, a luminous ball, which rose in the N. N. W. nearly round: it, however, soon became elliptical, and gradually assumed a tail as it ascended, and, in a certain part of its course, seemed to undergo a remarkable change, compared to bursting; after which it proceeded no longer as an entire mass, but was apparently divided into a cluster of balls of different magnitudes, and all carrying or leaving a train behind, till, having passed the east, and verging considerably to the south, it gradually descended, and was lost out of sight. The time of its appearance was about sixteen minutes past nine in the evening, and it was visible about half a minute. It was seen in all parts of Great Britain, at Paris, at Nuits in Burgundy, and even at Rome; and is supposed to have described a tract of 1000 miles at least over the surface of the earth. It appears to have burst and re-united several times; and the first bursting of it which was noticed seems to have been somewhere over Lincolnshire, perhaps near the commencement of the fens. This change in the meteor corresponds with the period in which it suffered a deviation from its course. If, indeed, the explosion was any kind of effort, we cannot wonder that the body should be diverted by it from its direct line; and, on the other hand, it seems equally probable, that if it was forced by any cause to change its direction, the consequence would naturally be a separation of its parts.

The illumination of these meteors is often so great as totally to obliterate the stars, to make the moon look dull, and even to affect the spectators like the sun itself. When this meteor was observed at Brussels, the moon appeared quite red, but when it was passed, recovered its natural light. This effect, the doctor remarks, must have depended on the contrast of colour, and shews how large a proportion of the blue rays enters into that light which could even make the *silver* moon appear to have an excess of red. The body of the fire-ball, even before it burst, did not appear of an uniform brightness, but consisted of lucid and dull parts, which were constantly changing their respective positions, so that the whole effect was to some eyes like an internal agitation or boiling of the matter. By the best accounts that could be procured concerning the height of the meteor, it seems to have varied from 55 to 60 miles. In these two last particulars it seems to have wonderfully corresponded with some other phenomena of the same kind.

A report was heard some time after the meteor disappeared, and this report was loudest in Lincolnshire and the adjacent parts, and again in the eastern parts of Kent: the report we may therefore suppose to be the effect of the two explosions of the body, first over Lincolnshire, and afterwards when it entered the continent: a hissing sound was said also to have accompanied the progress of the meteor. Judging from the height of the meteor, its bulk is conjectured to have been not less than half a mile in diameter; and when we consider this bulk, its velocity cannot fail to astonish us, which is supposed to be at the rate of more than 40 miles in a second.

The other meteor, which appeared on the 4th of October, 1783, at 43 minutes past six in the evening, was much smaller than the former, and of a much shorter duration. It was first perceived to the northward, as a stream of fire, like the common shooting stars, but large; but presently burst out into that intensely bright blueish flame, which is peculiar to such meteors. It left behind it a dusky-red streak of fire, and, except this, had no tail, but was nearly globular. After moving not less than 10 degrees in this bright state, it became suddenly extinct without any explosion. The height of the meteor must have been between 40 and 50 miles; and its duration was not more than three seconds.

The doctor is of opinion, that the general cause of these phenomena is electricity, which opinion he grounds upon the following circumstances: 1st, The velocity of these meteors, in which they correspond with no other body in nature but the electrical fluid. 2dly, The electrical phenomena attending meteors, the lambent flames, and the sparks proceeding from them, which have sometimes damaged ships and houses in the manner of lightning; and, added to these, the hissing sound, resembling that of electricity passing from a conductor. As a third argument in favour of this hypothesis, the doctor remarks the connection of meteors with the northern lights. Instances are recorded, where northern lights have been seen to join, and form luminous balls, darting about with great velocity, and even leaving a train like fire-balls. The aurora borealis appears to occupy as high, if not a higher, region above the surface of the earth, as may be concluded from the very distant countries to which it has been visible at the same time. 4thly, The most remarkable analogy, the doctor thinks, is the course of at least all the larger meteors, which seems to be constantly from or towards the north or north-west quarter of the heavens. Of above forty different fire-balls described in the Philosophical Transactions, twenty are so described, that it is certain their course was in that direction: only three or four seem to have moved the contrary way; and with respect to the remainder, it is left doubtful, from the imperfect state of the relations.

Notwithstanding the doctor's ingenious arguments, we cannot subscribe to the opinion, that these phenomena are altogether electrical. The duration of the fire-ball, the unequal consistency of the mass, and several other points in the narration, seem to indicate that its materials were of a less rare and evanescent nature than the electric fire.

The following probably was electrical.

On board the Montague, under the command of admiral Chambers, in lat. 42° 48′, long. 9° 3′, on the 4th of November 1749, about ten minutes before twelve, as the author, Mr. Chambers, was taking an observation, one of the quarter-masters desired he would look to the windward. On directing his eye that way, he observed a large ball of blue fire about three miles distance from them. They immediately lowered the top-sails, but it came so fast upon them, that before they could raise the main-tack, they observed the ball rise almost perpendicularly, and not above 40 or 50 yards from the main-chains, when it went off with an explosion as great as if hundreds of cannon had been discharged at the same time, leaving behind it a strong sulphureous smell. By this explosion, the main-topmast was shattered in pieces, and the main-mast rent quite down to the keel. Five men were knocked down, and one of them was greatly bruised, and some other damage of less importance was done to the ship. Just before the explosion, the ball seemed to be of the size of a large mill-stone.

The shooting or falling star is a common phenomenon; but though so frequently observed, the great distance and transient nature of these meteors have hitherto frustrated every attempt to ascertain their cause. The connection of these with an active state of the atmospheric electricity, is however certain from observation; and we have more reason to consider them as electric scintillæ than as solid or fluid matter in the act of combustion. They precede a change of wind.

Concerning the nature and composition of the *ignis fatuus*, or Will-with-a-wisp, there is less dispute; the generality of philosophers being agreed, that it is caused by some volatile vapour of the phosphoric kind, probably the phosphorized hydrogen gas. The light from putrescent substances, particularly putrid fish, and those sparks emitted from the sea, or sea-water when agitated, in the dark, correspond in appearance with this meteor. Sir Isaac Newton defines the ignis fatuus to be "a vapour shining without heat;" and it is usually visible in damp places, about dunghills, burying-grounds, and other situations which are likely to abound with phosphoric matter.

A remarkable ignis fatuus was observed by Mr. Derham, in some boggy ground, between two rocky hills. He was so fortunate as to be able to approach it within two or three yards. It moved with a brisk and desultory motion about a dead thistle, till a slight agitation of the air, occasioned, as he supposed, by his near approach to it, caused it to jump to another place; and as he approached, it kept flying before him. He was near enough to satisfy himself that it could not be the shining of glow-worms or other insects: it was one uniform body of light.

M. Beccaria mentions two of these luminous appearances, which were frequently observed in the neighbourhood of Bologna, and which emitted a light equal to that of an ordinary faggot. Their motions were unequal, sometimes rising, and sometimes sinking towards the earth; sometimes totally disappearing, though in general they continued hovering about six feet from the ground. They differed in size and figure; and, indeed, the form of each was fluctuating, sometimes floating like waves, and dropping sparks of fire. He was assured there was not a dark night in the whole year in which they did not appear; nor was their appearance at all affected by the weather, whether cold or hot, snow or rain. They have been known to change their colour from red to yellow; and generally grew fainter as any person approached, vanishing entirely when the observer came very near to them, and appearing again at some distance.

Dr. Shaw also describes a singular ignis fatuus, which he saw in the Holy Land. It was sometimes globular, or in the form of the flame of a candle; and immediately afterwards spread itself so much, as to involve the whole company in a pale inoffensive light, and then was observed to contract itself again, and suddenly disappear. In less than a minute, however, it would become visible as before, and run along from one place to another; or would expand itself over more than three acres of the adjacent mountains. The atmosphere at this time, he adds, was thick and hazy.

In a superstitious age we cannot wonder that these phenomena have all been attributed to supernatural agency: it is one of the noblest purposes of philosophy to release the mind from the bondage of imaginary terrors; and by explaining the modes in which the Divine Providence disposes the different powers of nature, to elevate our thoughts to the One First Cause; to teach us to see "God in all, and all in God."

METEORIC STONES. Almost all the larger fire-balls have been observed to disappear with a loud explosion; and it was almost constantly affirmed that heavy stony bodies fell from them. But though several well-authenticated accounts of the fall of such stones had been from time to time published, little credit was given to them; nor did they indeed attract the attention of philosophers, till Dr. Chladni published a dissertation on the subject in 1794. Two years after, Mr. King published a still more complete collection of examples, both antient and modern; many of them supported by such evidence that it was impossible to reject it. These two dissertations excited considerable attention: but the opinion that stones had really fallen from the atmosphere was considered as so extraordinary, and so contrary to what we know of the constitution of the air, that most people hesitated, or refused their assent. Meanwhile Mr. Howard took a different method of investigating the subject. He not only collected all the recent and well-authenticated accounts of the fall of stony bodies, and examined the evidence of their truth, but procured specimens of the stones which were said to have fallen in different places, compared them together, and subjected them to a chemical analysis. The result was, that all these stony bodies differ completely from every other known stone; that they all resemble each other; and that they are all composed of the same ingredients. His dissertation on the subject was published in the Philosophical Transactions for 1802. The proofs which this admirable dissertation contains, that the stony bodies in question really fell from the atmosphere, are quite irresistible. Indeed, their external characters and chemical analysis would alone decide the point: for it is quite inconceivable that in India, England, France, Germany, and Italy, in climates and soils exceedingly different from each other, stones should have been pointed out which differed from every other mineral in the countries where they were found, and which exactly resembled one another, provided these had not had the same origin. The chemical analysis of Howard was soon after repeated, and verified, by Vauquelin and Klaproth.

Most of the stones which have fallen from the atmosphere have been preceded by the appearance of luminous bodies or meteors. These meteors burst with an explosion, and then the shower of stones falls to the earth. Sometimes the stones continue luminous till they sink into the earth; but most commonly their luminousness disappears at the time of the explosion. These meteors move in a direction nearly horizontal, and they seem to approach the earth before they explode. The following table, drawn up by Mr. Izarn, exhibits the collection of the best-authenticated instances of the falling of stones, &c. from the atmosphere hitherto observed, together with the time when they fell, and the persons on whose evidence the fact rests.

Substances.	*Places where they fell.*	*Period of their Fall.*	*Testimony.*
Shower of stones	At Rome	Under Tullus Hostilius	Livy
Shower of stones	At Rome	Consuls C. Martius & M. Torquatus	J. Obsequens
Shower of iron	In Lucania	Year before the defeat of Crassus	Pliny
Shower of mercury	In Italy	- - - -	Dion
A very large stone	Near the river Negos, Thrace	Second year of the 78th Olympiad	Pliny
Three large stones	In Thrace	Year before J. C. 452	Ch. of Count Marcellin
Shower of fire	At Quesnoy	January 4th, 1717	Geoffroy le Cadet
Stone of 72 lbs.	Near Larissa, Macedonia	January 1706	Paul Lucas
About 1200 stones—one of 120 lbs. Another of 60 lbs.	Near Padua in Italy	In 1510	Carden, Varcit
Another of 59 lbs.	On Mount Vaiser, Provence	November 27th, 1627	Gassendi
Shower of sand for 15 hours	In the Atlantic	April 6th, 1719	Père la Feuillée
Shower of sulphur	Sodom and Gomorrah	- - - -	Moses
Sulphureous rain	In the duchy of Mansfeld	In 1658	Spangenberg
The same	Copenhagen	In 1646	Olaus Wormius
Shower of sulphur	Brunswick	October 1721	Siegesber
Ditto of a viscid unknown matter	Ireland	In 1695	Muschenbroeck
Two large stones weighing 20 lbs.	Liponas in Bresse	September 1753	Delalande
A stony mass	Niort, Normandy	In 1750	Delalande
A stone of 7½ lbs.	At Luce in Le Maine	September 13th, 1768	Bachelay
A stone	At Aire in Artois	In 1768	Gurson de Boyaval
A stone	In Le Cotentin	In 1768	Morand
Extensive shower of stones	Environs of Agen	July 24th, 1790	St. Amand, Baudin, &c.
About 12 stones	Sienna, Tuscany	July 1794	Earl of Bristol
A large stone of 56 lbs.	Wold-Cottage, Yorkshire	December 13th, 1795	Captain Topham
A stone of about 20 lbs.	Salé, department of the Rhone	March 17th, 1798	Lelievre and De Drée
A stone of 10 lbs.	In Portugal	February 19th, 1796	Southey
Shower of stones	Benares, East Indies	December 19th, 1798	J. Lloyd Williams, Esq.
Shower of stones	At Plann, near Tabor, Bohemia	July 3d, 1753	B. de Born
Mass of iron, 70 cubic feet	America	April 5th, 1800	Philosophical Magazine
Mass of ditto, 14 quintals	Abakank, Siberia	Very old	Pallas, Chladni, &c.
Shower of stones	Barboutan, near Roquefort	July 1789	Darcet, jun. Lomet, &c.
Large stone, 260 lbs.	Ensisheim, Upper Rhine	November 7th, 1492	Butenschoen
Two stones, 200 and 300 lbs.	Near Verona	In 1762	Acad. de Bourd
A stone of 20 lbs.	Sales, near Ville-Franche	March 12th, 1798	De Drée
Several ditto, from 10 to 17 lbs.	Near L'Aigle, Normandy	April 26th, 1803	Fourcroy.

The stony bodies when found are always hot. They commonly bury themselves some depth under ground. Their size differs from a few ounces to several tons. They are usually roundish, and always covered with a black crust. In many cases they smell strongly of sulphur. The black crust, from the analysis of Howard, consists chiefly of oxide of iron.

The outer surface of these stones is rough. When broken, they appear of an ash-grey colour, and of a granular texture like a coarse sandstone. When examined with a microscope, four different substances may be discovered, of which the stone is composed: 1st, A number of spherical bodies, varying in size from a pin's head to a pea, of a greyish-brown colour, opaque, breaking easily in every direction, of a compact texture, capable of scratching glass, and of giving a few feeble sparks with steel. 2d, Fragments of pyrites of an indeterminate shape, of a reddish-yellow colour, granular, and easily reduced to powder. The powder has a black colour. 3d, Grains of iron in the metallic state, scattered like the pyrites through the stone. 4th, The three substances just mentioned are cemented together by a fourth of an earthy consistence, and so soft that all the other substances may be easily separated by the point of a knife or the nail, and the stone itself crumbled to pieces between the fingers. This cement is of a grey colour. The proportion and size of these different constituents vary considerably in different specimens; but all of them bear a striking resemblance to each other. Their specific gravity varies from 3.352 to 4.281.

From the analysis of Howard, which was conducted with much precision and address, and which has been fully confirmed by Vauquelin and Klaproth, we learn, that the black crust consists of a compound of iron and nickel, partly metallic and partly oxydized. The pyrites consist of iron, nickel, and sulphur. The metallic grains consist of iron, combined with about one-third of its weight of nickel, and the yellow globules are composed of silica, magnesia, iron, and nickel. The count Bournon observes, that these globules resemble the chrysolite of Werner, and that their chemical analysis corresponds exactly with Klaproth's analysis of that mineral. The earthy cement consists of the very same substances, and nearly in the same proportions, as the globular substances. But it will be necessary to exhibit a specimen of some of the analyses, as published by the philosophers to whom we are indebted for them. A stone which fell at Benares in India, was analyzed by Howard. The pyrites consisted of,

2.0 sulphur
10.5 iron
1.0 nickel
2.0 earths and foreign bodies.

15.5

The spherical bodies,

50.0 silica
15.0 magnesia
34.0 oxide of iron
2.5 oxide of nickel.

101.5

The earthy cement,

48.0 silica
18.0 magnesia
34.0 oxide of iron
2.5 oxide of nickel.

102.5

A stone which fell in Yorkshire, deprived as much as possible of its metallic particles, gave Mr. Howard from 150 grains,

75 silica
37 magnesia
48 oxide of iron
2 oxide of nickel

162.

The increase of weight was owing to the oxydizement of the metallic bodies.

Stones which fell at Laigle in France in 1803, yielded by the analysis of Vauquelin and Fourcroy,

54 silica
36 oxide of iron
9 magnesia
3 oxide of nickel
2 sulphur
1 lime

105.

The celebrated stone which fell at Ensisheim, in Alsace, in 1492, yielded to the same philosophers,

56.0 silica
30.0 oxide of iron
12.0 magnesia
2.4 nickel
3.5 sulphur
1.4 lime.

105.3

5. The experiments of Howard, thus confirmed by others, and supported by the most respectable historical evidence, having demonstrated that these stony bodies really do fall from the heavens, it was natural to expect that various attempts would be made to account for their appearance. But such is the obscurity of the subject, so little progress have we made in the science of meteorology, that no opinion in the slightest degree probable has hitherto been advanced. It was first supposed that the bodies in question had been thrown out of volcanoes; but the immense distance from all volcanoes at which they have been found, and the absence of all similar stones from volcanic productions, render this opinion untenable. Chladni endeavoured to prove, that the meteors from which they fell were bodies floating in space, unconnected with any planetary system, attracted by the earth in their progress, and kindled by their rapid motion through the atmosphere. But this opinion is not susceptible of any direct evidence, and can scarcely be believed, one would think, even by Dr. Chladni himself. Laplace suggests the probability of their having been thrown off by the volcanoes of the moon: but the meteors which almost always accompany them, and the swiftness of their horizontal motion, militate too strongly against this opinion. The greater number of philosophers consider them, with Mr. King and sir William Hamilton, as concretions actually formed in the atmosphere. This opinion is undoubtedly the most probable of all; but in the present state of our knowledge, it would be absurd to attempt any explanation of the manner in which they are formed. The masses of native iron found in South America, in Siberia, and near Agnam, contain nickel, as has been ascertained by Proust, Howard, and Klaproth, and resemble exactly the iron found in the stones fallen from the atmosphere. We have every reason, therefore, to ascribe to them the same original; and this accordingly is almost the uniform opinion of philosophers. Klaproth has shewn, that real native iron is distinguished from meteoric iron by the absence of nickel.

Upon the whole, we may consider these stony and metallic masses as fragments of fire-balls which have burst in the atmosphere; but the origin and cause of these fire-balls will perhaps for ages baffle all the attempts of philosophers to explain them.

METEOROLOGY, the doctrine of meteors, or the study of the variable phenomena of the atmosphere, in which also is commonly included the art of deducing probable conjectures on the future state of the weather.

The latter branch of this science was successfully cultivated by the antients; and it subsists at this day among those whom necessity, arising from the nature of their occupations, renders diligent in comparing the present appearances of the atmosphere, and circumstances depending on its present state, with the changes which succeed. The aphorisms of Virgil, in his Georgics, are beautiful examples of this kind of skill, and possess philosophical, in an equal degree with poetical, merit.

The atmosphere may be considered in respect of the direction of its currents or winds; of the variations in its gravity or pressure; of the changes in its temperature; of the state of the electricity which it exhibits; and lastly, as to the visible phenomena which are supposed to depend on the foregoing; and the regular notation of which, together with the other indications, will be found the only successful way of prosecuting this study. Since the invention of philosophical instruments, an attention to these has too much superseded the antient, and, singly considered, the more rational, way of deducing prognostics: it has been accordingly left to the ploughman, the mariner, and the fisherman; whose experience being successful without, would undoubtedly be more so with, the aid of instruments.

Winds, though proverbially uncertain in some climates, are yet not without a striking degree of regularity and system, if we consider the whole atmosphere; and there is a part of the world where the wind is so constantly in one quarter, that *windward*, in common speech, stands for eastern, and *leeward* for western. We want only a more extensive set of observations to render exceedingly probable the following hypothesis: That a large portion of the whole atmosphere moves constantly from east to west round the earth, on and near the equator; that this is supplied and impelled by air from the temperate and cold latitudes on each side toward the poles; which again receive, by a superior current, the overflow of the tropical regions, where the air, rarefied by the heat, is constantly rising and tending to lateral diffusion. This opinion, as will appear hereafter, is supported by many facts; and it is certainly in theory a most beautiful provision for that constant internal movement in the mass of the air, without which it could not probably serve the salutary purposes to animal and vegetable life which it does at present. The exceptions both in regular and irregular winds to such an hypothesis may perhaps be accounted for when the superior currents, which interest philosophers alone, and of which we know very little, shall have been more investigated. See Wind.

Variable winds evidently stamp the nature of every climate, and therefore depend upon causes which act with uniformity, notwithstanding all their apparent irregularity. They are all intimately connected with each other, and probably succeed each other in a certain order, though that order has not hitherto been observed. All that can be done at present is, to offer a few unconnected remarks.

Winds appear usually to begin at that point towards which they blow. They must therefore be owing to a rarefaction or displacing of the air in some particular quarter, either by the action of heat or some other cause. This is more particularly the case when the wind blows with violence. Hurricanes are uniformly preceded by a great fall of the barometer; and the wind often flows in every direction towards the place where the barometer stands so low. One would be tempted in this case to suppose the sudden decomposition of a portion of the atmosphere. Strong north-east winds have been repeatedly observed beginning at the quarter towards which they flow. In 1740, Dr. Franklin was prevented from observing an eclipse of the moon at Philadelphia by a north-east storm, which came on about seven o'clock in the evening. He was surprised to find afterwards that it had not come on at Boston till near 11 o'clock: and upon comparing all the accounts which he received from the several colonies of the beginning of this and other storms of the same kind, he found it to be always an hour later the farther north-east for every 100 miles.

"From thence (says he) I formed an idea of the course of the storm, which I will explain by a familiar instance. I suppose a long canal of water stopped by a gate. The water is at rest till the gate is opened; then it begins to move out through the gate, and the water next the gate is first in motion, and moves on towards the gate; and so on successively, till the water at the head of the canal is in motion, which it is last of all. In this case all the water moves indeed towards the gate; but the successive times of beginning the motion are in the contrary way, viz. from the gate back to the head of the canal. Thus, to produce a north-east storm, I suppose some great rarefraction of the air in or near the Gulf of Mexico; the air rising thence has its place supplied by the next more northern, cooler, and therefore denser and heavier air; a successive current is formed, to which our coast and inland mountains give a north-eastern direction."

A similar storm was observed by Dr. Mitchell in 1802. It began at Charlestown on the 21st February, at two o'clock in the afternoon; at Washington, which lies several hundred miles to the north-east, it was not observed till five o'clock; at New York it began at ten in the evening; and at Albany not till day-break of the 22d. Its motion, from this statement, was 1100 miles in 11 hours, or 100 miles in the hour.

A remarkable storm of the same kind, and accompanied by an easterly wind, was observed in Scotland on the 8th of February 1799. It was attended by a very heavy fall of snow, and the motion of the wind was much slower. At Falkirk it began to snow at six in the evening of the 7th; at Edinburgh, about one o'clock in the morning of the 8th; and at Dunbar, at eight o'clock in the morning. It lasted 11 hours, and did not travel above 100 miles during that time.

The north-east wind blows most frequently with us during the spring months; and from the observations made by captain Cook, it appears, that the same wind prevails during the same period in the northern Pacific. Hence it appears, that at that season the cold air from the north of Europe and America flows into the Atlantic and Pacific. Hence the reason of its uncommon coldness, dryness, and density.

It is very common to observe one current of air blowing at the surface of the earth, while a current flows in a contrary direction in the higher strata of the atmosphere. Three such winds have been observed blowing in contrary directions all at the same time. It is affirmed that changes of weather generally begin in the upper strata of the air, the wind which blows there gradually extending itself to the surface of the earth.

With regard to the pressure of the atmosphere, it is every where variable, as appears by the barometer; which indicates to us the weight of a column of air, extending to the top of the atmosphere, and whose base is equal to that of the mercury. At the level of the sea, where the column of air is longest, the mean height of the barometer is thirty inches. This sir George Shuckburgh found to be the case in the Mediterranean and the Channel, in the temperature of 55° and 60°; Mr. Bouguer, on the coast of Peru, in the temperature of 84°; and lord Mulgrave, in latitude 80°. The mean height of the barometer is less, the higher any place is situated above the level of the sea, because the column of air which supports the mercury is the shorter.

Between the tropics the variations of the barometer are exceedingly small; and it is remarkable, that in that part of the world it does not descend above half as much for every 200 feet of elevation as it does beyond the tropics.

As the latitude advances towards the poles, the range of the barometer gradually increases, till at last it amounts to two or three inches. This gradual increase will appear from the following table:

TABLE

Of the Range of the Barometer.

Latitude.	Places.	Range of the Barometer. Greatest.	Annual.
0° 0′	Peru	0.20	—
22 23	Calcutta	0.77	—
33 55	Cape Town	—	0.89
40 55	Naples	1.00	—
51 8	Dover	2.47	1.80
53 23	Liverpool	2.89	1.96
59 56	Petersburgh	3.45	2.77

In North America, however, the range of the barometer is a great deal less than in the corresponding European latitudes. In Virginia, for instance, it never exceeds 1.1.

The range of the barometer is greater at the level of the sea than on the mountains; and in the same degree of latitude, the extent of the range is in the inverse ratio of the height of the place above the level of the sea.

From a table published by Mr. Cotte, in the Journal de Physique, it seems exceedingly probable that the barometer has always a tendency to rise from the morning to the evening; and that this tendency is greatest between two o'clock in the afternoon and nine at night, at which hour the greatest elevation takes place; that the elevation of nine o'clock differs from that of two by $\frac{4}{12}$ths, while that at two differs from the morning elevation only by $\frac{1}{12}$; and that in certain climates the greatest elevation takes place at two o'clock. The following is a part of the table on which these observations are founded, reduced to the English standard.

Places.	Years of observation.	Mean Height of the Barometer. Morning.	Noon.	Evening.	Year.
Arles - -	6	29.9347	29.9347	29.9413	29.9347
Arras - -	6	29.6683	29.6683	29.6832	29.6758

Troyes - -	10	29.6885	29.6979	29.6885	29.6885

The range of the barometer is greater in winter than in summer. Thus at York the mean range of the barometer, during October, November, December, January, February, March, of the year 1774, was 1.42, and for the six summer months, 1.016.

It is probable that the variations of the barometer, as well as those of the thermometer, are susceptible of what we may term a local character for each tract or country differing in climate. This will be most readily discovered by the following mode of investigation: Prepare a sheet of paper ruled in squares with pale ink; the horizontal lines agreeing with the inches and decimal divisions of the scale of the barometer; the perpendicular, which may be about twice as distant, representing divisions of time. It will be convenient to consider each line as denoting midnight, and to mark the days of the month at the top of the columns thus defined. On this scale let the several notations of any register of the barometer be set down by means of a dot for each, placed in the part of the scale where it may point out the time and the elevation. The desired number of notations thus made, a curve may be drawn through the series of dots, which will represent at one view the course of the barometer for the time. It will be found, on comparing a number of these curves, that they characterize, in a certain degree, not only the latitude and season, but the locality of the observations. So that although the most obvious resemblances may be traced in different years of the same register, yet the general appearance of registers from different climates, will be found to differ in all respects. In this way may be seen at one view both the correspondence between the latitude or elevation above the sea of any place, and the range at that place; and the coincidence between the movements of the barometer, and the other phenomena of the weather. It is obvious that the same mode, and even the same scale, may be made to serve for temperature also, by marking degrees upon the horizontal lines, and changing the appearance of the line representing temperature, so as to make it readily distinguishable from the other curve. There is a correspondence in this climate between the two instruments, which will thus often become conspicuous. It consists in an elevation of temperature after a rise of the barometer, and vice versa: the exceptions to this occur chiefly at the setting in of frost, and when it rains with the wind from the eastward. But the most remarkable circumstance which has been thus brought to light is, an influence which the sun and moon exercise over the atmosphere in respect to its pressure; and which is detailed in a series of observations, accompanied with a chart of this kind, for the year 1798, in the Philosophical Magazine, vol. vii. p. 355.

The effect of this is, a tendency in the atmosphere to gain weight while the moon is passing to either quarter, and vice versa to lose it during the approach of full or new moon. The actual change which on a mean of ten years is found always to take place at London, amounts only to two-tenths of an inch in the barometer, which thus occurs twice in each moon. The apparent influence is often much greater for a considerable time together. The specimen of the register alluded to, which is given Plate Meteorology, will elucidate the whole of the foregoing observations.

There is something in these movements of the atmosphere very much resembling the waves producible in dense fluids. Thus a sudden and great depression in the barometer is followed by an equally sudden rise, which is often carried beyond the point from which the original movement commenced. After a continued gradual rise on the other hand, there usually occurs a similar depression. Except on the eve of great storms, the rising movement is however the more rapid of the two. The undulations which are to be found in the curve corresponding to the intervals between the phases of the moon, often comprehend in their sweep some smaller ones, which appear to be due to occasional and less extensive causes.

It happens also from some principle of the kind above stated, that these movements, which in fair and moderate weather proceed with considerable regularity, on being disturbed by storms, a.e not resumed suddenly but by degrees, and the interruption is perceptible for a considerable space afterwards.

In long periods of wet weather, the barometer usually keeps about the mean altitude, rising and falling through a short space with little regularity.

In serene and settled weather it is generally high; and low in calm weather, when the air is inclined to rain; it sinks on high winds, rises highest on easterly and northerly winds, and sinks when the wind blows from the south. At Calcutta, it is always highest when the wind blows from the north-west and north, and lowest when it blows from the south-east.

Such are the phenomena respecting the variations of the barometer, as far as they can be reduced under general heads. Various attempts have been made to explain them, but hitherto without any great degree of success. The theory of Mr. Kirwan appears by far the most plausible, though it is not sufficient to explain all the facts. The following observations may be considered as a kind of abstract of his theory, except in one or two instances.

It is evident, that the density of the atmosphere is least at the equator, and greatest at the poles; for at the equator, the centrifugal force, the distance from the centre of the earth, and the heat, all of which tend to diminish the density of the air, are at their maximum, while at the pole they are at their minimum. The mean height of the barometer at the level of the sea, all over the globe, is 30 inches; the weight of the atmosphere, therefore, is the same all over the globe. The weight of the atmosphere depends on its density and height: where the density of the atmosphere is greatest, its height must be least; and, on the contrary, where its density is least, its height must be the greatest. The height of the atmosphere, therefore, must be greatest at the equator, and least at the poles; and it must decrease gradually between the equator and the poles: so that its upper surface will resemble two inclined planes, meeting above the equator in their highest part.

During summer, when the sun is in our hemisphere, the mean heat between the equator and the pole does not differ so much as in winter. Indeed, the heat of northern countries at that time equals the heat of the torrid zone: thus in Russia, during July and August, the thermometer rises to 85°. Hence the rarity of the atmosphere at the pole, and consequently its height, will be increased. The upper surface of the atmosphere, therefore, in the northern hemisphere, will be less inclined, while that of the southern hemisphere, from contrary causes, will be much more inclined. The very reverse will take place during our winter.

The density of the atmosphere depends in a great measure on the pressure of the superincumbent column; and therefore decreases, according to the height, as the pressure of the superincumbent column constantly decreases. But the density of the atmosphere in the torrid zone will not decrease so fast as in the temperate and frigid zones; because its column is longer, and because there is a greater proportion of air in the higher part of this column. This accounts for the observation of Mr. Cassan, that the barometer only sinks half as much for every 200 feet of elevation in the torrid as in the temperate zones. The density of the atmosphere at the equator, therefore, though at the surface of the earth it is less, must at a certain height equal, and at a still greater surpass, the density of the atmosphere in the temperate zones and at the poles.

A current of air is constantly ascending at the equator, and part of it at least reaches and continues in the higher parts of the atmosphere. From the fluidity of air, it is evident, that it cannot accumulate above the equator, but must roll down the inclined plane which the upper surface of the atmosphere assumes towards the poles. As the surface of the atmosphere of the northern is more inclined during our winter than that of the southern hemisphere, a greater quantity of the equatorial current of air must flow over upon the northern than upon the southern atmosphere; so that the quantity of our atmosphere will be greater during winter than that of the southern hemisphere: but during summer the very reverse will take place. Hence the greatest mercurial heights take place during winter, and the range of the barometer is less in summer than in winter.

As the heat in the torrid zone never differs much, the density, and consequently the height, of the atmosphere, will not vary much. Hence the range of the barometer within the tropics is comparatively small; and it increases gradually as we approach the poles, because the difference of the temperature, and consequently of the density, of the atmosphere, increases with the latitude.

The diurnal elevation of the barometer in the torrid zone corresponding to the tides, observed by Mr. Cassan and others, must be owing to the influence of the moon on the atmosphere. This influence, notwithstanding the ingenious attempts of D'Alembert and several other philosophers, seems altogether inadequate to account for the various phenomena of the winds. It is not so easy to account for the tendency which the barometer has to rise as the day advances, which seems to be established by Mr. Cotte's table. Perhaps it may be accounted for by the additional quantity of vapour added to the atmosphere, which, by increasing the quantity of the atmosphere, may possibly be adequate to produce the effect.

The falls of the barometer which precede, and the oscillations which accompany, violent storms and hurricanes, shew us, that these phenomena are produced by very great rarefactions, or perhaps destruction of air, in particular parts of the atmosphere. The falls of the barometer, too, that accompany winds, proceed from the same cause.

That the temperature of the air varies considerably, not only in different climates and in different seasons, but even in the same place and in the same season, must be obvious to the most careless observer. This perpetual variation cannot be ascribed to the direct heat of the sun; for the rays of that luminary seem to produce no effect whatever upon air, though ever so much concentrated; but they warm the surface of the earth, which communicates its heat to the surrounding atmosphere. Hence it happens, that the temperature of the air is highest in those places which are so situated as to be most warmed by the sun's rays, and that it varies in every region with the season of the year. Hence too the reason why it diminishes according to the height of the air above the surface of the earth. That portion of the earth which lies at the equator, is exposed to the most perpendicular rays of the sun. Of course it is hottest, and the heat of the earth diminishes gradually from the equator to the poles. The temperature of the air must follow the same order. The air, then, is hottest over the equator; and its temperature gradually diminishes from the equator to the poles, where it is coldest of all. It it hottest at the surface; and it becomes gradually colder, according to its height above that surface. Let us examine the nature of these two diminishing progressions of temperature.

1. Though the temperature of the air is highest at the equator, and gradually sinks as it approaches the pole, yet as in every place the temperature of the air is constantly varying with the season of the year, we cannot form any precise notion of the progression, without taking the temperature in every degree of latitude for every day of the year, and forming from each a mean temperature for the whole year; which is done by adding together the whole observations, and dividing by their number. The quotient gives the mean temperature for the year. The diminution from the pole to the equator takes place in arithmetical progression; or, to speak more properly, the annual temperatures of all the latitudes are arithmetical means between the mean annual temperature of the equator and the pole. This was first discovered by Mr. Mayer; and by means of an equation which he founded on it, but rendered considerably plainer and simpler, Mr. Kirwan has calculated the mean annual temperature of every degree of latitude between the equator and the pole. He proceeded on the following principle: Let the mean annual heat at the equator be m, and at the pole $m - n$; put φ for any other latitude; the mean annual temperature of that latitude will be $m - n \times \sin. \varphi^2$. If therefore the temperature of any two latitudes is known, the value of m and n may be found. Now the temperature of north latitude 40° has been found by the best observations to be 62.1°, and that of latitude 50°, 52.9°. The square of the sine of 40° is nearly 0.419, and the square of the sine of 50° is nearly 0.586. Therefore,

$m - 0.41\ n = 62.1$, and

$m - 0.58\ n = 52.9$; therefore,

$62.1 + 0.41\ n = 52.9 + 0.58\ n$; as each of them, from the two first equations, is equal to m. From this last equation the value of n is found to be 53 nearly; and m is nearly equal to 84. The mean temperature of the equator, therefore, is 84°, and that of the pole 31°. To find the mean temperature for every other latitude, we have only to find 88 arithmetical means between 84 and 31. In this manner Mr. Kirwan calculated the following table:

TABLE

Of the Mean Annual Temperature of the Standard Situation in every Latitude.

Lat.	Temper.	Lat.	Temper.	Lat.	Temper.
90	31.	71	36.6	52	51.1
89	31.04	70	37.2	51	52.4
88	31.10	69	37.8	50	52.9
87	31.14	68	38.4	49	53.8
86	31.2	67	39.1	48	54.7
85	31.4	66	39.7	47	55.6
84	31.5	65	40.4	46	56.4
83	31.7	64	41.2	45	57.5
82	32.	63	41.9	44	58.4
81	32.2	62	42.7	43	59.4
80	32.6	61	43.5	42	60.3
79	32.9	60	44.3	41	61.2
78	33.2	59	45.09	40	62.
77	33.7	58	45.8	39	63.
76	34.1	57	46.7	38	63.9
75	34.5	56	47.5	37	64.8
74	35.	55	48.4	36	65.7
73	35.5	54	49.2	35	66.6
72	36.	53	50.2	34	67.4

Lat.	Temper.	Lat.	Temper.	Lat.	Temper.
33	68.3	23	75.9	13	81.3
32	69.1	22	76.5	12	81.7
31	69.9	21	77.2	11	82.
30	70.7	20	77.8	10	82.3
29	71.5	19	78.3	9	82.7
28	72.3	18	78.9	8	82.9
27	72.8	17	79.4	7	83.2
26	73.8	16	79.9	6	83.4
25	74.5	15	80.4	5	83.6
24	75.4	14	80.8	0	84.

This table, however, only answers for the temperature of the atmosphere of the ocean. It was calculated for that part of the Atlantic Ocean which lies between the 80th degree of northern and the 45th of southern latitude, and extends westward as far as the Gulf-stream, and to within a few leagues of the coast of America; and for all that part of the Pacific Ocean reaching from latitude 45° north to latitude 40° south, from the 20th to the 275th degree of longitude east of London. This part of the ocean Mr. Kirwan calls the standard; the rest of the ocean is subject to anomalies which will be afterwards mentioned.

Mr. Kirwan has also calculated the mean monthly temperature of the standard ocean. The principles on which he went were these: The mean temperature of April seems to approach very nearly to the mean annual temperature; and as far as heat depends on the action of the solar rays, the mean heat of every month is as the mean altitude of the sun, or rather as the sine of the sun's altitude. The mean heat of April, therefore, and the sine of the sun's altitude, being given, the mean heat of May is found in this manner: As the sine of the sun's mean altitude in April, is to the mean heat of April, so is the sine of the sun's mean altitude in May, to the mean heat of May. In the same manner the mean heats of June, July, and August, are found; but the rule would give the temperature of the succeeding months too low, because it does not take in the heat derived from the earth, which possesses a degree of heat nearly equal to the mean annual temperature. The real temperature of these months, therefore, must be looked upon as an arithmetical mean between the astronomical and terrestrial heats. Thus, in latitude 51°, the astronomical heat of the month of September is 44.6°, and the mean annual heat is 52.4°; therefore the real heat of this month should be $\frac{44.6 + 52.4}{2} = 48.5$. Mr. Kirwan, however, after going through a tedious calculation, found the results to agree so ill with observations, that he drew up the following table, partly from principles, and partly by studying a variety of sea journals:

TABLE of the Monthly Mean Temperature of the Standard from Lat. 80° to Lat. 10°.

From this table it appears, that January is the coldest month in every latitude, and that July is the warmest month in all latitudes above 48°. In lower latitudes, August is generally warmest. The difference between the hottest and coldest months increases in proportion to the distance from the equator. Every habitable latitude enjoys a mean heat of 60° for at least two months; this heat seems necessary for the production of corn. Within ten degrees of the poles, the temperatures differ very little; neither do they differ much within ten degrees of the equator: the temperatures of different years differ very little near the equator; but they differ more and more as the latitudes approach the poles.

2. That the temperature of the atmosphere gradually diminishes, according to its height above the level of the sea, is well known. Thus the late Dr. Hutton, of Edinburgh, found, that a thermometer, kept on the top of Arthur's-seat, usually stood three degrees lower than a thermometer kept at the bottom of it. Hence, then, a height of 800 feet occasioned 3° of diminution of temperature. On the summit of Pinchinca, the thermometer stood at 30°, as observed by Bouguer; while at the level of the sea, in the same latitude, it stood at 84°. Here a height of 15564 feet occasioned a diminution of temperature, amounting to 54°. But though there can be no doubt of the gradual diminution of temperature, according to the height, it is by no means easy to determine the rate of diminution. Euler supposes it to be in a harmonic progression; but this opinion is contradicted by observations. Saussure supposes, that in temperate climates the diminution of temperature amounts to 1° for every 287 feet of elevation. But Mr. Kirwan has shewn that no such rule holds, and that the rate of diminution varies with the temperature at the surface of the earth. We are indebted to this philosopher for a very ingenious method of determining the rate of diminution in every particular case, supposing the temperature at the surface of the earth known.

Since the temperature of the atmosphere is constantly diminishing as we ascend above the level of the sea, it is obvious, that at a certain height we arrive at the region of perpetual congelation. This region varies in height according to the latitude of the place; it is highest at the equator, and descends gradually nearer the earth as we approach the poles. It varies also according to the season, being highest in summer, and lowest in winter. M. Bouguer found the cold on the top of Pinchinca, one of the Andes, to extend from seven to nine degrees below the freezing-point every morning immediately before sunrise. He concluded, therefore, that the mean height of the term of congelation (the place where it freezes during some part of the day all the year round) between the tropics was 15,577 feet above the level of the sea; but in latitude 28° he placed it in summer at the height of 13,440 feet. Now, if we take the difference between the temperature of the equator and the freezing-point, it is evident that it will bear the same proportion to the term of congelation at the equator, that the difference between the mean temperature of any other degree of latitude and the freezing-point bears to the term of congelation in that latitude. Thus the mean heat of the equator being 84°, the difference between it and 32 is 52; the mean heat of latitude 28° is 72.3°; the difference between which and 32 is 40.3: then 52 : 15577 :: 40.3 : 12072. In this manner Mr. Kirwan calculated the following table:

Lat.			Mean height of the term of congelation. *Feet.*
0	-	-	15577
5	-	-	15457
10	-	-	15067
15	-	-	14498
20	-	-	13719
25	-	-	13030
30	-	-	11592
35	-	-	10664
40	-	-	9016
45	-	-	7658
50	-	-	6260
55	-	-	4912
60	-	-	3684
65	-	-	2516
70	-	-	1557
75	-	-	748
80	-	-	120

Beyond this height, which has been called the lower term of congelation, and which must vary with the season and other circumstances, Mr. Bouguer has distinguished another, which he called the upper term of congelation; that is, the point above which no visible vapour ascends. Mr. Kirwan considers this line as much less liable to vary during the summer months than the lower term of congelation, and therefore has made choice of it to determine the rate of the diminution of heat, as we ascend in the atmosphere. Bouguer determined the height of this term in a single case, and Kirwan has calculated the following table of its height for every degree of latitude in the northern hemisphere:

TABLE

Of the Height of the Upper Line of Congelation in the different Latitudes of the Northern Hemisphere.

N. Lat.	Feet.	N. Lat.	Feet.	N. Lat.	Feet.

The following rule of Mr. Kirwan will enable us to ascertain the temperature at any required height, provided we know the temperature at the surface of the earth.

Let the observed temperature at the surface of the earth be $= m$, the height given $= b$, and the height of the upper term of congelation for the given latitude be $= t$; then $\frac{m - 32}{\frac{t}{100} - 1} =$ the diminution of temperature for every hundred feet of elevation; or it is the common difference of the terms of the progression required. Let this common difference thus found be denoted by c; then $c \times \frac{b}{100}$ gives us the whole diminution of temperature from the surface of the earth to the given height. Let this diminution be denoted by d, then $m - d$ is obviously the temperature required. An example will make this rule sufficiently obvious. In latitude 56°, the heat below being 54°, required the temperature of the air at the height of 803 feet?

Here $m = 54$, $t = 5533$, $\frac{m - 32}{\frac{t}{100} - 1} = \frac{22}{54.33} = 0.404 = c$, and $c \times \frac{b}{100} = 0.404 \times 8.03 = 3.24 = d$, and $m - d = 54 - 3.24 = 50.75$. Here we see that the temperature of the air 808 feet above the surface of the earth is 50°. 75.

From this method of estimating the diminution of temperature, which agrees remarkably well with observation, we see that the heat diminishes in an arithmetical progression. Hence it follows, that the heat of the air at a distance from the earth is not owing to the ascent of hot strata of air from the surface of the earth, but to the conducting power of the air.

3. This rule, however, applies only to the temperature of the air during the summer months of the year. In winter the upper strata of the atmosphere are often warmer than the lower. Thus, on the 31st of January, 1776, the thermometer on the summit of Arthur's-seat stood six degrees higher than a thermometer at Hawkhill, which is 684 feet lower. Mr. Kirwan considers this superior heat, almost uniformly obs rved during winter, as owing to a current of warm air from the equator, which rolls towards the north pole during our winter.

4. Such, then, in general is the method of finding the mean annual temperature over the globe. There are, however, several exceptions to these general rules, which come now to be mentioned.

That part of the Pacific Ocean which lies between north latitudes 52° and 66°, is no broader at its northern extremity than 42 miles, and at its southern extremity than 1300 miles: it is reasonable to suppose, therefore, that its temperature will be considerably influenced by the surrounding land, which consists of ranges of mountains covered a great part of the year with snow; and there are besides a great many high, and consequently cold, islands scattered through it. For these reasons Mr. Kirwan concludes, that its temperature is at least four or five degrees below the standard. But we are not yet furnished with a sufficient number of observations to determine this with accuracy.

It is the general opinion, that the southern hemisphere, beyond the 40th degree of latitude, is considerably colder than the corresponding parts of the northern hemisphere. Mr. Kirwan has shewn that this holds with respect to the summer of the southern hemisphere, but that the winter in the same latitudes is milder than in the northern hemisphere.

Small seas surrounded with land, at least in temperate and cold climates, are generally warmer in summer and colder in winter than the standard ocean, because they are a good deal influenced by the temperature of the land. The gulf of Bothnia, for instance, is for the most part frozen in winter; but in summer it is sometimes heated to 70°, a degree of heat never to be found in the opposite part of the Atlantic. The German Sea is above three degrees colder in winter, and five degrees warmer in summer, than the Atlantic. The Mediterranean Sea is, for the greater part of its extent, warmer both in summer and winter than the Atlantic, which therefore flows into it. The Black Sea is colder than the Mediterranean, and flows into it.

The eastern parts of North America are much colder than the opposite coast of Europe, and fall short of the standard by about 10° or 12°, as appears from American meteorological tables. The causes of this remarkable difference are many. The highest part of North America lies between the 40th and 50th degree of north latitude, and the 100th and 110th degree of longitude west from London; for there the greatest rivers originate. The very height, therefore, makes this spot colder than it otherwise would be. It is covered with immense forests, and abounds with large swamps and morasses, which render it incapable of receiving any great degree of heat; so that the rigour of winter is much less tempered by the heat of the earth than in the old continent. To the east lie a number of very large lakes; and farther north, Hudson's-bay; about 50 miles on the south of which there is a range of mountains, which prevent its receiving any heat from that quarter. This bay is bounded on the east by the mountainous country of Labrador, and by a number of islands. Hence the coldness of the north-west winds, and the lowness of the temperature. But as the cultivated parts of North America are now much warmer than formerly, there is reason to expect that the climate will become still milder when the country is better cleared of woods, though perhaps it will never equal the temperature of the old continent.

Islands are warmer than continents in the same degree of latitude; and countries lying to the windward of extensive mountains or forests are warmer than those lying to the leeward. Stones or sand have a less capacity for heat than earth has, which is always somewhat moist; they heat or cool, therefore, more rapidly and to a greater degree. Hence the violent heat of Arabia and Africa, and the intense cold of Terra del Fuego. Living vegetables alter their temperature very slowly, but their evaporation is great; and if they are tall and close, as in forests, they exclude the sun's rays from the earth, and shelter the winter snow from the wind and the sun. Woody countries, therefore, are much colder than those which are cultivated.

Air is one of those bodies which have received the name of electric, because they are capable of being positively or negatively charged with electric matter. It not only contains that portion of electricity which seems necessary to the constitution of all terrestrial bodies, but it is liable also to be charged negatively or positively when electricity is abstracted or introduced by means of conducting bodies. These different states must occasion a variety of phenomena, and in all probability contribute very considerably to the various combinations and decompositions which are continually going on in air. The electrical state of the atmosphere, then, is a point of considerable importance, and has with great propriety occupied the attention of philosophers ever since Dr. Franklin demonstrated that thunder is occasioned by the agency of electricity.

1. The most complete set of observations on the electricity of the atmosphere were made by professor Beccaria of Turin. He found the air almost always positively electrical, especially in the day-time and in dry weather. When dark or wet weather clears up, the electricity is always negative. Low thick fogs rising into dry air carry up a great deal of electric matter.

2. In the morning, when the hygrometer indicates dryness equal to that of the preceding day, positive electricity obtains even before sunrise. As the sun gets up, this electricity increases more remarkably if the dryness increases. It diminishes in the evening.

3. The mid-day electricity of days equally dry is proportional to the heat.

4. Winds always lessen the electricity of a clear day, especially if damp.

5. For the most part, when there is a clear sky with little wind, a considerable electricity arises after sunset at dew-falling.

6. Considerable light has been thrown upon the sources of atmospherical electricity by the experiments of Saussure and other philosophers. Air is not only electrified by friction, like other electric bodies, but the state of its electricity is changed by various chemical operations which often go on in the atmosphere. Evaporation seems in all cases to convey electric matter into the atmosphere. On the other hand, when steam is condensed into water, the air becomes negatively electric.

Farther, Mr. Canton has ascertained that dry air, when heated, becomes negatively electric, and positive when cooled, even when it is not permitted to expand or contract: and the expansion and contraction of air also occasion changes in its electric state.

Thus there are four sources of atmospheric electricity known: 1. Friction; 2. Evaporation; 3. Heat and cold; 4. Expansion and contraction: not to mention the electricity evolved by the melting, freezing, solution, &c. of various bodies in contact with air.

7. As air is an electric, the matter of electricity, when accumulated in any particular strata, will not immediately make its way to the neighbouring strata, but will induce in them changes similar to what is induced upon plates of glass or similar bodies piled upon each other. Therefore, if a stratum of air is electrified positively, the stratum immediately above it will be negative, the stratum above that positive, and so on. Suppose now that an imperfect conductor was to come into contact with each of these strata: we know from the principles of electricity that the equilibrium would be restored, and that this would be attended with a loud noise, and with a flash of light. Clouds are imperfect conductors: if a cloud, therefore, comes into contact with two such strata, a thunderclap will follow. If a positive stratum is situated near the earth, the intervention of a cloud will, by serving as a stepping-stone, bring the stratum within the striking distance, and a thunderclap will be heard while the electrical fluid is discharging itself into the earth. If the stratum is negative, the contrary effects will take place. It does not appear, however, that thunder is often occasioned by a discharge of electric matter from the earth into the atmosphere. The accidents, most of them at least, which were formerly ascribed to this cause, are now much more satisfactorily accounted for by lord Stanhope's theory of the returning stroke. The discharge from the clouds directly into

the earth is also probably less frequent than from cloud to cloud.

The far greater part of the visible phenomena of the atmosphere are due to the water which, being raised by evaporation, is transported from place to place in vapour, and which, physically speaking, is a proper component part of the air. When by any means a portion of this is deprived of its constituent caloric, it reappears in minute drops, which are at first uniformly diffused, and lessen the transparency of the air in proportion to their abundance. By the report of those who have ascended the highest mountains, or performed aerostatic voyages, there is usually a sufficient quantity of this diffused water, especially towards evening, to become visible from above as a sea of haze. It should seem that this is, in fact, the veil which, being drawn over the sable of the sky, converts it to a blue of various degrees of intensity; or at least that it shares with the transparent air in this effect.

The next stage is dew, or rather haze, for the latter term seems more appropriate to the appearance of dew while it is falling. Here the drops have so far become collected as to form an aggregate faintly defined in the air. To this succeed various definite aggregates, under the general term cloud. Out of the latter are formed rain, snow, and hail, by which the product of evaporation is finally restored to the earth. The excess for any given time, of the falling water over that which is evaporated, passes off by the springs and rivers to that grand reservoir which forms the far greater part of the surface of the globe.

Tracts of forest, especially if mountainous, invite the rain, and protect the springs; while the accumulated heat on cultivated plains often causes the clouds to pass over them, or to be dissipated. Clearing of land and culture, therefore, tend to lessen the rain and the rivers; but it is for the interest of agriculture to leave a certain quantity of timber growing, especially in springy lands, and to repair the waste of it by planting; for it is not impossible, that in a series of ages, the axe and the plough too freely applied might convert a tract of fruitful country into one little better than an African desert.

The mean annual quantity of rain is greatest at the equator, and decreases gradually as we approach the poles. Thus at

Granada, Antilles,	12° N. lat.	it is	126 inches
Cape François, St. Domingo	19° 46′	- -	120
Calcutta - - -	22 23	- -	81
Rome - - - -	41 54	- -	39
England - - -	33	- -	32
Petersburgh - -	59 16	- -	16.

On the contrary, the number of rainy days is smallest at the equator, and increases in proportion to the distance from it. From north latitude 12° to 43°, the mean number of rainy days is 78; from 43° to 46° the mean number is 103; from 46° to 50° it is 134; from 51° to 60°, 161.

The number of rainy days is often greater in winter than in summer; but the quantity of rain is greater in summer than in winter. At Petersburgh the number of rainy or snowy days during winter is 84, and the quantity which falls is only about five inches; during summer the number of rainy days is nearly the same, but the quantity which falls is about 11 inches.

More rain falls in mountainous countries than in plains. Among the Andes it is said to rain almost perpetually; while in Egypt it hardly ever rains at all. If a rain-gauge is placed on the ground, and another at some height perpendicularly above it, more rain will be collected into the lower than into the higher; a proof that the quantity of rain increases as it descends, owing perhaps to the drops attracting vapour during their passage through the lower strata of the atmosphere where the greatest quantity resides. This, however, is not always the case, as Mr. Copland of Dumfries discovered in the course of his experiments. He observed also, that when the quantity of rain collected into the lower gauge was greatest, the rain commonly continued for some time; and that the greatest quantity was collected in the higher gauge only either at the end of great rains, or during rains which did not last long. These observations are important; and may, if followed out, give us new knowledge of the causes of rain. They seem to show, that during rain the atmosphere is somehow or other brought into a state which induces it to part with its moisture; and that the rain continues as long as this state continues. Were a sufficient number of observations made on this subject in different places, and was the atmosphere carefully analysed during dry weather, during rain, and immediately after rain, we might soon perhaps discover the true theory of rain.

Rain falls in all seasons of the year, at all times of the day, and during the night as well as the day; though, according to M. Toaldo, a greater quantity falls during the day than the night. The cause of rain then, whatever it may be, must be something which operates at all times and seasons. Rain falls also during the continuance of every wind, but oftenest when the wind blows from the south. Falls of rain often happen likewise during perfect calms.

It appears from a paper published by M. Cotte in the Journal de Physique for Oct. 1791, containing the mean quantity of rain falling at 147 places situated between north lat. 11° and 60°, deduced from tables kept at these places, that the mean annual quantity of rain falling in all these places is 34.7 inches. Let us suppose then (which cannot be very far from the truth) that the mean annual quantity of rain for the whole globe is thirty-four inches. The superficies of the globe consists of 170,981,012 square miles, or 686,401,498,471,475,200, square inches. The quantity of rain therefore falling annually will amount to 23,337,650,812,030,156,800 cubic inches, or somewhat more than 91,751 cubic miles of water.

The dry land amounts to 52,745,253 square miles; the quantity of rain falling on it annually therefore will amount to 30,960 cubic miles. The quantity of water running annually into the sea is 13,140 cubic miles; a quantity of water equal to which must be supplied by evaporation from the sea, otherwise the land would soon be completely drained of its moisture.

The quantity of rain falling annually in Great Britain may be seen from the following table: which is probably the most extensive of the kind; and as accurate as the use of instruments, not constructed by one person and adjusted to a common standard, will allow. It is mostly compiled from the Transactions of different learned societies.

As the places subject to much rain predominate considerably in this list, it will probably be nearer the truth, if we take the mean annual rain in England and Wales at a quantity not exceeding 32 inches.

In this country it generally rains less in March than in November, in the proportion at a medium of 7 to 12. It generally rains less in April than October in the proportion of 1 to 2 nearly at a medium. It generally rains less in May than September; the chances that it does so are at least 4 to 3: but when it rains plentifully in May (as 1.8 inches or more), it generally rains but little in September; and when it rains one inch or less in May, it rains plentifully in September.

Snow is evidently formed by a process of regular crystallisation among minute frozen particles of water floating in the air. It is remarkable, that previous to, and during, the fall of snow in quantity, the temperature continues about 32°. It should seem that the evolution of the constituent caloric of the water produces the same effect when ice is formed in the atmosphere, as when it is formed in water. The structure of a crystal of snow demonstrates that a drop of rain is also formed by the union of a great number of smaller drops. When these come together in the act of freezing, and suddenly, they form a nucleus of white spongy ice, which, by its extreme coldness, becoming incrusted with clear ice from the water it collects in its descent, constitutes hail as we usually see it. Sometimes, however, the nucleus falls unincrusted, which is a prognostic of sharp frosts. Hail has been likewise observed perfectly transparent, and having the form of an oblate spheroid, showing that it consisted of drops which had been frozen entire in falling with a rotatory motion.

The forms assumed by the suspended water in the interval between the first precipitation and the descent of rain, afford a copious field of observation. These are not, as might be hastily supposed, the sport of winds, changing with every movement of the containing medium. Indeed the atmosphere, at the height where clouds usually appear, is undisturbed by the various obstacles which throw it into contending streams and eddies near the surface of the earth, and flows in a more direct and even current. Accordingly, the particles of water which it contains are allowed to assume a certain arrangement; and constitute a form, which is often equally well defined at a distance with that of solids, although, were we to penetrate it, we should perceive only the grey mist.

These forms have lately been discovered to be subject to certain laws in their production, their action on each other, and their resolution into rain. The visible course of these has been traced and described; and the antient mode of drawing prognostics seems in consequence likely to be restored, with the advantage of a nomenclature, by which the learned may reason on a subject hitherto, for want of terms, in a manner incommunicable, and confined to the adepts of experience. Before the nomenclature, it will be proper to exhibit the general principles on which its author proceeds in his explanation of the facts.

Evaporation is not a process of solution in air, neither is it probable that the water is decomposed by it. It is the same procession in the great scale of nature, as in a small quantity of water placed over the fire. Vapour is formed and diffused in all directions from its source with a force proportioned to the temperature of the water, and subject to the opposing force of the vapour already in the air.

The vapour thus emitted may be decomposed in different ways; as, 1. Immediately on its passing into the atmosphere, producing a fog or mist. 2. After having mounted through the warm air, near the earth, on its arrival in a higher and colder region, in which case dense clouds are there formed. 3. After having been uniformly mixed with the mass of the atmosphere, and perhaps travelled with it to a great distance from its source; in this case it either falls in dew, or is collected into sheets or horizontal beds during a slower subsidence; or lastly, it becomes a conductor to the electricity, if the equilibrium of the latter is disturbed; and indicates by its arrangement in threads, the usual effects of that fluid on light bodies.

In every case, the caloric which constituted the vapour decomposed, appears to pass into the atmosphere, which hence becomes often sensibly warmer just before rain; and on the other hand, the evaporation of the water suspended in the air, robs it of so much as to become sensible to our feelings in its comparative coldness.

The predisposing causes of these changes near the earth are probably to be found in the state of the superior currents, which undoubtedly both impart and carry off great quantities of vapour; but this part of the subject is at present imperfectly provided with such observations as might serve for data to our reasoning.

There are three simple and distinct modifications, in any one of which the aggregate of minute drops, called a cloud, may be formed, increase to its greatest extent, and finally decrease and disappear.

By modification is to be understood simply the structure or manner of aggregation, not the precise form or magnitude, which indeed varies every moment in most clouds. The principal modifications are commonly as distinguishable from each other as a tree from a hill, or the latter from a lake; although clouds in the same modification, considered with respect to each other, have often only the common resemblances which exist among trees, hills, or lakes, taken generally.

The same aggregate, which has been formed in one modification, upon a change in the attendant circumstances may pass into another.

Or it may continue a considerable time in an intermediate state, partaking of the characters of two modifications; and it may also disappear in this stage, or return to the first modification. Lastly, aggregates, separately formed in different modifications, may unite and pass into one, exhibiting different characters in different parts; or a portion of a simple aggregate may pass into another modification, without separating from the remainder of the mass. Hence, together with the simple, it becomes necessary to admit intermediate and compound modifications, and to impose names on such of them as are worthy of notice.

The simple modifications are thus named and defined: (See Plate Meteorology.)

1. *Cirrus.* Def. Nubes cirrata, tenuissima, quæ undique crescat.

Parallel, flexuous, or diverging fibres, extensible in any or in all directions.

2. *Cumulus.* Def. Nubes cumulata, densa, sursum crescens.

Convex or conical heaps, increasing upward from a horizontal base.

3. *Stratus.* Def. Nubes strata, aquæ modo expansa, deorsum crescens.

A widely extended, continuous, horizontal sheet, increasing from below.

The intermediate modifications which require to be noticed are:

4. *Cirro-cumulus.* Def. Nubeculæ densiores, subrotundæ, et quasi in agmine appositæ.

Small, well defined, roundish masses, in close horizontal arrangement.

5. *Cirro-stratus.* Def. Nubes extenuata, subconcava vel undulata. Nubeculæ hujusmodi appositæ.

Horizontal or slightly inclined masses, attenuated towards a part or the whole of their circumference, concave downward; or undulated, separate, or in groups, consisting of small clounds, having these characters.

The compound modifications are:

6. *Cumulo-stratus.* Def. Nubes densa, basim cumuli cum structura patente exhibens.

A dense cloud with the base of the cumulus, but in its upper part extended into a broad flat structure.

7. *Cumulo-cirro-stratus, vel nimbus.* Def. Nubes vel nubium congeries pluviam effundens.

The rain cloud. A cloud, or system of clouds, from which rain is falling. It is a horizontal sheet, above which the cirrus spreads, while the cumulus enters it laterally, and from beneath.

Of the cirrus.

Clouds in this modification have the least density, the greatest elevation, and the greatest variety of extent and direction. They are the earliest appearance after serene weather. They are first indicated by a few threads pencilled, as it were, on the sky. These increase in length, and new ones are in the mean time added laterally. Often the first-formed threads serve as stems to support numerous branches, which in their turn give rise to others. The process may be compared either to vegetation or to crystallisation; but it is clearly analogous to the delicate arrangements which ensue in the particles of coloured powders, such as chalk, vermilion, &c. when these are projected on a cake of wax, after it has been touched with the knob of a charged Leyden phial. We may consider the particles of water as similarly placed upon or beneath a plate of charged air.

Their duration is uncertain, varying from a few minutes after the first appearance to an extent of many hours. It is long when they appear alone, and at great heights, and shorter when they are formed lower, and in the vicinity of other clouds.

This modification, although in appearance almost motionless, is intimately connected with the variable motions of the atmosphere. Considering that clouds of this kind have long been deemed a prognostic of wind, it is extraordinary that the nature of this connection should not have been more studied, as the knowledge of it might have been productive of useful results.

In fair weather, with light variable breezes, the sky is seldom quite clear of small groups of the oblique cirrus, which frequently come on from the leeward, and the direction of their increase is to windward. Continued wet weather is attended with horizontal sheets of this cloud, which subside quickly, and pass to the cirro-stratus. The cirrus pointing upward is a distant indication of rain, and downward a more immediate one of fair weather. Before storms they appear lower and denser, and usually in the quarter opposite to that from which the storm arises. Steady high winds are also preceded and attended by streaks running quite across the sky in the direction they blow in. These, by an optical deception, appear to meet in the horizon.

The relations of this modification with the state of the barometer, thermometer, hygrometer, and electrometer, have not yet been attended to.

Of the cumulus.

Clouds in this modification are commonly of the most dense structure. They are formed in the lower atmosphere, and move along with the current which is next the earth.

A small irregular spot first appears, and is as it were the nucleus on which they increase. The lower surface continues irregularly plane, while the upper rises into conical or hemispherical heaps.

Their appearance, increase, and disappearance, in fair weather, are often periodical, and keep pace with the temperature of the day. Thus they begin to form some hours after sunrise, arrive at their maximum in the hottest part of the afternoon, then go on diminishing, and totally disperse about sunset.

But in changeable weather they partake of the vicissitudes of the atmosphere; sometimes evaporating almost as soon as formed, at others suddenly forming, and as quickly passing to the compound modifications.

The cumulus of fair weather has a moderate elevation and extent, and a well-defined rounded surface. Previous to rain it increases more rapidly, appears lower in the atmosphere, and with its surface full of loose fleeces or protuberances.

The formation of large cumuli to leeward in a strong wind, indicates the approach of a calm with rain. When they do not disappear or subside about sunset, but continue to rise, thunder is to be expected in the night.

Independantly of the beauty and magnificence it adds to the face of nature, the cumulus serves to screen the earth from the direct rays of the sun; by its multiplied reflections to diffuse, and, as it were, economise the light; and also to convey the product of evaporation to a distance from the place of its origin. The relations of the cumulus, with the state of the barometer, &c. have not yet been enough attended to.

It appears that there is a continual evaporation from the base of this cloud, in consequence of its tendency to subside into lower and warmer air. This evaporation is more than compensated during its increase by the deposition from above: while the two effects balance each other, the cloud remains stationary as to bulk; when the supply from above fails, it sinks into the lower air, and totally disappears. This happens usually a little before sunset, because the inequality in the temperatures of the higher and lower air, by virtue of which it subsisted, gives place at that time to the tendency to equal diffusion of the caloric.

Of the stratus.

This modification has a mean degree of density. It is the lowest of clouds, since its inferior surface commonly rests on the earth or water.

Contrary to the last, which may be considered as belonging to the day, this is properly the cloud of night; the time of its first appearance being about sunset. It comprehends all those creeping mists which in calm evenings ascend in spreading sheets, like an inundation of water, from the bottom of valleys, and the surface of lakes, rivers, &c. Its duration is frequently through the night.

On the return of the sun, the level surface of this cloud begins to put on the appearance of cumulus, the whole at the same time separating from the ground. The continuity is next destroyed, and the cloud ascends and evaporates, or passes off with the appearance of the nascent cumulus.

This has been long experienced as a prognostic of fair weather;

> At nebulæ magis ima petunt, campoque recumbunt:—Virgil. Georg. lib. i.

and, indeed, there is none more serene than that which is ushered in by it. The relation of the stratus to the state of the atmosphere as indicated by the barometer, &c. appears, notwithstanding, to have passed hitherto without due attention.

Of the cirro-cumulus.

The cirrus having continued for some time increasing, or stationary, usually passes either to the cirro-cumulus, or the cirro-stratus; at the same time descending to a lower station in the atmosphere.

The cirro-cumulus is formed from a cirrus, or from a number of small separate cirri, by the fibres collapsing, as it were, and passing into small roundish masses, in which the texture of the cirrus is no longer discernible, although they still retain somewhat of the same relative arrangement. This change takes place, either throughout the whole mass at once, or progressively from one extremity to the other. In either case, the same effect is produced on a number of adjacent cirri at the same time, and in the same order. It appears in some instances to be accelerated by the approach of other clouds; and is probably due to the equilibrium of the electric fluid between the cloud and the surrounding atmosphere.

This modification forms a very beautiful sky, sometimes exhibiting numerous distinct beds of these small connected clouds floating at different altitudes.

The cirro-cumulus is frequent in summer, and is attendant on warm and dry weather. It is also occasionally, and more sparingly, seen in the intervals of showers, and in winter. This cloud is a sure prognostic of increased temperature. It may either evaporate, or pass to the cirrus or cirro-stratus.

Of the cirro-stratus.

This cloud appears to result from the subsidence of the fibres of the cirrus to a horizontal position, at the same time that they approach towards each other laterally. The form and relative position, when seen in the distance, frequently give the idea of shoals of fish. Yet in this, as in other instances, the structure must be attended to, rather than the form, which varies much; presenting at other times the appearance of parallel bars, interwoven streaks like the grain of polished wood, &c. It is always thickest in the middle, or at one extremity, and extenuated towards the edge. The distinct appearance of a cirrus does not always precede the production of this and the last modifications.

The cirro-stratus precedes wind and rain, the near or distant approach of which may sometimes be estimated from its greater or less abundance and permanence. It is almost always to be seen in the intervals of storms. Sometimes this and the cirro-cumulus appear together in the sky, and even alternate with each other in the same cloud, when the different evolutions which ensue are a curious spectacle; and a judgment may be formed of the weather likely to ensue, by observing which modification prevails at last. The cirro-stratus is the modification which most frequently and completely exhibits the phenomena of the solar and lunar halo, and (as supposed from a few observations) the parhelion and paraselene also. Hence the reason of the prognostic for foul weather commonly drawn from the appearance of halo. This cloud is among those natural indications which may be trusted in confirmation of the indications of the barometer and hydrometer for rain. It may be reasonably thought to originate from a supervening cold and moist current, occasioning precipitation in the atmosphere below, before it is itself to be perceived. Its appearance often indicates the simple act of subsidence, as in common cases of precipitation in fluids at rest.

Of the cumulo-stratus.

The different modifications which have been just treated of, sometimes give place to each other: at other times two or more appear in the same sky; but in this case the clouds in the same modification lie mostly in the same plane of elevation, those which are more elevated appearing through the intervals of the lower, or the latter shewing dark against the lighter ones above them. When the cumulus increases rapidly, a cirro-stratus is frequently seen to form around its summit, reposing thereon as on a mountain; while the former cloud continues discernible in some degree through it. This state continues but a short time. The cirro-stratus speedily becomes denser, and spreads; while the superior part of the cumulus extends itself, and passes into it, the base continuing as before, and the convex protuberances changing their position till they present themselves laterally and downward. More rarely the cumulus alone performs this evolution, by the movement or mode of increase of its superior part.

In either case, a large lofty dense cloud is formed, which may be compared to a mushroom with a very thick short stem. But when a whole sky is crowded with this modification, the appearances are more indistinct. The cumulus rises through the interstices of the superior clouds; and the whole, seen as it passes off in the distant horizon, presents to the fancy mountains covered with snow, intersected with dark ridges and lakes of water, rocks and towers, &c. The distinct cumulo-stratus is formed in the interval between the first appearance of the fleecy cumulus and the commencement of rain; also during the approach of thunder-storms. The indistinct appearance of it is chiefly in the longer or shorter interval of showers of rain, snow, or hail.

The cumulo-stratus chiefly affects a mean state of the atmosphere, as to pressure and temperature, but is not peculiar to any season; and it may be seen before a fall of snow, as well as before a thunder-storm.

Of the nimbus, or cumulo-cirro-stratus.

Clouds in any one of the preceding modifications, at the same degree of elevation, or two or more of them, at different elevations, may increase so as completely to obscure the sky, and at times put on an appearance of density, which to the inexperienced observer indicates the speedy commencement of rain. It is nevertheless extremely probable, as well from attentive observation, as from a consideration of the several modes of their production, that the clouds, while in any one of these states, do not at any time let fall rain.

Before this effect takes place, they have been uniformly found to undergo a change, attended with appearances sufficiently remarkable to constitute a distinct modification. These appearances, when the rain happens over our heads, are but imperfectly seen. We can then only observe, before the arrival of the denser and lower clouds, or through their interstices, that there exists at a greater altitude a thin light veil, or at least a hazy turbidness. When this has considerably increased, we see the lower clouds spread themselves till they unite in all points, and form one uniform sheet. The rain then commences; and the lower clouds, arriving from the windward, move under this sheet, and are successively lost in it. When the latter cease to arrive, or when the sheet breaks, every one's experience teaches him to expect an abatement or cessation of rain. But there often follows, what seems hitherto to have been unnoticed, an immediate and great addition to the quantity of cloud. For on the cessation of rain, the lower broken clouds which remain rise into cumuli, and the superior sheet puts on the various forms of the cirro-stratus, sometimes passing to the cirro-cumulus.

If the interval is long before the next shower, the cumulo stratus usually makes its appearance, which it also does sometimes very suddenly after the first cessation.

But we see the nature of this process more perfectly, in viewing a distant shower in profile.

If the cumulus be the only cloud present at such a time, we may observe its superior part to become tufted with cirri. Several adjacent clouds also approach, and unite laterally by subsidence.

The cirri increase, extending themselves upward and laterally; after which the shower is seen to commence. At other times the converse takes place of what has been described relative to the cessation of rain. The cirro-stratus is previously formed above the cumulus; and their sudden union is attended with the production of cirri and rain.

In either case the cirri vegetate, as it were, in proportion to the quantity of rain falling; and give the cloud a character by which it is easily known at great distances, and to which, in the language of meteorology, we may appropriate the *nimbus* of the Latins:

> Qualis ubi ad terras abrupto sidere nimbus
> It mare per medium; miseris, heu! prescia longè
> Horrescunt corda agricolis.—Virgil.

When one of these arrives hastily with the wind, it brings but little rain, and frequently some hail or driven snow. In heavy showers the central sheet, once formed, increases to windward, the cirri being propagated above and against the lower current, while the cumuli, arriving with the latter, are successively arrested in their course, and contribute to reinforce the shower.

In continued gentle rains it does not appear necessary, for the resolution of the clouds, that the different modifications should come into actual contact. It is sufficient, that there exist two strata of clouds, one passing beneath the other, and each continually tending to horizontal uniform diffusion. It will rain during this state of the two strata, although they should be separated by an interval of many hundred feet in elevation.

As the masses of cloud are always blended, and their arrangement destroyed, before rain comes on, so the reappearance of those is the signal for its cessation. The thin sheets of cloud which pass over during a wet day, certainly receive from the humid atmosphere a supply proportionate to their consumption; while the latter prevents their increase in bulk Hence a seeming paradox, which yet accords strictly with observation; that for any given hour of a wet day, or any given day of a wet season, the more cloud the less rain. Hence also arise some further reflections on the purpose answered by clouds in the economy of nature. Since rain may be produced by, and continue to fall from, the slightest obscuration of the sky, by the nimbus, that is, by two sheets in different states, while the cumulus, or cumulo-stratus, with the most dark and threatening aspect, passes over without letting fall a drop, until their change of state commences; it should seem that the latter are the reservoirs, in which the water is collected from a large space of atmosphere, for occasional and local irrigation in dry seasons, and by means of which it is also arrested at times in its descent, in the midst of wet ones. In this so evident provision for the sustenance of all animal and vegetable life, as well as for the success of mankind in that pursuit so essential to their welfare, in temperate climates, of cultivating the earth, we may discover the wisdom and goodness of the Creator and Preserver of all things.

The nimbus, although in itself one of the least beautiful clouds, is yet now and then superbly decorated with its attendant, the rainbow, which can only be seen in perfection when backed by the widely extended uniform gloom of this modification.

METHOD, in logic, &c. the arrangement of our ideas in such a regular order, that their mutual connection and dependance may be readily comprehended.

METONYMY, in rhetoric, is a trope in which one name is put for another, on account of the near relation there is between them. By this trope any of the most significant circumstances of a thing are put for the thing itself. See RHETORIC.

METOPE. See ARCHITECTURE.

METRE, in poetry. See HEXAMETER, PENTAMETER, &c.

METROSIDEROS, a genus of the class and order icosandria monogynia. The calyx is five-cleft, half-superior; petals five; stamina very long, standing out; stigma simple; capsule three-celled. There are 13 species, of New Holland, &c.

MEZEREON. See DAPHNE.

MEZZOTINTO. See ENGRAVING.

MIASMA, among physicians, denotes the contagious effluvia of pestilential diseases, whereby they are communicated to people at a distance.

MICA. This stone forms an essential part of many mountains, and has been long known under the names of glacies Mariæ, and Muscovy glass. It consists of a great number of thin laminæ adhering to each other, sometimes of a very large size. Specimens have been found in Siberia nearly $2\frac{1}{2}$ yards square.

It is sometimes crystallized; its primitive form is a rectangular prism, whose bases are rhombs with angles of 120° and 60°: its integrant molecule has the same form. Sometimes it occurs in rectangular prisms, whose bases also are rectangles, and sometimes also in short six-sided prisms; but it is much more frequent in plates or scales of no determinate figure or size.

Its texture is foliated. Its fragments flat. The lamellæ flexible, and somewhat elastic. Very tough. Often absorbs water. Specific gravity from 2.6546 to 2.9342. Feels smooth, but not greasy. Powder feels greasy. Colour, when purest, silver white or grey; but it occurs also yellow, greenish, reddish brown, and black. Mica is fusible by the blowpipe into a white, grey, green, or black enamel; and this last is attracted by the magnet. Spanish wax rubbed by it becomes negatively electric.

A specimen of mica, analysed by Vauquelin, contained

50.00	silica
35.00	alumina
7.00	oxide of iron
1.35	magnesia
1.33	lime.
94.68	

Mica has long been employed as a substitute for glass. A great quantity of it is said to be used in the Russian marine for panes to the cabin-windows of ships; it is preferred, because it is not so liable as glass to be broken by the agitation of the ship. It is also used in our navy for lantherns, for the use of the powder-rooms.

MICHELIA, a genus of the octandria polygynia class of plants, the flower of which consists of eight petals; the fruit consists of a number of globose unilocular berries, disposed in a cluster; in each of which there are four seeds, convex on one side, and angular on the other. There are two species, trees of the East Indies.

MICHAUXIA, a genus of the class and order octandria monogynia. The calyx is 16-parted; corolla wheel-shaped, 8-parted; nect. 8-valved, staminiferous; caps. 8-celled, many-seeded. There is one species, a biennial of Aleppo, resembling the campanula.

MICROMETER, an astronomical machine, which, by means of a screw, serves to measure extremely small distances in the heavens, &c. and that to a great degree of accuracy.

The micrometer consists of a graduated circle (Plate Miscel. fig. 162), of a screw $q\,o$, and its index $q\,r$. The threads of the screw are such, that 50 make the length of one inch exactly. When it is to be used, the point o is set to the side of the part to be measured, and then the index is turned about with the finger, till the eye perceives the point has just passed over the diameter of that part; then the number of turns, and parts of a turn, shewn by the graduated circle, will give the dimensions in parts of an inch, as we shall shew by the following example: Suppose it is required to measure the diameter of a human hair, and I observe the index is turned just once round while the point o passes over it; then it is plain the diameter of the hair in the image is $\frac{1}{50}$th of an inch. Now if the microscope, I D E F, $d\,e\,f$, magnifies 6 times, or makes the image 6 times larger in diameter than the object, then is the diameter of the hair itself but $\frac{1}{6}$th of $\frac{1}{50}$, that is, but $\frac{1}{300}$th, part of an inch.

Also it is to be observed, that as there are ten large divisions, and twenty small ones, on the micrometer plate, so each of those small divisions is the $\frac{1}{20}$th of $\frac{1}{50}$th, or the $\frac{1}{1000}$th part of an inch. Therefore, if, in measuring any part of an object, you observe how many of these smaller divisions are passed over by the index, you will have so many thousandth parts of an inch for the measure required.

ilium. CC, the acetabula. DD, the ossa ischium. E, the coccyx. F, the lower part of the rectum. GG, the vagina. H, the os internum stretched open about a finger breadth, with the membranes and waters in time of labour-pains. II, the inferior part of the uterus, stretched with the waters which are below the head of the child that presents. KK, the two placentas adhering to the posterior part of the uterus, the two fœtuses lying before them, one with its head in a proper position at the inferior part of the uterus, and the other situated preternaturally with the head to the fundus; the bodies of both are here entangled in their proper funis, which frequently happens in the natural as well as preternatural positions. LLL, the membranes belonging to each placenta.

Fig. 6. exhibits, in a lateral view and longitudinal division of the parts, the gravid uterus when labour is somewhat advanced. A, the lowest vertebra of the back; the distance from which to the last-mentioned vertebra is here shewn by dotted lines. CC, the usual thickness and figure of the uterus when extended by the waters at the latter part of pregnancy. D, the same contracted and grown thicker after the waters are evacuated. EE, the figure of the uterus when pendulous. FF, the figure of the uterus when stretched higher than usual, which generally occasions vomitings and difficulty of breathing. G, the os pubis of the left side. HH, the os internum. I, the vagina. K, the left nympha. L, the labium pudendi of the same side. M, the remaining portion of the bladder. N, the anus. OP, the left hip and thigh.

Fig. 7. exhibits the forehead of the fœtus turned backwards to the os sacrum, and the occiput below the pubes; by which means the narrow part of the head is to the narrow part of the pelvis, that is, between the inferior parts of the ossa ischium. A, the uterus contracted closely to the fœtus after the waters are evacuated. BCD, the vertebræ of the loins, os sacrum, and coccyx. E, the anus. F, the left hip. G, the perinæum. H, the os externum beginning to dilate. I, the os pubis of the left side. K, the remaining portion of the bladder. L, the posterior part of the os uteri.

Fig. 8. presents a lateral internal view of a distorted pelvis, divided longitudinally, with the head of a fœtus of the seventh month passing the same. ABC, the os sacrum and coccyx. D, the os pubis of the left side. E, the tuberosity of the os ischium of the same side.

Fig. 9. presents a side view of a distorted pelvis, divided longitudinally, with the head of a full-grown fœtus squeezed into the brim, the parietal bones decussating each other, and compressed into a conical form. ABC, the os sacrum and coccyx. D, the os pubis of the left side. E, the tuberosity of the os ischium. F, the processus acutus. G, the foramen magnum.

Fig. 10. shews in what manner the head of the fœtus is helped along with the forceps, when it is necessary for the safety of either mother or child. A,A,B,C, the vertebræ of the loins, the os sacrum, and coccyx. D, the os pubis of the left side. E, part of the bladder. FF, the intestinum rectum. GGG, the uterus. H, the mons Veneris. I, the clitoris with the left nympha. X, the corpus cavernosum clitoridis. V, the meatus urinarius. K, the left labium pudendi. L, the anus. N, the perinæum. QP, the left hip and thigh. R, the skin and muscular part of the loins.

Fig. 11. shews in a lateral view the face of the child, forced down into the lower part of the pelvis, the chin below the pubes, and the vertex in the cavity of the os sacrum; the waters being all discharged, the uterus appears closely attached to the body of the child.

Fig. 12. shews the head of the child in the same position as the eleventh figure. AB, the vertebræ of the loins, os sacrum, and coccyx. C, the os pubis of the left side. D, the lower part of the rectum. E, the perinæum. F, the left labium pudendi. GGG, the uterus.

Fig. 13. shews the head of the fœtus, by strong labour-pains, squeezed into a longish form, with a tumour on the vertex, from long compression of the head in the pelvis. K, the tumour on the vertex. L, the forceps. M, the urinary bladder much distended with a large quantity of urine, from the long pressure of the head against the urethra. N, the under part of the uterus. OO, the os uteri.

Fig. 14. exhibits a front view of the pelvis, the breech of the fœtus presenting, and dilating the os internum, the membranes having been prematurely ruptured.

Fig. 15. represents in a front view of the pelvis, the fœtus compressed by the contraction of the uterus into a round form, the fore parts of the former being towards the inferior part of the latter, and one foot and hand fallen down into the vagina. In this figure, the anterior part of the pelvis is removed by a longitudinal section, through the middle of the foramen magnum. AA, the superior portion of the ossa ilium. BB, the uterus. C, the mouth of the uterus shooting and appearing in OOOO the vagina. D, the inferior and posterior part of the os externum. EEEE, the remaining parts of the ossa pubis and ischium. FFF, the adipose membrane.

Fig. 16. represents the forceps and blunt hook. *a*, the straight forceps. *b*, the posterior part of a single blade. *c*, the blunt hook; which is employed to assist the extraction of the head after the cranium is opened, by introducing the small end along the ear on the outside of the head, to above the under jaw, where the point is to be fixed; the other extremity of the hook being held with one hand, while two fingers of the other are to be introduced into the opening. The small end is useful in abortions, to draw down the secundines when they are not expelled by labour-pains, or cannot be extracted by the fingers. The large hook at the opposite end is useful to assist the extraction of the body when the breech presents, but should be used with much caution.

Fig. 17. A represents the whole bone fillet, which, when the operator is not provided with forceps, may sometimes be useful in laborious cases. BB, two views of a pessary for the prolapsus uteri. C, a round pessary which is in more general use than the former. DD, two views of a female catheter.

Fig. 18. *a*, represents a pair of curved crotchets, locked in the same manner as the forceps: the dotted lines indicate a sheath, contrived to defend the point till it is introduced sufficiently high. *b*, gives a view of the back part of one of the crotchets. *c*, a front view of the point. *d*, the scissars for perforating the cranium, in very narrow and distorted pelvises.

MIGRATION, *of birds.* It has been generally believed, that many different kinds of birds annually pass from one country to another, and spend the summer or the winter where it is most agreeable to them; and that even the birds of our own island will seek the most distant southern regions of Africa, when directed by a peculiar instinct to leave their own country. It has long been an opinion pretty generally received, that swallows reside during the winter season in the warm southern regions; and Mr. Adanson particularly relates his having seen them at Senegal, when they were obliged to leave this country. But besides the swallow, Mr. Pennant enumerates many other birds which migrate from Britain at different times of the year, and are then to be found in other countries; after which they again leave these countries, and return to Britain.

1. Crows. Of this genus, the hooded crow migrates regularly with the woodcock. It inhabits North Britain the whole year: a few are said annually to breed on Dartmoor, in Devonshire. It breeds also in Sweden and Austria; in some of the Swedish provinces it only shifts its quarters, in others it resides throughout the year. Our author is at a loss for the summer retreat of those birds which visit us in such numbers in winter, and quit our country in the spring; and for the reason why a bird whose food is such that it may be found at all seasons in this country, should leave us.

2. Cuckoo, disappears early in autumn; the retreat of this and the following bird is quite unknown to us.

3. Wryneck, is a bird that leaves us in the winter. If its diet is ants alone, as several assert, the cause of its migration is very evident. This bird disappears before winter, and revisits us in the spring, a little earlier than the cuckoo.

4. Hoopoe. Comes to England but by accident. Mr. Pennant once indeed heard of a pair that attempted to make their nest in a meadow at Selborne, Hampshire, but were frightened away by the curiosity of people. It breeds in Germany.

5. Grouse. The whole tribe, except the quail, live here all the year round; that bird either leaves us, or else retires towards the sea-coasts.

6. Pigeons. Some few of the ring-doves breed here; but the multitude that appear in winter are so disproportioned to what continue here the whole year, as to make it certain that the greatest part quit the country in the spring. It is most probable they go to Sweden to breed, and return thence in autumn: as Mr. Ekmark informs us, they entirely quit that country before winter. Multitudes of the common wild pigeons also make the northern retreat, and visit us in winter; though numbers breed in the high cliffs in all parts of this island. The turtle also probably leaves us in the winter, at least changes its place, removing to the southern counties.

7. Stare, breeds here. Possibly several remove to other countries for that purpose, since the produce of those that continue

here seems unequal to the clouds of them that appear in winter. It is not unlikely that many migrate into Sweden, whither Mr. Berger observes they return in spring.

8. Thrushes. The fieldfare and the redwing breed pass their summers in Norway and other cold countries; their food is berries, which abounding in our kingdoms tempt them hither in the winter. These two, and the Royston crow, are the only land birds that regularly and constantly migrate into England, and do not breed here. The hawfinch and crossbill come hither at such uncertain times as not to deserve the name of birds of passage.

9. Chatterer. The chatterer appears annually about Edinburgh in flocks during winter, and feeds on the berries of the mountain-ash. In South Britain it is an accidental visitant.

10. Grosbeaks. The grosbeak and crossbill come hither but seldom; they breed in Austria. The pine grosbeak probably breeds in the forests of the Highlands of Scotland.

11. Buntings. All the genus inhabit England throughout the year, except the greater brambling, which is forced hither from the north in very severe seasons.

12. Finches. All continue in some part of these kingdoms, except the siskin, which is an irregular visitant, said to come from Russia. The linnets shift their quarters, breeding in one part of this island, and remove with their young to others. All finches feed on the seeds of plants.

13. Larks, fly-catchers, wagtails, and warblers. All these birds feed on insects and worms; yet only part of them quit these kingdoms, though the reason of migration is the same to all. The nightingale, black-cap, fly-catcher, willow-wren, wheatear, and white-throat, leave us before winter, while the small and delicate golden-crested wren braves our severest frosts. The migrants of this genus continue longest in Great Britain in the southern counties, the winter in those parts being later than in those of the north; Mr. Stillingfleet having observed several wheatears in the isle of Purbeck on the 18th of November. As these birds are incapable of very distant flights, Spain, or the south of France, is probably their winter asylum.

14. Swallow and goat-sucker. Every species disappears at the approach of winter.

Water-Fowl, cloven-footed.

15. Herons. The white heron is an uncommon bird, and visits us at uncertain seasons; the common kind and the bittern never leave us.

16. Curlews. The curlew breeds sometimes on our mountains; but, considering the vast flights that appear in winter, it is probable that the greater part retire to other countries; the whimbrel breeds on the Grampian hills, in the neighbourhood of Invercauld.

17. Snipes. The woodcock breeds in the moist woods of Sweden, and other cold countries. Some snipes breed here; but the greatest part retire elsewhere, as do every other species of this genus.

18. Sandpipers. The lapwing continues here the whole year; the ruff breeds here, but retires in winter; the redshank and sandpiper breed in this country, and reside here. All the others absent themselves during summer.

19. Plovers and oyster-catchers. The long-legged plover and the sanderling visit us only in winter: the dottrel appears in spring and in autumn; yet, what is very singular, we do not find it breeds in South Britain. The oyster-catcher lives with us the whole year. The Norfolk plover and the sea-lark breed in England. The green plover breeds on the mountains of the north of England, and on the Grampian hills.

We must here remark, that every species of the genera of curlews, woodcocks, sandpipers, and plovers, that forsake us in the spring, retire to Sweden, Poland, Prussia, Norway, and Lapland, to breed; as soon as the young can fly, they return to us again, because the frosts which set in early in those countries totally deprive them of the means of subsisting; as the dryness and hardness of the ground, in general, during our summer, prevent them from penetrating the earth with their bills, in search of worms, which are the natural food of these birds.

20. Rails and gallinules. Every species of these two genera continue with us the whole year; the land-rail excepted, which is not seen here in winter. It likewise continues in Ireland only during the summer-months, when it is very numerous.

Finned-footed Water-birds.

21. Phalaropes visit us but seldom; their breeding-place is Lapland and other arctic regions.

22. Grebes. The great-crested grebe, the black and white grebe, and little grebe, breed with us, and never migrate; the others visit us accidentally, and breed in Lapland.

Web-footed Birds.

23. Avoset. Breed near Fossdike in Lincolnshire, but quit their quarters in winter. They are then shot in different parts of the kingdom; which they visit not regularly, but accidentally.

24. Auks and guillemots. The great auk or pinguin sometimes breeds in St. Kilda. The auk, the guillemot, and puffin, inhabit most of the maritime cliffs of Great Britain, in amazing numbers, during summer. The black guillemot breeds in the Bass Isle, and in St. Kilda, and sometimes in Llandinno rocks. We are at a loss for the breeding-place of the other species; neither can we be very certain of the winter residence of any of them, except of the lesser guillemot and black-billed auk, which, during winter, visit in vast flocks the frith of Forth.

25. Divers, chiefly breed in the lakes of Sweden and Lapland, and in some countries near the pole; but some of the red-throated divers, the northern, and the imber, may breed in the north of Scotland and its isles.

26. Terns. Every species breeds here, but leaves us in the winter.

27. Petrels. The fulmar breeds in the isle of St. Kilda, and continues there the whole year except September and part of October. The shearwater visits the Isle of Man in April; breeds there; and, leaving it in August or the beginning of September, disperses over all parts of the Atlantic ocean. The stormfinch is seen at all distances from land on the same vast watery tract; nor is ever found near the shore except by some very rare accident, unless in the breeding-season. Mr. Pennant found it on some little rocky isles, off the north of Skye. It also breeds in St. Kilda. He suspects too that it nestles on the Blasquet isles off Kerry, and that it is the gourder of Mr. Smith.

28. Mergansers. This whole genus is mentioned among the birds that fill the Lapland lakes during summer. Mr. Pennant has seen the young of the red-breasted in the north of Scotland; a few of these, and perhaps of the goosanders, may breed there.

29. Ducks. Of the numerous species that form this genus, we know of few that breed here; the swan and goose, the shield-duck, the eider-duck, a few shovellers, garganies, and teals, and a very small portion of the wild ducks.

The rest contribute to form that amazing multitude of water-fowl that annually repair from most parts of Europe to the woods and lakes of Lapland and other arctic regions, there to perform the functions of incubation and nutrition in full security. They and their young quit their retreat in September, and disperse themselves over Europe. With us they make their appearance the beginning of October; circulate first round our shores; and, when compelled by severe frost, betake themselves to our lakes and rivers. Of the web-footed fowl there are some of hardier constitutions than others; these endure the ordinary winters of the more northern countries; but when the cold reigns there with more than common rigour, they repair for shelter to these kingdoms: this regulates the appearance of some of the diver kind, as also of the wild swans, the swallow-tailed shield-duck, and the different sorts of goosanders which then visit our coasts. Barentz found the barnacles with their nests in great numbers in Nova Zembla.

30. Corvorants. The corvorant and shag breed on most of our high rocks: the gannet in some of the Scotch isles, and on the coast of Kerry; the two first continue on our shores the whole year. The gannet disperses itself all round the seas of Great Britain, in pursuit of the herring and pilchard, and even as far as the Tagus to prey on the sardina.

MILE, a measure of length or distance, containing eight furlongs.

The English statute-mile is fourscore chains, or 1760 yards; that is, 5280 feet. See Chain, Yard, and Foot.

We shall here give a table of the miles in use among the principal nations of Europe, in geometrical paces, 60,000 of which make a degree of the equator.

	Geometrical paces.
Mile of Russia	750
of Italy	1000
of England	1250
of Scotland and Ireland	1500
of Poland	3000
of Spain	3428
of Germany	4000
of Sweden	5000
of Denmark	5000
of Hungary	6000

MILIARY FEVER, a malignant fever, so called from the eruption of certain pustules resembling millet-seeds. See Medicine.

MILIUM, millet, a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the 4th order, gramina. The calyx is bivalved and uniflorous; the corolla is very short; the stigmata pencil-like. There are 12 species, of which the most remarkable is the effusum, or common millet.

MILK, is a fluid secreted by the female of all those animals denominated mammalia, and intended evidently for the nourishment of her offspring.

The milk of every animal has certain peculiarities which distinguish it from every other milk. But the animal whose milk is most made use of by man as an article of food, and with which, consequently, we are best acquainted, is the cow. Chemists, therefore, have made choice of cow's milk for their experiments.

Milk is an opaque fluid, of a white colour, a slight peculiar smell, and a pleasant sweetish taste. When newly drawn from the cow, it has a taste very different from that which it acquires after it has been kept for some hours.

It is liquid, and wets all those substances which can be moistened in water; but its consistence is greater than that of water, and it is slightly unctuous. Like water, it freezes when cooled down to about 30°; but Parmentier and Deyeux, to whom we are indebted for by far the completest account of milk hitherto published, found that its freezing-point varies considerably in the milk of different cows, and even of the same cow at different times. Milk boils also when sufficiently heated; but the same variation takes place in the boiling-point of different milks, though it never deviates very far from the boiling-point of water. Milk is specifically heavier than water, and lighter than blood; but the precise degree cannot be ascertained, because almost every particular milk has a specific gravity peculiar to itself.

When milk is allowed to remain for some time at rest, there collects on its surface a thick unctuous yellowish-coloured substance, known by the name of cream. The cream appears sooner on milk in summer than in winter, evidently owing to the difference of temperature. In summer, about four days of repose are necessary before the whole of the cream collects on the surface of the liquid; but in winter it requires at least double the time.

After the cream is separated, the milk which remains is much thinner than before, and it has a blueish-white colour. If it is heated to the temperature of 100°, and a little rennet (which is water digested with the inner coat of a calf's stomach, and preserved with salt) is poured into it, coagulation ensues; and if the coagulum is broken, the milk very soon separates into two substances; a solid white part known by the name of curd, and a fluid part called whey.

Thus we see that milk may be easily separated into three parts; namely, cream, curd, and whey.

1. Cream is of a yellow colour, and its consistence increases gradually by exposure to the atmosphere. In three or four days it becomes so thick that the vessel which contains it may be inverted without risking any loss. In eight or ten days more, its surface is covered over with mucors and byssi, and it has no longer the flavour of cream, but of very fat cheese. This is the process for making what in this country is called a cream-cheese.

Cream possesses many of the properties of an oil. It is specifically lighter than water; it has an unctuous feel; stains clothes precisely in the manner of oil; and if it is kept fluid, it contracts at last a taste which is very analogous to the rancidity of oils. When kept boiling for some time, a little oil makes its appearance, and floats upon its surface. Cream is neither soluble in alcohol nor in oils. These properties are sufficient to shew us, that it contains a quantity of oil; but this oil is combined with a part of the curd, and mixed with some serum; cream, then, is composed of a peculiar oil, curd, and serum. The oil may be easily obtained separate by agitating the cream for a considerable time. This process, known to every body, is called churning. After a certain time, the cream separates into two portions; one fluid, and resembling creamed milk; the other solid, and called butter.

Butter is of a yellow colour, possesses the properties of an oil, and mixes readily with other oily bodies. When heated to the temperature of 96°, it melts, and becomes transparent; if it is kept for some time melted, some curd and water, or whey, separates from it, and it assumes exactly the appearance of oil. But this process deprives it in a great measure of its peculiar flavour.

When butter is kept for a certain time, it becomes rancid, owing in a good measure to the presence of these foreign ingredients; for if butter is well-washed, and a great portion of these matters separated, it does not become rancid nearly so soon as when it is not treated in this manner. It was formerly supposed that this rancidity was owing to the developement of a peculiar acid; but Parmentier and Deyeux have shewn that no acid is present in rancid butter. When butter is distilled, there comes over water an acid, and an oil, at first fluid, but afterwards concrete. The carbonaceous residuum is but small.

Butter may be obtained by agitating cream newly taken from milk, or even by agitating milk newly drawn from the cow; but it is usual to allow cream to remain for some time before it is churned. Now cream, by standing, acquires a sour taste; butter, therefore, is commonly made from sour cream. Fresh cream requires at least four times as much churning before it yields its butter, as sour cream does; consequently cream acquires, by being kept for some time, new properties, in consequence of which it is more easily converted into butter. When very sour cream is churned, every one who has paid the smallest attention must have perceived, that the buttermilk, after the churning, is not nearly so sour as the cream had been. The butter, in all cases, is perfectly sweet; consequently the acid which had been evolved has in a great measure disappeared during the process of churning. It has been ascertained, that cream may be churned, and butter obtained, though the contact of atmospheric air should be excluded. On the other hand, it has been affirmed, that when cream is churned in contact with air, it absorbs a considerable quantity of it.

In all cases there is a considerable extrication of gas during the churning of butter. From the phenomena, it can scarcely be doubted that this gas is carbonic acid. Dr. Young affirms, that during the churning there is an increase of temperature amounting to four degrees.

These facts shew that considerable chemical changes go on during the process of churning. The agitation keeps the different substances in contact, and enables them to act upon each other. The expulsion of carbonic acid accounts for the diminution of acidity after churning; while the other phenomena would lead us to suppose that the cream, before it becomes butter, unites to a new portion of oxygen.

The affinity of the oil of cream for the other ingredients is such, that it never separates completely from them. Not only are curd and whey always found in the cream, but some of this oil is constantly found in creamed milk and whey; for it has been ascertained by actual experiment, that butter may be obtained by churning whey. 27 Scotch pints of whey yield at an average about a pound of butter. This accounts for a fact well known to those who superintend dairies, that a good deal more butter may be obtained from the same quantity of milk, provided it is churned as drawn from the cow, than when the cream alone is collected and churned.

The buttermilk, as Parmentier and Deyeux ascertained by experiment, possesses precisely the properties of milk deprived of cream.

2. Curd, which may be separated from creamed milk by rennet, has many of the properties of coagulated albumen. It is white and solid; and when all the moisture is squeezed out, it has a good deal of brittleness. It is insoluble in water; but pure alkalies and lime dissolve it readily, especially when assisted by heat; and when fixed alkali is used, a great quantity of ammonia is emitted during the solution. The solution of curd in soda is of a red colour, at least if heat is employed; owing probably to the separation of charcoal from the curd by the action of the alkali. Indeed, when a strong heat has been used, charcoal precipitates as the solution cools. The matter dissolved by the alkali may be separated from it by means of an acid; but it has lost all the properties of curd. It is of a black colour, melts like tallow by the application of heat, leaves oily stains on paper, and never acquires the consistence of curd. Hence it appears that curd, by the action of a fixed alkali, is decomposed, and converted into two new substances; ammonia, and oil or rather fat.

Curd is soluble also in acids. If, over curd newly precipitated from milk, and not dried, there are poured eight parts of water, containing as much of any of the mineral acids as gives it a sensibly acid taste, the whole is dissolved after a little boiling. Acetic acid and lactic acid do not dissolve curd, when very much diluted; but these acids, when concentrated, dissolve it readily, and in considerable quantity. It is remarkable enough, that concentrated vegetable acids dissolve curd readily, but have very little action on it when they are very much diluted; whereas the mineral acids dissolve it when much diluted; but when concentrated, have either very little effect on it, as sulphuric acid, or decompose it, as nitric acid. By means of this last acid, as Berthollet discovered, a quantity of azotic gas may be obtained from curd.

Curd, as is well known, is used in making cheese; and the cheese is the better the more it contains of cream, or of that oily matter which constitutes cream. It is well known to cheesemakers, that the goodness of it depends in a great measure on the manner of separating the whey from the curd. If the milk is much heated, the coagulum broken in pieces, and the whey forcibly separated, as is the practice in many parts of Scotland, the cheese is scarcely good for any thing; but the whey is delicious, especially the whey last squeezed out, and butter may be obtained from it in considerable quantity. This is a full proof that nearly the whole creamy part of the milk has been separated with the whey. Whereas if the milk is not too much heated (about 100 degrees is sufficient), if the coagulum is allowed to remain unbroken, and the whey separated by very slow and gentle pressure, the cheese is excellent; but the whey is almost transparent, and nearly colourless.

Good cheese melts at a moderate heat; but bad cheese, when heated, dries, curls, and exhibits all the phenomena of burning horn. Hence it is evident, that good cheese contains a quantity of the peculiar oil which constitutes the distinguishing characteristic of cream; whence its flavour and smell.

This resemblance of curd and albumen makes it probable that the coagulation of milk and albumen depends upon the same cause. Heat, indeed, does not coagulate milk, because the curd in it is diluted with too large a quantity of water; but if milk is boiled in contact with air, a pellicle soon forms on its surface, which has the properties of curd. If this pellicle is removed, another succeeds; and by continuing the boiling, the whole of the curdy matter may be separated from milk. When this pellicle is allowed to remain, it falls at last to the bottom of the vessel; where, being exposed to a greater heat, it becomes brown, and communicates to milk that disagreeable taste which, in this country, is called a *singed* taste. It happens more readily when milk is boiled along with rice, flour, &c.

If to boiling milk there is added as much of any neutral salt as it is capable of dissolving, or of sugar, or of gum arabic, the milk coagulates and the curd separates. Alcohol also coagulates milk; as do all acids, rennet, and the infusion of the flowers of artichoke and of the thistle. If milk is diluted with ten times its weight of water, it cannot be made to coagulate at all.

3. Whey, after being filtred to separate a quantity of curd which still continues to float through it, is a thin pellucid fluid, of a yellowish-green colour and pleasant sweetish taste, in which the flavour of milk may be distinguished. It always contains some curd: nearly the whole may be separated by keeping the whey for some time boiling; a thick white scum gathers on the surface, which is known by the name of skim-curd. When this scum, which consists of the curdy part, is carefully separated, the whey, after being allowed to remain at rest for some hours, to give the remainder of the curd time to precipitate, is decanted off almost as colourless as water, and scarcely any of the peculiar taste of milk can be distinguished in it. If it is now slowly evaporated, it deposits at last a number of white-coloured crystals, which are sugar of milk. Towards the end of the evaporation, some crystals of muriat of potass and of muriat of soda make their appearance. According to Scheele, it contains also a little phosphat of lime, which indeed may be precipitated by ammonia.

After the salts have been obtained from whey, what remains concretes into a jelly on cooling. Hence it follows that whey also contains gelatine. Whey, then, is composed of water, sugar of milk, gelatine, muriat of potass, and phosphat of lime. The other salts which are sometimes found in it, are only accidentally present.

If whey is allowed to remain for some time, it becomes sour, owing to the formation of a peculiar acid known by the name of lactic acid. It is to this property of whey that we are to ascribe the acidity which milk contracts; for neither curd nor cream, perfectly freed from serum, seems susceptible of acquiring acid properties. Hence the reason also that milk, after it becomes sour, always coagulates. Boiled milk has the property of continuing longer sweet, but it is singular enough that it runs sooner to putrefaction, than ordinary milk.

The acid of milk differs considerably from the acetic: yet vinegar may be obtained from milk by a very simple process. If to somewhat more than 8 lbs. troy of milk six spoonfuls of alcohol are added, and the mixture well corked is exposed to a heat sufficient to support fermentation, provided attention is paid to allow the carbonic acid gas to escape from time to time, the whey, in about a month, will be found converted into vinegar.

Milk is almost the only animal substance which may be made to undergo the vinous fermentation, and to afford a liquor resembling wine or beer, from which alcohol may be separated by distillation. This singular fact seems to have been first discovered by the Tartars; they obtain all their spirituous liquors from mare's milk. It has been ascertained, that milk is incapable of being converted into wine till it has become sour; after this nothing is necessary but to place it in the proper temperature; the fermentation begins of its own accord, and continues till the formation of wine is completed. Scheele had shewed that milk was capable of fermenting, and that a great quantity of carbonic acid gas was extricated from it during this fermentation; but he did not suspect that the result of this fermentation was the formation of an intoxicating liquor similar to wine. The Tartars call the vinous liquid which they prepare koumiss. A very exact account of its preparation and medical uses has been published by Dr. Guthrie.

When milk is distilled by the heat of a water-bath, there comes over water having the peculiar odour of milk: which putrefies; and consequently contains, besides mere water, some of the other constituent parts of milk. After some time the milk coagulates, as always happens when hot albumen acquires a certain degree of concentration. There remains behind a thick unctuous yellowish-white substance, to which Hoffman gave the name of franchippan. This substance, when the fire is increased, yields at first a transparent liquid, which becomes gradually more coloured; some very fluid oil comes over, then ammonia, an acid, and at last a very thick black oil. Towards the end of the process carbureted hydrogen gas is disengaged. There remains in the retort a coal which contains carbonat of potass, muriat of potass, and phosphat of lime; and sometimes magnesia, iron, and muriat of soda.

Thus we see that cow's milk is composed of the following ingredients:

1. Water,	6. Muriat of soda,
2. Oil,	7. Muriat of potass,
3. Curd,	8. Sulphur,
4. Gelatine,	9. Phosphat of lime.
5. Sugar of milk.	

The milk of all other animals, as far as it has hitherto been examined, consists nearly of the same ingredients: but there is a very great difference in their proportion.

Woman's milk has a much sweeter taste than cow's milk. When allowed to remain at rest for a sufficient time, a cream gathers on its surface. This cream is more abundant than in cow's milk, and its colour is usually much whiter. After it is separated, the milk is exceedingly thin; and has the appearance rather of whey with a blueish-white colour, than of cream-milk.

None of the methods by which cow's milk is coagulated succeed in producing the coagulation of woman's milk. It is certain, however, that it contains curd; for if it is boiled, pellicles form on its surface, which have all the properties of curd. Its not coagulating, therefore, must be attributed to the great quantity of water with which the curd is diluted.

Though the cream is churned ever so long, no butter can be obtained from it; but if, after being agitated for some hours, it is allowed to remain at rest for a day or two, it separates into two parts: a fluid which occupies the inferior part of the vessel, pellucid and colourless like water; and a thick white unctuous fluid which swims on the surface. The lowermost fluid contains sugar of milk and some curd; the uppermost does not differ from cream except in consistence. The oily part of the cream, then, cannot be separated by agitation from the curd. This cream contains a greater portion of curd than the cream of cow's milk.

When this milk, after the curd is separated from it, is slowly evaporated, it yields crystals of sugar of milk and of muriat of soda. The quantity of sugar is rather greater than in cow's milk. According to Haller, the sugar obtained from cow's milk is to that obtained from an equal quantity of woman's milk as 35 to 58, and sometimes as 37 to 67, and in all the intermediate ratios.

Thus it appears that woman's milk differs from that of cow's in three particulars:

It contains a much smaller quantity of curd. Its oil is so intimately combined with its curd that it does not yield butter. It contains rather more sugar of milk.

Parmentier and Deyeux ascertained, that the quantity of curd in woman's milk increases in proportion to the time after delivery. Nearly the same thing has been observed with respect to cow's milk.

Ass's milk has a very strong resemblance to human milk. It has nearly the same colour, smell, and consistence. When left at rest for a sufficient time, a cream forms upon its surface, but by no means in such abundance as in woman's milk. This cream, by very long agitation, yields a butter, which is always soft, white, and tasteless; and, what is singular, very readily mixes again with the buttermilk; but it may be again separated by agitation, while the vessel which contains it is plunged in cold water. Creamed ass's milk is thin, and has an agreeable sweetish taste. Alcohol and acids separate from it a little curd, which has but a small degree of consistence. The serum yields sugar of milk and muriat of lime.

Ass's milk therefore differs from cow's milk in three particulars:

Its cream is less abundant and more insipid. It contains less curd. It contains more sugar of milk: the proportion is 35 to 80.

Goat's milk, if we except its consistence, which is greater, does not differ much from cow's milk. Like that milk it throws up abundance of cream, from which butter is easily obtained. The creamed milk coagulates just as cow's milk, and yields a greater quantity of curd. Its whey contains sugar of milk, muriat of lime, and muriat of soda.

Ewe's milk resembles almost precisely that of the cow. Its cream is rather more abundant, and yields a butter which never acquires the consistence of butter from cow's milk. Its curd has a fat and viscid appearance, and is not without difficulty made to assume the consistence of the curd of cow's milk. It makes excellent cheese.

Mare's milk is thinner than that of the cow, but scarcely so thin as human milk. Its cream cannot be converted into butter by agitation. The creamed milk coagulates precisely as cow's milk, but the curd is not so abundant. The serum contains sugar of milk, sulphat of lime, and muriat of lime.

MILKY-WAY, in astronomy, a broad track or path, encompassing the whole heavens, distinguishable by its white appearance: whence it obtains its name. See Astronomy.

MILL, a machine or engine for grinding corn, &c. of which there are several kinds, according to the various methods of applying the moving power; as water-mills, wind-mills, mills worked by horses, &c.

In water-mills the momentum of the water is the moving power; and the attrition of the two stones in grinding is the force to be overcome. Of these there are two kinds, viz. those where the force of the water is applied above the wheel, and those where it is applied below the wheel; the former being called overshot, and the latter undershot mills: and to these we may add a breast-mill, where the water strikes against the middle of the wheel.

Few people are ignorant that corn is ground by two mill-stones, placed one above the other, without touching. The lower, or nether, mill-stone, is immoveable; but the upper one turns upon a spindle. The opposite surfaces of the two stones, which act to grind the corn, are not plane or flat; but the upper one is hollow, and the under one swells upwards; each of them being of a conic figure, whose axis indeed is very short in proportion to the diameter of its base: for the upper one, being six feet in diameter, is hollowed but about one inch at its centre; and the lower one rises but about three-fourths of an inch. These two mill-stones come nearer and nearer towards their circumference, whereby the corn that falls from the hopper has room to insinuate between them as far as two-thirds of the radius, which is the place where it begins to be ground, and where it makes the greatest resistance that it is capable of; the space between the stones being in that place but about two-thirds or three-fourths of the thickness of a grain of corn. But as the millers have the means of raising or sinking the upper stone a little, they can proportion its distance from the lower one, according as they would have the flour finer or coarser.

The circular motion of the upper mill-stone brings the corn out of the hopper by jerks, and causes it to recede from the centre towards the circumference; where being quite reduced to flour, it is thrown out of the mill, by the centrifugal force of the stone, through a hole provided on purpose.

As the water acts upon an overshot-mill both by impulse and weight, so does it likewise upon a breast-mill, or that where the water comes upon the breast or middle part of the wheel: and here, though the weight of the water is not so great as in the overshot mill, being contained in the buckets of the lower quarter only; yet the impulse of the water is much greater, the height of the water being increased nearly the semidiameter of the great wheel, all other things being equal. If the height of the water remains the same, the aperture of the penstock, or flood-gate, must be enlarged to nearly twice the area, that the force may be the same; so that to produce the same effect, twice as much water is necessary for a breast-mill as for an overshot one, every thing else being the same.

As to the undershot-mill, it is evident that there can be only the impulse from the water; and therefore the height of the water remaining the same, there must be a larger aperture of the penstock for the discharge of a greater quantity of water in the same time, in order to produce the same effect, as in the overshot, or breast-mill: whence a greater expence of water will be made here than in any other mill, and can only be supplied for a constancy by a river; and where this can be had, the undershot is the easiest, cheapest, and most simple structure a mill is capable of.

Mr. Smeaton has considered the best methods of constructing all these mills from machines and models made on purpose; but, conscious of the inferiority of models to actual practice, did not venture to give his opinion without having seen them actually tried, and the truth of his doctrines established by practice.

Having described the machines and models used for making his experiments, he observes, that, with regard to power, it is most properly measured by the raising of a weight; or, in other words, if the weight raised is multiplied by the height to which it can be raised in a given time, the product is the measure of the power raising it; and, of consequence, all those powers are equal whose products made by such multiplication are equal: for if a power can raise twice the weight to the same height, or the same weight to twice the height, in the same time that another can, the former power will be double the latter; but if a power can only raise half the weight to double the height, or double the weight to half the height, in the same time that another can, the two powers are equal. This, however, must be understood only of a slow and equable motion, without acceleration or retardation; for, if the velocity is either very quickly accelerated or retarded, the vis inertiæ, in our author's opinion, will produce an irregularity.

To compute the effects of water-wheels exactly, it is necessary to know, in the first place, what is the real velocity of the water which impinges on the wheel; 2. The quantity of water expended in a given time; and, 3. How much of the power is lost by the friction of the machinery.

1. With regard to the velocity of the water, Mr. Smeaton determined by experiments with machinery, that with a head of water 15 inches in height, the velocity of the wheel is 8.96 feet in a minute. The area of the head being 105.8 inches; this multiplied by the weight of a cubic inch of water, equal to .579 of an ounce avoirdupoise, gives 61.26 ounces for the weight of as much water as is contained in the head upon one inch in depth; and by further calculations derived from the machinery made use of, he computes that 264.7 pounds of water descend in a minute through the space of 15 inches. The power of the water, therefore, to produce mechanical effects in this case, will be 264.7×15, or 3970. From the result of the experiment, however, it appeared that a vast quantity of the power was lost; the effect being only to raise 9.375 pounds to the height of 135 inches: so that the power was to the effect as 3970 to $9.375 \times 135 = 1266$, or as 10 to 3.18.

This, according to our author, must be considered as the greatest single effect of water upon an undershot-wheel, where the water descends from a height of 15 inches; but as the force of the current is not by any means exhausted, we must consider the true proportion betwixt the power and effect to be that betwixt the quantity of water already mentioned, and the sum of all the effects producible from it. This remainder of power, it is plain, must be equal to that of the velocity of the wheel itself multiplied into the weight of the water. In the present experiment, the circumference of the wheel moved with the velocity of 3.123 feet in a second, which answers to a head of 1.82 inches; and this height being multiplied by 264.7, the quantity of water expended in a minute, gives 481 for the power of the water after it has passed the wheel; and hence the true proportion betwixt the power and the effect will be as 3849 to 1266; or as 11 to 4.

As the wheel revolved 86 times in a minute, the velocity of the water must be equal to 86 circumferences of the wheel; which, according to the dimensions of the apparatus used by Mr. Smeaton, was as 86 to 30, or as 20 to 7. The greatest load with which the wheel would move was 9 lb. 6 oz.; and by 12 lb. it was entirely stopped. Whence our author concludes, that the impulse of the water is more than double of what it ought to be according to theory; but this he accounts for by observing, that in his experiment the wheel was placed not in an open river, where the natural current, after it has communicated its impulse to the float, has room on all sides to escape, as the theory supposes, but in a conduit, to which the float being adapted, the water cannot otherwise escape than by moving along with the wheel. It is observable, that a wheel working in this manner, as soon as the water meets the float, receiving a sudden check, it rises up against the float like a wave against a fixed object; insomuch that, when the sheet of water is not a quarter of an inch thick before the float, yet this sheet will act upon the whole surface of a float whose height is three inches; and, consequently, was the float no higher than the thickness of the sheet of water, as the theory also supposes, a great part of the force would have been lost by the water dashing over the float.

Mr. Smeaton next proceeds to give tables of the velocities of wheels with different heights of water; and from the whole deduces the following conclusions: 1. The virtual or effective head being the same, the effect will be nearly as the quantity of water expended. 2. The expence of water being the same, the effect will be nearly as the height of the virtual, or effective head. 3. The quantity of water expended being the same, the effect is nearly as the square of the velocity. 4. The aperture being the same, the effect will be nearly as the cube of the velocity of the water. Hence, if water passes out of an aperture in the same section, but with different velocities, the expence will be proportional to the velocity; and therefore, if the expence is not proportional to the velocity, the section of the water is not the same. 5. The virtual head, or that from which we are to calculate the power, bears no proportion to the head-water; but when the aperture is larger, or the velocity of the water less, they approach nearer to a coincidence; and consequently, in the large openings of mills and sluices, where great quantities of water are discharged from moderate heads, the head of water, and virtual head determined from the velocity, will nearly agree: which is also confirmed by experience. 6. The most general proportion betwixt the power and effect is that of 10 to 3; the extremes 10 to 3.2, and 10 to 2.8. But it is observable, that where the power is greatest, the second term of the ratio is greatest also: hence we may allow the proportion subsisting in great works to be as three to one. 7. The proportion of velocity between the water and wheel is, in general, about five to two. 8. There is no certain ratio between the load that the wheel will carry at its proper maximum, and what will totally stop it; though the proportions are contained within the limits of 20 to 19, and 20 to 15: but as the effect approaches nearest to the ratio of 20 to 15, or of 4 to 3, when the power is greatest, either by increase of velocity, or quantity of water, this seems to be the most applicable to large works; but as the load that a wheel ought to have, in order to work to the best advantage, can be assigned by knowing the effect that it ought to produce, and the velocity it ought to have in producing it, the exact knowledge of the greatest load it will bear is of the least consequence in practice.

Mr. Smeaton, after having finished his experiments on the undershot-mills, reduced the number of floats, which were originally 24, to 12; which caused a diminution in the effect, by reason that a greater quantity of water escaped between the floats and the floor than before: but on adapting to it a circular sweep of such a length, that one float entered into the curve before the other left it, the effect came so near that of the former, as not to give any hopes of advancing it by increasing the number of floats beyond 24 in this particular wheel.

Our author next proceeds to examine the power of water when acting by its own gravity, in turning an overshot-wheel: "In reasoning without experiment," says he, "one might be led to imagine, that however different the mode of application is, yet that, whenever the same quantity of water descends through the same perpendicular space, the natural effective power would be equal, supposing the machinery free from friction, equally calculated to receive the full effect of the power, and to make the most of it: for, if we suppose the height of a column of water to be 30 inches, and resting upon a base or aperture of one inch square, every cubic inch of water that departs therefrom will acquire the same velocity or momentum from the uniform pressure of 30 cubic inches above it, that one cubic inch let fall from the top will acquire in falling down to the level of the aperture: one would therefore suppose that a cubic inch of water let fall through a space of 30 inches, and there impinging upon another body, would be capable of producing an equal effect by collision, as if the same cubic inch had descended through the same space with a slower motion, and produced its effects gradually. But, however conclusive this reasoning may seem, it will appear in the course of the following deductions, that the effect of the gravity of descending bodies is very different from the effect of the stroke of such as are non-elastic, though generated by an equal mechanical power."

Having made such alterations in his machinery as were necessary for overshot-wheels, our author next gives a table of experiments with the apparatus so altered. In these the head was six inches, and the height of the wheel 24 inches, so that the whole descent was 30 inches; the quantity of water expended in a minute was $96\frac{2}{3}$ pounds; which, multiplied by 30 inches, gives the power $= 2900$: and, after making the proper calculations, the effect was computed at 1914; whence the ratio of the power to it comes to be nearly as 3 to 2. If, however, we compute the power from the height of the wheel only, the power will be to the effect nearly as 5 to 4.

From another set of experiments the following conclusions were deduced:

1. The effective power of the water must be reckoned upon the whole descent; because it must be raised to that height, in order to be able to produce the same effect a second time. The ratios between the powers so estimated, and the effects at a maximum, differ nearly from 4 to 3, and from 4 to 2. Where the heads of water and quantities of it expended are the least, the proportion is nearly from 4 to 3; but where the heads and quantities are greatest, it comes nearer to that of 4 to 2; so that by a medium of the whole the ratio is nearly as 3 to 2. Hence it appears that the effect of overshot-wheels is nearly double to that of undershot ones: the consequence of which is, that non-elastic bodies, when acting by their impulse or collision, communicate only a part of their original impulse, the remainder being spent in changing their figure in consequence of the stroke. The ultimate conclusion is, that the effects as well as the powers are as the quantities of water and perpendicular heights multiplied together respectively.

2. By increasing the head, it does not appear that the effects are at all augmented in proportion; for, by raising it from 3 to 11 inches, the effect was augmented by less than one-seventh of the increase of perpendicular height. Hence it follows, that the higher the wheel is in proportion to the whole descent, the greater will be the effect; because it depends less upon the impulse of the head, and more upon the gravity of the water in the buckets: and if we consider how obliquely the water issuing from the head must strike the buckets, we shall not be at a loss to account for the little advantage that arises from the impulse thereof, and shall immediately see of how little consequence this is to the effect of an overshot-wheel. This, however, as well as other things, must be subject to limitation; for it is necessary that the velocity of the water should be somewhat greater than the wheel, otherwise the latter will not only be retarded by the striking of the buckets against the water, but some of the power will be lost by the dashing of the water over the buckets.

3. To determine the velocity which the circumference of the wheel ought to have, in order to produce the greatest effect, Mr. Smeaton observes, that the more slowly any body descends by the force of gravity, when acting upon any piece of machinery, the more that force will be spent upon it; and consequently the effect will be greater. If a stream of water falls into the bucket of an overshot-wheel, it will be there retained till the wheel discharges it by moving round; and of consequence, the slower the wheel moves, the more water will it receive: so that what is lost in velocity is gained by the greater pressure of water upon the buckets. From the experiments, however, it appears, that when the wheel made about 20 turns in a minute the effect was greatest; when it made only $18\frac{3}{4}$ the motion was irregular; and when loaded so as not to admit its turning 18 times, the wheel was overpowered with the load. When it made 30 turns, the power was diminished by about one-twentieth; and when the number of turns was increased to 40, it was diminished by one-fourth. Hence we see that, in practice, the velocity of the wheel should not be diminished farther than what will procure some solid advantage in point of power; because, cæteris paribus, the buckets must be larger as the motion is slower; and the wheel being more loaded with water, the stress will be proportionably increased upon every part of the work. The best velocity for practice, therefore, will be that when the wheel makes 30 turns in a minute, which is little more than three feet in a second. This velocity is applicable to the highest overshot-wheels as well as the lowest. Experience however determines, that high wheels may deviate farther from this rule before they will lose their power by a given aliquot part of the whole, than low ones can be permitted to do; for a wheel of 24 feet high may move at

the rate of six feet per second, while our author has seen one of 33 feet high move very steadily and well with a velocity of little more than two feet. The reason of this superior velocity in the 24-feet wheel, may probably be owing to the small proportion that the head requisite to give the proper velocity to the wheel bears to the whole height.

4. The maximum load for an overshot-wheel is that which reduces the circumference of the wheel to its proper velocity; which is known by dividing the effect it ought to produce in a given time, by the space intended to be described by the circumference of the wheel in the same time: the quotient will be the resistance overcome at the circumference of the wheel, and is equal to the load required, including the friction and resistance of the machinery.

5. The greatest velocity that an overshot-wheel is capable of, depends jointly upon the diameter, or height of the wheel, and the velocity of falling bodies; for it is plain that the velocity of the circumference can never be greater than to describe a semicircumference, while a body let fall from the top describes the diameter, nor even quite so great; as the difference in point of time must always be in favour of that which falls through the diameter. Thus, supposing the diameter of the wheel to be 16 feet and an inch in diameter, a heavy body would fall through this space in one second; but such a wheel could never arrive at this velocity, or make one turn in two seconds, nor could an overshot-wheel ever come near it: because, after it has acquired a certain velocity, great part of the water is prevented from entering the buckets, and part is thrown out again by the centrifugal force; and as these circumstances have a considerable dependance upon the form of the buckets, it is impossible to lay down any general rule for the velocity of this kind of wheels.

6. Though in theory we may suppose a wheel to be made capable of overcoming any resistance whatever, yet as, in practice, it is necessary to make the wheel and buckets of some certain and determinate size, we always find that the wheel will be stopped by such a weight as is equal to the effort of the water in all the buckets of a semicircumference put together. This may be determined from the structure of the buckets themselves; but, in practice, an overshot-wheel becomes unserviceable long before this time: for when it meets with such an obstacle as diminishes its velocity to a certain degree its motion becomes irregular; but this never happens till the velocity of the circumference is less than the two feet per second, when the resistance is equable.

7. From the above observations we may easily deduce the force of water upon breast-wheels, &c. But, in general, all kinds of wheels where the water cannot descend through a given space unless the wheel moves with it, are to be considered as overshot-wheels; and those which receive the impulse or shock of the water, whether in an horizontal, oblique, or perpendicular direction, are to be considered as undershots. Hence in a wheel in which the water strikes at a certain point below the surface of the head, and after that descends in the arch of a circle, pressing by its gravity upon the wheel, the effect of such a wheel will be equal to that of an undershot whose head is equal to the difference of level between the surface of the water in the reservoir and the point where it strikes the wheel, added to that of an overshot whose height is equal to the difference of level between the point where it strikes the wheel and the level of the tail-water.

In the 66th volume of the Transactions our author considers some of the causes which have produced disagreements and disputes among mathematicians upon this subject. He observes, that soon after sir Isaac Newton had given his definition, "that the quantity of motion is the measure of the same, arising from the velocity and quantity of matter conjointly," it was controverted by his contemporary philosophers. They maintained, that the measure of the quantity of motion should be estimated by taking the quantity of matter and the square of the velocity conjointly. On this subject he remarks, that from equal impelling powers acting for equal intervals of time, equal augmentations of velocity are acquired by given bodies when they are not resisted by a medium. Thus a body descending one second by the force of gravity, passes through a space of 16 feet and an inch; but at the end of that time it has acquired a velocity of 32 ft. 2 inc. in a second: at the end of 2 sec. it has acquired one that would carry it through 64 feet 4 inches in a second. If, therefore, in consequence of this equal increase of velocity, we define this to be a double quantity of motion generated in a given time in a certain quantity of matter, we come near to sir Isaac's definition: but in trying experiments upon the effects of bodies, it appears, that when a body is put in motion, by whatever cause, the impression it will make upon an uniformly resisting medium, or upon uniformly yielding substances, will be as the mass of matter of the moving body multiplied by the square of its velocity. The question therefore properly is, whether those terms, the quantity of motion, the momenta, or forces of bodies in motion, are to be esteemed equal, double, or triple, when they have been generated by an equable impulse acting for an equal, double, or triple time? or that it should be measured by the effects being equal, double, or triple, in overcoming resistances before a body in motion can be stopped? For, according to the meaning we put upon these words, the momenta of equal bodies will be as the velocities or squares of the velocities of the moving bodies.

Though by a proper attention to the terms employed, however, we shall find both these doctrines to be true; it is certain that some of the most celebrated writers upon mechanics have fallen into errors by neglecting to attend to the meaning of the terms they make use of. Desaguliers, for instance, after having been at pains to show that the dispute, which in his time had subsisted for 50 years, was a dispute merely about words, tells us, that both opinions may be easily reconciled in the following case, viz. that the wheel of an undershot water-mill is capable of doing quadruple work when the velocity of the water is doubled, instead of double work only: "For," says he, "the adjutage being the same, we find, that as the water's velocity is double, there are twice the number of particles that issue out, and therefore the ladle-board is struck by twice the matter; which matter moving with twice the velocity that it had in the first case, the whole effect must be quadruple, though the instantaneous stroke of each particle is increased only in a simple proportion of the velocity." In another place the same author tells us, that though "the knowledge of the foregoing particulars is absolutely necessary for setting an undershot-wheel to work, yet the advantage to be reaped from it would still be guess-work, and we should be at a loss to find out the utmost that it could perform, had it not been for an ingenious proposition of that excellent mechanic, M. Parent, of the royal academy of sciences, who has shewed, that an undershot-wheel can do the most work when its velocity is equal to the third part of that of the water; because then two-thirds of the water are employed in driving the wheel, with a force proportionable to the square of the velocity. By multiplying the surface of the adjutage or opening by the height of the water, we shall have the column of water that moves the wheel. The wheel thus moved will sustain on the opposite side only four-ninths of that weight which will keep it in equilibrio; but what it can move with the velocity it has, is only one-third of the equilibrium." This conclusion is likewise adopted by Mr. Maclaurin.

Mr. Smeaton, in the year 1759, instituted another set of experiments; the immediate object of which was, to determine what proportion or quantity of mechanical power is expended in giving the same body different degrees of velocity. Having constructed a proper apparatus for the purpose, and with it made a number of experiments, he concludes, "that time, properly speaking, has nothing to do with the production of mechanical effects, otherwise than as by equally flowing it becomes a common measure; so that, whatever mechanical effect is found to be produced in a given time, the uniform continuance of the action of the same mechanical power will, in a double time, produce twice that effect. A mechanical power, therefore, properly speaking, is measured by the whole of its mechanical effect produced, whether that effect be produced in a greater or less time: thus, having treasured up 1000 tuns of water, which I can let out upon the overshot-wheel of a mill, and descending through a perpendicular of 20 feet; this power, applied in a proper manner, will grind a certain quantity of corn in an hour: but, supposing the mill to be capable of receiving a greater impulse with as great advantage as a less; then, if the corn is let out twice as fast, the same quantity of corn will be ground in half an hour, the whole of the water being likewise expended in that time. What time has therefore to do in the case is this: Let the rate of doing the business, or producing the effect, be what it will; if this rate is uniform, when I have found by experiment what is done in a given time, then, proceeding at the same rate, twice the effect will be produced in twice the time; on supposition that I have a supply of mechanic power to go on with. Thus, 1000 tuns of water descending through 20 feet perpendicular, being, as has been shewn, a given mechanic power, let it be expended at what rate it will; if, when this is expended, we are to wait another hour till an equal quantity can be procured, then we can only expend 12 such quantities in 24 hours. But if, while the thousand tuns of water are expending in one hour, the same quantity is renewed, we can then expend 24 such in the 24 hours, or go on without intermission. The product or effect will then be in proportion to time, which is the common measure; but the quantity of mechanic power arising from the flow of the two rivers, compared by taking an equal portion of time, is double in the one to the other; though each has a mill that, when going, will grind an equal quantity of corn in an hour."

The following is a description of a corn-mill of the most common sort. See Plate, Mills.

AB (fig. 1) is the water-wheel, which is generally from 18 to 24 feet in diameter, reckoned from the outermost edge of any float-board at A, to that of the opposite one at B. The water striking on the floats of this wheel drives it round, and gives motion to the mill. The wheel is fixed upon a very strong axis or shaft, C, one end of which rests on D, and the other on E, within the mill-house.

On this shaft, or axis, and within the mill-house, is a wheel F, about eight or nine feet in diameter, having cogs all round, which work in the upright staves, or rounds, of a trundle G. This trundle is fixed upon a strong iron axis, called the spindle, the lower end of which turns in a brass foot fixed at H, in a horizontal beam H, called the bridge-tree; and the upper end of the spindle turns in a wooden bush fixed into the nether mill-stone, which lies upon beams in the floor I. The top of the spindle above the bush is square, and goes into a square hole in a strong iron cross, *abcd* (fig. 2), called the rynd; under which, and close to the bush, is a round piece of thick leather upon the spindle, which it turns round at the same time as it does the rynd.

The rynd is let into grooves in the under surface of the running mill-stone K, and so turns it round in the same time that the trundle G is turned round by the cog-wheel F. This mill-stone has a large hole quite through its middle, called the eye of the stone, through which the middle part of the rynd and upper end of the spindle may be seen; whilst the four ends of the rynd lie below the stone in their grooves.

One end of the bridge-tree, which supports the spindle, rests upon the wall, whilst the other is let into a beam, called the brayer, LM.

The brayer rests in a mortice at L; and the other end M hangs by a strong iron rod N, which goes through the floor I, and has a screw-nut on its top at O; by the turning of which nut, the end M of the brayer is raised or depressed at pleasure; and consequently the bridge-tree and the upper mill-stone. By this means the upper mill-stone may be set as close to the under one, or raised as high from it, as the miller pleases.

The nearer the mill-stones are to each other, the finer the corn is ground; and the more remote from one another, the coarser.

The upper mill-stone is inclosed in a round box, which does not touch it any where, and is about an inch distant from its edge all round. On the top of this box stands a frame for holding the hopper P, to which is hung the shoe Q, by two lines fastened to the hinder part of it, fixed upon hooks in the hopper, and by one end of the string R fastened to the fore part of it; the other end being twisted round the pin S. As the pin is turned one way, the string draws up the shoe closer to the hopper, and so lessens the aperture between them; and as the pin is turned the other way, it lets down the shoe, and enlarges the aperture.

If the shoe is drawn up quite to the hopper, no corn can fall from the hopper into the mill: if it is let down a little, some will fall; and the quantity will be more or less, according as the shoe is more or less let down; for the hopper is open at bottom, and there is a hole in the bottom of the shoe, not directly under the bottom of the hopper, but nearer to the lowest end of the shoe, over the middle eye of the mill-stone.

There is a square hole in the top of the spindle, in which is put the feeder F (fig. 2); this feeder, as the spindle turns round, jogs the shoe three times in each revolution, and so causes the corn to run constantly down from the hopper through the shoe into the eye of the mill-stone, where it falls upon the top of the rynd, and is, by the motion of the rynd, and the leather under it, thrown below the upper stone, and ground between it and the lower one. The violent motion of the stone creates a centrifugal force in the corn going round with it, by which means it gets farther and farther from the centre, as in a spiral, in every revolution, until it is quite thrown out; and being then ground, it falls through a spout, called the mill-eye, into a trough placed to receive it.

When the mill is fed too fast the corn bears up the stone, and is ground too coarse; and, besides, it clogs the mill, so as to make it go too slow. When the mill is too slowly fed, it goes too fast; and the stones, by their attrition, are apt to strike fire. Both these inconveniences are avoided by turning the pin S backward or forward, which draws up or lets down the shoe; and thus regulates the feeding, as the miller sees convenient.

The heavier the running mill-stone is, and the greater the quantity of water that falls upon the wheel, the faster will the mill bear to be fed, and consequently it will grind the more: and, on the contrary, the lighter the stone, and the less the quantity of water, so much the slower must the feeding be. But when the stone is considerably worn, and become light, the mill must be fed slowly at any rate; otherwise the stone will be too much borne up by the corn under it, which will make the meal coarse.

The quantity of power sufficient to turn a heavy mill-stone, is but very little more than what is necessary to turn a light one; for as it is supported upon the spindle by the bridge-tree, and the end of the spindle that turns in the brass foot therein being but small, the difference arising from the weight is but very inconsiderable in its action against the power or force of the water; and, besides, a heavy stone has the same advantage as a heavy fly, namely, that it regulates the motion much better than a light one.

The centrifugal force carrying the corn towards the circumference, it is natural it should be crushed, when it comes to a place where the interval between the two mill-stones is less than its thickness; yet the upper mill-stone being supported on a point which it can never quit, it does not so clearly appear why it should produce a greater effect when it is heavy than when it is light; since, if it were equally distant from the nether mill-stone, it could only be capable of a limited impression. But as experience proves that this is really the case, it is necessary to discover the cause. The spindle of the mill-stone being supported by a horizontal piece of timber, about nine or ten feet long, resting only on both its ends, by the elasticity of this piece, the upper mill-stone is allowed a vertical motion, playing up and down; by which movement, the heavier the stones are, the more forcibly is the corn wedged in between them.

In order to cut and grind the corn, both the upper and under mill-stones have channels or furrows cut into them, proceeding obliquely from the centre to the circumference. And these furrows are cut perpendicularly on one side, and obliquely on the other, which gives each furrow a sharp edge; and in the two stones they come against one another, like the edges of a pair of scissars; and so cut the corn, to make it grind the easier, when it falls upon the places between the furrows. These are cut the same way in both stones, when they lie upon their backs, which makes them run crossways to each other when the upper stone is inverted, by turning its furrowed surface towards that of the lower; for if the furrows of both stones lay the same way, a great deal of the corn would be driven onward in the lower furrows, and so come out from between the stones, without being either cut or bruised.

The grinding surface of the under stone is a little convex from the edge to the centre, and that of the upper stone a little concave; so that they are farthest from one another in the middle, and approach gradually nearer towards the edges. By this means the corn, at its first entrance between the stones, is only bruised; but as it goes farther on towards the circumference or edge, it is cut smaller and smaller; and, at last, finely ground, just before it comes out from between them.

When the furrows become blunt and shallow by wearing, the running-stone must be taken up, and both stones new drest with a chisel and hammer; and every time the stone is taken up there must be some tallow put round the spindle upon the bush, which will soon be melted by the heat the spindle acquires from its turning and rubbing against the bush, and so will get in betwixt them; otherwise the bush would take fire in a very little time.

The bush must embrace the spindle quite close, to prevent any shake in the motion, which would make some parts of the stones grate and fire against each other; whilst the other parts of them would be too far asunder, and by that means spoil the meal.

Whenever the spindle wears the bush, so as to begin to shake in it, the stone must be taken up, and a chisel driven into several parts of the bush; and when it is taken out, wooden wedges must be forced into the holes; by which means the bush will be made to embrace the spindle again, close all round. In doing this, great care must be taken to drive equal wedges into the bush on opposite sides of the spindle; otherwise it will be thrown out of the perpendicular, and so hinder the upper stone from being set parallel to the under one, which is absolutely necessary for making good work. When any accident of this kind happens, the perpendicular position of the spindle must be restored, by adjusting the bridge-tree with proper wedges put between it and the brayer.

It often happens that the rynd is a little wrenched in laying down the upper stone upon it, or is made to sink a little lower on one side of the spindle than on the other; and this will cause one edge of the upper stone to drag all round upon the other, while the opposite edge will not touch. But this is easily set to rights, by raising the stone a little with the lever, and putting bits of paper, cards, or thin chips, between the rynd and the stone.

A less quantity of water will turn an overshot-mill (where the wheel has buckets instead of float-boards) than a breast-mill, where the fall of water seldom exceeds half the height of the wheel; so that where there is but a small quantity of water, and a fall great enough for the wheel to lie under it, the bucket, or overshot, wheel, is always used: but where there is a large body of water with a little fall, the breast, or float-board, wheel must be used. Where the water runs only upon a small declivity, it can act but slowly upon the under part of the wheel; in which case the motion of the wheel will be slow: and therefore the floats ought to be very long, though not high, that a large body of water may act upon them; so that what is wanting in velocity may be made up in power; and then the cog-wheel may have a greater number of cogs, in proportion to the rounds in the trundle, in order to give the mill-stone a sufficient degree of velocity.

It was the opinion of Smeaton, that the powers necessary to produce the same effect on an undershot-wheel, a breast-wheel, and an overshot-wheel, must be to each other as the numbers 2.4, 1.75, and 1.

Practical rules for the construction of mills.—1. Measure the perpendicular height of the fall of water, in feet, above that part of the wheel on which the water begins to act, and call that the height of the fall.

2. Multiply this constant number 64.2882 by the height of the fall in feet, and the square root of the product will be the velocity of the water at the bottom of the fall, or the number of feet that the water there moves per second.

3. Divide the velocity of the water by three, and the quotient will be the velocity of the float-boards of the wheel, or the number of feet they must each go through in a second, when the water acts upon them so as to have the greatest power to turn the mill.

4. Divide the circumference of the wheel in feet by the velocity of its floats in feet per second, and the quotient will be the number of seconds in which the wheel turns round.

5. By this last number of seconds divide 60, and the quotient will be the number of turns of the wheel in a minute.

6. Divide 120 (the number of revolutions a mill stone four feet and a half diameter ought to have in a minute) by the number of turns of the wheel in a minute, and the quotient will be the number of turns the mill-stone ought to have for one turn of the wheel.

7. Then, as the number of turns of the wheel in a minute, is to the number of turns of the mill-stone in a minute, so must the number of staves in the trundle, be to the number of cogs in the wheel, in the nearest whole numbers that can be found.

By these rules the following table is calculated to a water-wheel 18 feet diameter, which may be a good size in general.

THE MILL-WRIGHT'S TABLE.

Height of the fall of water.	Velocity of the fall of water per second.		Velocity of the wheel per second.		Revolutions of the wheel per minute.		Revolutions of the mill-stone for one of the wheels.		Cogs in the wheel, and staves in the trundle.		Revolutions of the mill-stone per minute, by these staves and cogs.	
Feet.	Feet.	100 parts of a foot.	Feet.	100 parts of a foot.	Revolutions.	100 parts of a rev.	Revolutions.	100 parts of a rev.	Cogs.	Staves.	Revolutions.	100 parts of a rev.

To construct a mill by this table, find the height of the fall of water in the first column, and against that height, in the sixth column, you have the number of cogs in the wheel, and staves in the trundle, for causing the mill-stone, four feet six inches diameter, to make about 120 revolutions in a minute, as near as possible, when the wheel goes with one-third part of the velocity of the water. And it appears by the 7th column, that the number of cogs in the wheel, and staves in the trundle, are so near the truth for the required purpose, that the least number of revolutions of the mill-stone in a minute is 118, and the greatest number never exceeds 121; which is according to the speed of some of the best mills.

One of the most usual communications of motion in machinery, is by means of toothed wheels acting on each other. It is of the greatest consequence to have the teeth so formed, that the pressure by which one of them urges the other round its axis is constantly the same. This is by no means the case when the common construction of a spur-wheel, acting in the cylindrical staves of a lantern, or trundle, is used. The ends of teeth should never be formed of parts of circles, but of a particular curve, called the epicycloid, which is formed by moving the circle, called the generating circle, round the circumference of another circle, while it turns also round its own centre; then any point will describe an epicycloid.

Emerson observes, that the teeth of wheels ought not to act upon each other before they arrive at the line which joins their centres; and though the inner or under sides of the teeth may be of any form, yet it is better to make both sides alike, which will serve to make the wheel turn backwards. The more teeth that work together the better; at least one tooth should always begin before the other has done working. The teeth ought to be so disposed as not to trouble or hinder one another before they begin to work.

If the cogs of a wheel and rounds of a trundle could be put in as exactly as the teeth are cut in the wheels and pinions of a clock, then the trundle might divide the wheel exactly, that is to say, the trundle might make a given number of revolutions for one of the wheel, without a fraction. But as any exact number is not necessary in mill-work, and the cogs and rounds cannot be set in so truly as to make all the intervals between them equal, a skilful mill-wright will always give the wheel what he calls a hunting-cog; that is, one more than what will answer to an exact division of the wheel by the trundle. And then as every cog comes to the trundle, it will take the next staff, or round, behind the one which it took in the former revolution; and by that means will wear all the parts of the cogs and rounds which work upon one another equally, and to equal distances from one another, in a little time. See Flour-mill.

Mills, Bark, like most other mills, are worked sometimes by means of horses, at others by water, and at others by wind. One of the best mills we have seen described for these purposes is that invented by Mr. Bagnall, of Worsley, in Lancashire: this machine will serve not only to chop bark, to grind, to riddle, and pound it, but to beam, or work green hides and skins out of the mastering, or drench, and make them ready for the ouse, or bark-liquor; to beam sheepskins and other skins for the skinner's use; and to scour and take off the bloom from tanned leather, when in the currying state. The nature and connection of the different parts of this contrivance may be understood from the figures and following description:

Fig. 3 is a horizontal plan of the mill. Fig. 4, a longitudinal section of it. Fig. 5, a transverse section of it.

A, the water-wheel, by which the whole machinery is worked.

B, the shafts.

C, the pit-wheel, which is fixed on the water-wheel shaft B, and turns the upright shaft E, by the wheel F, and works the cutters and hammer by tapets.

D, the spur and bevil-wheel at the top of the upright shafts.

E, the upright shaft.

F, the crown-wheel, which works in the pit-wheel C.

G, the spur-nut to turn the stones I.

P, the beam, with knives or cutters fixed at the end to chop or cut the bark; which bark is to be put upon the cutters or grating *i*, on which the beam is to fall.

Q, the tryal that receives the bark from the cutters *i*, and conveys it into the hopper H, by which it descends through the shoe J to the stones I, where it is ground.

K, the spout, which receives the bark from the stones, and conveys it into the tryal L; which tryal is wired to sift or dress the bark, as it descends from the stones I.

M, the trough to receive the bark that passes through the tryal L.

R, the hammer, to crush or bruise the bark that falls into the dish S, which said dish is on the incline, so that the hammer keeps forcing it out of the lower side of the said dish when bruised.

k, a trough to receive the dust and moss that passes through the tryal Q.

T, the bevil-wheel, that works in the wheel D, which works the beam-knife by a crank V, at the end of the shaft *u*.

W, the penetrating rod, which leads from the crank V to the start *x*.

x, the start, which has several holes in it to lengthen or shorten the stroke of the beam-knife.

y, the shaft, to which the slide rods *h*, *h*, are fixed by the starts *n*, *n*.

h, the slide-rod, on which the knife *f* is fixed; which knife is to work the hides, &c. On the knife are two springs *a*, *a*, to let it have a little play as it makes its stroke backwards and forwards, so that it may not scratch or damage the hides, &c.

z, is a catch in a slide-rod *h*, which catches on the arch-head *e*; and the said arch-head conveys the knife back without touching the hide, and then falls back to receive the catch again.

l, the roller to take up the slide-rod *h*, while the hides are shifting on the beam *b*, by pulling at the handle *m*.

b, the beam to work the hides, &c. on. Each beam has four wheels *p*, *p*, working in a trough-road *g*, *g*, and removed by the levers *c*, *c*. When the knife has worked the hide, &c. sufficiently in one part, the beam is then shifted by the lever *c* as far as is wanted.

d, a press, at the upper end of the beam, to hold the hide fast on the beam while working.

e an arch-head, on which the slide-rod *h* catches.

f, the knife fixed on the slide-rod *h*, to work the hides, &c.

i, cutters, or grating, to receive the bark for chopping.

The beam P, with knives or cutters, may either be worked by tapers, as described, or by the bevil-wheel T, with a crank, as V, to cut the same as shears.

The knife *f* is fixed at the bottom of the start, which is fixed on the slide-rod *h*; the bottom of the start is split open to admit the knife, the width of one foot; the knife should have a gudgeon at each end, to fix in the open part of the start; and the two springs *a*, *a*, prevent the knife from giving too much way when working; the knife should be one foot long, and four or five inches broad.

The arch-head *e* will shift nearer to, or further from, the beam *h*; and will be fixed so as to carry the knife back as far as is wanted, or it may be taken away till wanted.

The roller *l* is taken up by pulling at the handle *m*, which takes up the slide-rod so high as to give head-room under the beam-knife. The handle may be hung upon a hook for that purpose. The slide-rod will keep running upon the roller all the time the hide is shifting; and when the hide is fixed the knife is put on the beam again by letting it down by the handle *m*. There may be two or more knives at work on one beam at the same time, by having different slide-rods. There should be two beams, so that the workmen could be shifting one hide, &c. while the other was working. The beam must be flat, and a little on the incline. As to the breadth it does not matter; the broader it is the less shifting of the hides will be wanted, as the lever *c* will shift them as far as the width of the hide, if required. Mr. Bagnall has formed a kind of press *d*, to let down, by a lever, to hold the hide fast on each side of the knife, if required, so that it will suffer the knife to make its back stroke without pulling the hide up as it comes back. The slide-rod may be weighted, to cause the knife to lay stress on the hide, &c. according to the kind and condition of the goods to be worked.

Hides and skins for the skinner's use are worked in the same way as for the tanners.

Scouring of tanned leather for the currier's use will be done on the beam, the same as working green hides. It is only taking the knife away, and fixing a stone in the same manner as the knife by the said joint, and to have a brush fixed to go either before or after the stone. The leather will be better secured this way than by hand, and much sooner.

The whole machinery may be worked by water, wind, steam, or any other power. And that part of the machinery which relates to the beaming part of the hides may be fixed to any horse bark-mill, or may be worked by a horse, or other power, separately. See Gregory's valuable work on Mechanics, to which we have been indebted for this part of the present article and some others, particularly the table of specific gravities in vol. 1.

The following is a description of Mr. Terry's improved mill for grinding hard substances: Fig. 6, A, is the hopper; B, a spiral wire, in the form of a reversed cone, to regulate the delivery of the articles to be ground; C, an inclined iron plate, hung upon a pin on its higher end: the lower end rests on the grooved axis D, and agitates the wire B; D is the grinding cylinder, which acts against the channeled iron plate E; F, a screw on the side of the mill, by means of which the iron plate E is brought nearer to, or removed farther from, the axis D, according as the article is wanted finer or coarser; G, the handle by which motion is given to the axis; H, the tube whence the articles, when ground, are received.

Mill *for grinding colours*. A machine of this kind was invented a few years ago by Mr. Rawlinson, for which he was presented with the gold medal by the society for the encouragement of arts, manufactures, &c. the description of which is as follows:

A, fig. 7, is the roller, or cylinder, made of marble; B is the concave muller, covering one-third of the roller of the same marble, and is fixed in a wooden frame *b*, which is hung to the frame E, at *ii*. C is a piece of iron about an inch broad, to keep the muller steady, and is fixed to the frame with a joint at *f*. The small binding screw, with the fly-nut that passes through the centre of the iron plate at *c*, is for the purpose of laying more pressure on the muller, if required, and to keep it more steady. D is a taker-off, made of a clock-spring, about half an inch broad, and fixed to a similar frame-saw, in an iron frame K, in an inclined position to the roller, and turning on pivots at *dd*. G is a slide-board, to draw out occasionally, to clean, and to sustain the plate H, to catch the colour on as it falls from the taker-off. F is a drawer, for the purpose of containing curriers' shavings, which are the best things for cleaning paint-mills.

We shall now add an account of an improved mill for grinding indigo, or other dry colours. L, fig. 8, represents a mortar made of hard marble, or hard stone; M, a muller, nearly in the form of a pear, in the upper part of which an iron axis is firmly fixed; which axis, at the parts NN, turns in grooves or slits, cut in two pieces of oak, projecting horizontally from a wall; and when the axis is at work, it is secured in the grooves by iron pins, OO. P, the handle, which forms part of the axis, and by which the grinder is worked. Q, the wall, in which the oak pieces, NN, are fixed. R, a weight, which may occasionally be added, if more power is wanted. Fig. 9 shews the muller, with its axis, separate from the other machinery; its bottom should be made to fit the mortar. S is a groove cut through the stone. The indigo, &c. to be ground, is thrown above the muller into the mortar; on turning the handle the lumps fall into the groove cut through the muller, and are thence drawn under its action, and driven to the outer edge within the mortar, from whence the coarser particles again fall into the groove of the muller, and are again ground under it. A wooden cover, in two halves, with a hole for the axis, is usually placed upon the mortar, during the operation, to prevent loss of colour, or bad effect to the operator.

Mill, Foot, is a mill for grinding corn or any other substance, moved by the pressure of the feet of men or animals. In some foot-mills a horse or an ox is fixed to a stall upon a floor above a vertical wheel; and a hole is made in the floor in the place where the hind feet of the animal should stand; thus admitting those feet to press upon the rim of a wheel, and cause the wheel to turn upon its axle, and give motion to the whole mill. But in this kind of machine the animal will be obliged very unnaturally to move his hind feet while his fore feet will be at rest; and further, the motive force being applied near the vertex of the wheel will act but with little advantage; and the work done will be comparatively trifling.

Hand-Mill, or *horse-mill*, is that worked by the hand, or by horses, &c. There is a long beam or lever for moving it, so attached that it may receive many men or horses, to drive several mills at once. There is the cog-wheel, placed horizontally, with pins fixed, not on its plane, but on the outside, at the circumference of the joints. There are also the trundle-head, the support, the iron axis, and the drum where the mill-stones are inclosed.

MILLENARIANS, or Chiliasts, a name given to those who, in the primitive ages, believed that the saints will one day reign on earth with Jesus Christ a thousand years.

MILLEPES. See Oniscus.

MILLEPORA. See Madrepore, Zoophites, and Plate Nat. Hist. figs. 266, 267.

MILLERIA, a genus of the syngenesia polygamia necessaria class of plants, the compound flower of which is radiated; there is scarcely any visible receptacle of the seeds, which are single after each particular flower, and have no pappus or down. There are three species.

MILLET. See Millium, and Panicum.

Millet-grass. See Milium.

MILLING. See Fulling.

MIMOSA, the *sensitive plant*, a genus of the polygamia order, in the monœcia class of plants, and in the natural method ranking under the 33d order, lomentaceæ. The hermaphrodite calyx is quinquedentate; the corolla quinquefid; there are five or more stamina, one pistil, and a legumen; the male calyx is quinquedentate; the corolla quinquefid, with five, ten, or more stamina.

The name mimosa signifies "mimic;" and is given to this genus on account of the sensibility of the leaves, which, by their motion, mimic or imitate the motion of animals. This genus comprises 85 different species, all natives of warm climates. Of the sorts cultivated here in our stoves, &c. some are of the shrub and tree kind, and two or three are herbaceous perennials and annuals. The sensitive kinds are exceedingly curious plants in the very singular circumstance of their leaves receding rapidly from the touch, and running up close together; and in some sorts the footstalks and all are affected, so as instantly to fall downward as if fastened by hinges, which last are called humble sensitives. They have all winged leaves, each wing consisting of many small pinnæ. The following are the most remarkable:

1. The sensitiva, or common sensitive humble plant, rises with an under-shrubby prickly stem, branching six or eight feet high, armed with crooked spines; conjugated, pinnated leaves, with bijugated partial lobes or wings, having the inner ones the least, each leaf on a long footstalk; and at the sides and ends of the branches many purple flowers in roundish heads; succeeded by broad, flat, jointed pods, in radiated clusters. This is somewhat of the humble sensitive kind; the leaves, footstalks and all, receding from the touch, though not with such facility as in some of the following sorts.

2. The pudica, or bashful humble plant, rises with an under-shrubby, delineated, prickly stem, branching two or three feet round, armed with hairy spines. This is truly of the humble sensitive kind; for by the least touch the leaves instantly recede, contract, close, and, together with the footstalk, quickly decline downward, as if ashamed at the approach of the hand.

3. The pernambuca, or pernambuca slothful mimosa, recedes very slowly from the touch, only contracting its pinnæ a little when smartly touched: hence the name slothful mimosa.

4. The asperata, or Panama sensitive plant, seldom rises above three feet in height; but its slender branches extend considerably on the neighbouring bushes. It is armed with crooked sharp spines, so thickly set on the trunk, branches, and leaves, that there is no touching it with safety. But the plant has a beautiful appearance; the flowers are yellow and globular, growing at the extremity of the branches. The pods are hairy, brown, and jointed; each containing a small, flat, and brown seed. The leaves are numerous, small, and winged: next to those of the mimosa pudica they are the most irritable; contracting with the least touch, and remaining so for several minutes after. This species would form a good hedge or fence round a garden.

5. The punctata, or punctated sensitive mimosa, rises with a shrubby, upright, taper, spotted, unarmed stem, branching erectly five or six feet high; bipinnated leaves, of four or five pair of long winged folioles, having each about 20 pair of pinnæ; and at the axillas and termination of the branches oblong spikes of yellowish decandrious flowers, the inferior ones castrated; succeeded above by oblong seed-pods. This sort, tho' naturally shrubby and perennial in its native soil, yet in this country sometimes decays in winter. It is only sensitive in the foliola, but quick in the motion.

6. The viva, lively mimosa, or smallest sensitive weed, has many creeping roots, and spreads itself so as to cover large spots of ground. It rises at most to two inches, and has winged leaves, with numerous small pinnæ. The flower is globular, of a blueish colour, and grows in clusters from the axillæ: these are followed by little, short, hairy pods, containing smooth shining seeds. This is the most sensible of all the mimosas, the pudica not excepted. By running a stick over the plant, a person may write his name, and it will remain visible for ten minutes.

7. The quadrivalvis, perennial, or quadrivalve humble mimosa, has herbaceous, slender, quadrangular, prickly stems, branching and spreading all around, armed with recurved spines; bipinnated leaves of two or three pair of winged lobes, having each many pinnæ; and at the axillas globular heads of purple flowers, succeeded by quadrivalvular pods. This is of the humble sensitive kind, both leaves and footstalks receding from the touch.

8. The plena, annual, or double-flowered sensitive mimosa, rises with an herbaceous, erect, round, unarmed stem, closely branching and spreading every way, three or four feet high; bipinnated leaves of four or five pair of winged lobes, of many pairs of pinnæ; and at the axillas and termination of the branches, spikes of yellow pentandrous flowers, the lower ones double, succeeded by short broad pods. This annual is only sensitive in the foliola, but extremely sensible of the touch or air.

9. The cornigera, or horned Mexican mimosa, commonly called great horned acacia, has a shrubby, upright, deformed stem, branching irregularly, armed with very large horn-like white spines, by pairs, connected at the base; bipinnated leaves thinly placed; and flowers growing in spikes. This species is esteemed a curiosity for the oddity of its large spines, resembling the horns of animals, and which are often variously wreathed, twisted, and contorted.

10. The farnesiana, or fragrant acacia, grows in woodlands and waste lands in most parts of Jamaica; rising to 25 or 30 feet, with suitable thickness. Formerly the flowers of this tree were used as an ingredient in the theriaca andromachi of the old dispensatories. The tree is sometimes planted for a hedge or fence round inclosures; and the timber, though small, is useful in rural economy.

11. The arborea, or wild tamarind-tree, is common in all the woodlands, and especially near where settlements have been made, in Jamaica. It rises to a considerable height, and is proportionably thick. The timber is excellent, and serves many purposes in rural economy: it is of the colour of cedar, pretty hard, and takes a good polish. The leaves are numerous; the flowers globular and white. The pods are about a foot in length, of a fine scarlet colour; when they are ripe they open and become twisted. The seeds then appear.

12. The latifolia, shag-bark, or white wild tamarind. This excellent timber-tree is very common in Jamaica, and rises to a moderate height and good thickness. The trunk is rough and scaly: the leaves are numerous, of a rhomboidal figure, and yellowish cast. The flower-spikes are from the axillæ; their colour is yellow. The seed-vessels are flat, jointed, and twisted. The seeds are of the bigness of a vetch, white, and finely streaked with blue.

13. The lebeck, or ebony-tree. This is a native of the East Indies, but raised from seeds in Jamaica and St. Vincent's.

14. The scandens, cacoons, or mafootoo wyth, is frequent in all the upland valleys and woodlands on the north side of Jamaica. It climbs up the tallest trees, and spreads itself in every direction by means of its cirrhi, or claspers, so as to form a complete arbour, and to cover the space of an English acre from one root. This circumstance has a bad effect on the trees or bushes so shaded; light, air, and rain, (so necessary for all plants,) being shut out, the leaves drop off, the tree gradually rots, and the limbs fall down by the weight of this parasite.

The roots of this plant run superficially under the ground or herbage. The trunk is seldom thicker than a man's thigh; and sends off many branches, with numerous shining green leaves, each of which terminates in a tendril or clasper, that serves to fasten it to trees or bushes. The flower-spikes are from the axillæ: they are slender, and the florets on them small and numerous. The pod is perhaps the largest and longest in the world; being sometimes eight or nine feet in length, five inches broad, jointed, and containing 10 or 15 seeds. These seeds are brown, shining, flattened, and very hard, and called cacoons. They are the same as mentioned in the Philosophical Transactions, No. 222, page 298, by sir Hans Sloane, as being thrown ashore on the Hebrides and Orkneys.

This bean, after being long soaked in water, is boiled and eaten by some negroes; but, in general, there seems to be no other use made of it than as a sort of snuff-box.

15. The catechu, according to Mr. Ker (Med. Obs. and Inquir. vol. v. p. 151, &c.), grows only to 12 feet in height, and to one foot in diameter; it is covered with a thick, rough, brown bark, and towards the top divides into many close branches: the leaves are bipinnated, or doubly winged, and are placed alternately upon the younger branches: the partial pinnæ are nearly two inches long, and are commonly from 15 to 30 pair, having full glands inserted between the pinnæ: each wing is usually furnished with about 40 pair of pinnulæ, or linear lobes, beset with short hairs: the spines are short. From this tree, which grows plentifully on the mountainous parts of Indostan, where it flowers in June, is produced the officinal drug long known in Europe by the name of terra japonica.

16. The nilotica, or true Egyptian acacia, rises to a greater height than the preceding. The fruit is a long pod, resembling that of the lupin, and contains many flattish brown seeds. It is a native of Arabia and Egypt, and flowers in July. Although the mimosa nilotica grows in great abundance over the vast extent of Africa, yet gum arabic is produced chiefly by those trees which are situated near the equatorial regions; and we are told that in Lower Egypt the solar heat is never sufficiently intense for this purpose. The gum exudes in a liquid state from the bark of the trunk and branches of the tree, in a similar manner to the gum which is often produced upon the cherry-trees, &c. in this country; and by exposure to the air it soon acquires solidity and hardness. In Senegal the gum begins to flow when the tree first opens its flowers; and continues during the rainy season till the month of December, when it is collected for the first time. Another collection of the gum is made in the month of March, from incisions in the bark, which the extreme dryness of the air at that time is said to render necessary. Gum arabic is now usually imported into England from Barbary, in large casks or hogsheads. The common appearance of this gum is well known; and the various figures which it assumes seem to depend upon a variety of accidental circumstances attending its transudation and concretion. Gum arabic of a pale yellowish colour is most esteemed; on the contrary, those pieces which are large, rough, of a roundish figure, and of a brownish or reddish hue, are found to be less pure, and are said to be produced from a different species of mimosa; but the Arabian and Egyptian gum is commonly intermixed with pieces of this kind, similar to that which comes from the coast of Africa near the river Senegal.

Gum arabic does not admit of solution by spirit or oil; but in twice its quantity of water it dissolves into a mucilaginous fluid, of the consistence of a thick syrup; and in this state answers many useful pharmaceutical purposes, by rendering oily, resinous, and pinguious substances, miscible with water. The glutinous quality of gum arabic is preferred to most other gums and mucilaginous substances, as a demulcent in coughs, hoarsenesses, and other catarrhal affections, in order to obtund irritating acrimonious humours, and to supply the loss of abraded mucus. It has been very generally employed in cases of ardor urinæ and strangury; but it is the opinion of Dr. Cullen, "that even this mucilage, as an internal demulcent, can be of no service beyond the alimentary canal."

17. The senegal is a native of Guinea, and was some time ago introduced into Jamaica. The flowers are globular, yellow, and fragrant. The pods are brown, and of the size of a goose-quill. The tree, on being wounded, exudes gum arabic, though in less quantity, and less transparent, than that of the shops, which is obtained from the nilotica above described.

There are above 40 other species characterised in the Systema Vegetabilium.

MIMULUS, *monkey flower*, a genus of the didynamia angiospermia class of plants, with double stigmata, and a ringent monopetalous flower; the fruit is a bilocular capsule, with several seeds in each cell. There are three species.

MIMUSOPS, a genus of the octandria monogynia class of plants, the corolla of which consists of eight petals; and its fruit is a drupe. There are three species, trees of the East Indies.

MINA, in Grecian antiquity, a money of account, equal to a hundred drachms.

MINE, a deep pit under ground, whence various kinds of minerals are dug out; but the term is more particularly applied to those which yield metals. Where stones only are procured, the appellation of quarries is universally bestowed upon the places from which they are dug out, however deep they may be.

The internal parts of the earth, as far as they have been yet investigated, do not consist of one uniform substance, but of various strata or beds of substances, extremely different in their appearances, specific gravities, and chemical qualities, from one another. Neither are these strata similar to one another, either in their nature or appearance, in different countries; so that, even in the short extent of half a mile, the strata will be found quite different from what they are in another place. As little are they the same either in depth or solidity. Innumerable cracks and fissures, by the miners called lodes, are found in every one of them; but these are so entirely different in size and shape, it is impossible to form any inference from their size in one place to that in another. In these lodes or fissures the metallic ore is met with; and, considering the great uncertainty of the dimensions of the lodes, it is evident that the business of mining, which depends on that size, must in like manner be quite uncertain and precarious.

The insides of the fissures are commonly coated over with a hard, crystalline, earthy substance or rind, which very often, in the breaking of hard ore, comes off along with it; and is commonly called the capels or walls of the lode.

The breadth of a lode is easily known by the distance betwixt the two incrusted sides of the stones of ore; and if a lode yields any kind of ore, it is a better sign that the walls are regular and smooth, or at least that one of them is so, than otherwise; but there are not many of these fissures which have regular walls until they have been sunk down some fathoms.

Thus the inner part of the fissure in which the ore lies is all the way bounded by two walls of stone, which are generally parallel to one another, and include the breadth of the vein or lode. Whatever angle of inclination some fissures make in the solid strata at their beginning, they generally continue to do the same all along. Some are very uncertain in their breadth, as they may be small at their upper part and wide underneath; and vice versa. Their regular breadth, as well as their depth, is subject to great variation; for though a fissure may be many fathoms wide in one particular place, yet a little farther east or west it may not perhaps be one inch wide. This excessive variation happens generally in very compact strata, when the vein or fissure is squeezed, in a manner, through hard rocks which seem to compress and straiten it. A true vein or fissure, however, is never entirely obliterated, but always shews a string of metallic ore, or of a veiny substance; which often serves as a leader for the miners to follow, until it sometimes leads them to a large and richly impregnated part. Their length is, in a great measure, unlimited, though not the space best fitted for yielding metal. The richest state for copper is from 40 to 80 fathoms deep; for tin, from 20 to 60; and though a great quality of either may be raised at 80 or 100 fathoms, yet "the quantity is often too much decayed and dry for metal."

The fissures or veins of the Cornish mines extend from E. to W.; or, more properly, one end of the fissure points W. and by S., or W. and by N., while the other trends E. and by S. or E. and by N. Thus they frequently pass through a considerable tract of country with very few variations in their directions, unless they are interrupted by some intervening cause. But, besides this east and west direction, we are to consider what the miners call the underlying, or hade, of the vein or lode, viz. the deflection or deviation of the fissure from its perpendicular line, as it is followed in depth like the slope of the roof of a house, or the descent of the steep side of a hill. This slope is generally to the north or south; but varies much in different veins, or sometimes even in the same vein: for it will frequently slope or underlie a small space in different ways, as it may appear to be forced by hard strata on either side. Some of the fissures do not vary much from a perpendicular, while some deviate more than a fathom; that is, for every fathom they descend in perpendicular height, they deviate likewise as much to the south or north. Others differ so much from the perpendicular that they assume a position almost horizontal; whence they are also called horizontal or flat lodes, and sometimes lode-plots. Another kind of these has an irregular position with regard to the rest, widening horizontally for a little way, and then descending perpendicularly almost like stairs, with only a small string or leader to follow after; and thus they alternately vary, and yield ore in several flat or horizontal fissures. This, by the Cornish tinners, is called a floor or squat; which, properly speaking, is a hole or chasm impregnated with metal, making no continued line of direction or regular walls. Neither does a floor of ore descend to any considerable depth; for underneath it there appears no sign of a vein or fissure, either leading directly down, or any other way. This kind of vein is very rare in Britain. The fissures most common in Britain are the perpendicular and inclined, whether their direction is north or south, east or west.

The perpendicular and horizontal fissures probably remain little altered from their first position, when they were formed at the induration of the strata immediately after the waters left the land. The perpendicular fissures are found more commonly situated in level ground, at a distance from hills, and from the sea-shore; but with regard to the latter, we find that the upper and under masses of strata differ in their solidity and other properties. "Hence it is very plain that inclined fissures owe their deflection or underlie to some secondary cause, violence, or subsidence of the earth; for though perpendicular fissures are seldom to be seen, yet such as are inclined at very considerable depths become more and more perpendicular, as the more central strata, from the vast superincumbent weight, do not seem so likely to be driven out of their position as those which lie nearer the surface."

The fissures are often met with fractured as well as inclined; the reason of which has probably been a subsidence of the earth from some extraordinary cause. Though the metallic veins generally run from east to west, they are frequently intersected by veins or lodes of other matters, which run from north to south. Some of these cross veins contain lead or antimony, but never tin or copper. Sometimes one of these unmetallic veins intersects the true one at right angles; sometimes obliquely; and sometimes the mixture of both is so intimate, that the most expert miners are at a loss to discover the separated part of a true vein. When this last is intercepted at right angles, it is moved, either north or south, a very little way, perhaps not more than one fathom; in which case the miners having worked to a small distance in one of these directions, if they find themselves disappointed, turn to the other hand, and seldom fail of meeting with what they expected. Sometimes they are directed in their search by the pointing of a rib or string of the true vein; but when the interruption happens in an oblique direction, the difficulty of finding the vein again is much greater.

When two metallic veins in the neighbourhood of each other run in an oblique direction, and of consequence meet together, they commmonly produce a body of ore at the place where they intersect; and if both are rich, the quantity will be considerable; but if one is poor and the other rich, then both are either enriched or impoverished by the meeting. After some time they separate again, and each will continue its former direction near to the other; but sometimes, though rarely, they continue united.

It is a sign of a poor vein when it separates or diverges into strings; but, on the contrary, when several of them are found running into one, it is accounted a promising sign. Sometimes there are branches without the walls of the vein in the adjacent strata, which often come either obliquely or transversely into it. If these branches are impregnated with ore, or if they underlie faster than the true vein (that is, if they dip deeper into the ground), then they are said to overtake or come into the lode, and to enrich it; or if they do not, then they are said to go off from it, and to impoverish it. But neither these, nor any other, marks, either of the richness or poverty of a mine, are entirely to be depended upon: for many mines, which have a very bad appearance at first, do nevertheless turn out extremely well afterwards; while others, which in the beginning seemed very rich, turn gradually worse and worse: but, in general, where a vein has had a bad appearance at first, it will be imprudent to be at much expence with it.

Veins of metal, as has been already observed, are frequently so compressed betwixt hard strata that they are not an inch wide; nevertheless, if they have a string of good ore, it will generally be worth while to pursue them; and they frequently turn out well at last, after they have come into softer ground. In like manner, it is an encouragement to go on if the branches or leaders of ore enlarge either in width or depth as they are worked; but it is a bad sign if they continue horizontal without inclining downwards; though it is not proper always to discontinue the working of a vein which has an unfavourable aspect at first. Veins of tin are worth working when only three inches wide, provided the ore is good; and copper ores when six inches wide will pay very well for the working. Some of the great mines, however, have very large veins, with a number of other small ones very near each other. There are also veins crossing one another sometimes met with, which are called contras, vulgarly caunters. Sometimes two veins run down into the ground in such a manner that they meet in the direction of their depth; in which case the same observations apply to them as are applicable to those that meet in an horizontal direction. Sometimes a vein will suddenly disappear without giving any warning, by becoming narrower, or of worse quality; which by the miners is called a start or leap, and is very common in the mines of Cornwall. In one day's time they may thus be disappointed in the working a rich vein of tin, and have no further sign of any thing to work upon: at the fractured extremity of their vein they perceive a body of clay or other matter; and the method of recovering their vein is to drive on their work in the direction of the former part, so that their new work shall make the same angle with the clay that the other part of the vein does. Sometimes they sink a shaft down from the surface; but it is generally a matter of difficulty to recover a vein when thus lost.

The method of discovering mines is a matter of so much difficulty, that it seems surprising how those who were totally unacquainted with the nature of metals first came to think of digging them out of the earth. In modern times we know that mines have been frequently discovered by accident; as in sea-cliffs, among broken craggy rocks, by the washing of the tides or floods; also by irruptions and torrents of water issuing out of hills and mountains, and sometimes by the wearing of high roads.

Mines, however, are now most commonly discovered by investigating the nature of such veins, ores, and stones, as may seem most likely to turn to account: but there is a particular sagacity, or habit of judging from particular signs, which can be acquired only by long practice. Mines, especially those of copper, may also be discovered by the harsh and disagreeable taste of the waters which issue from them; though it is probable that this only happens when the ore lies above the level of the water which breaks out; for it does not seem likely that the taste of the ore could ascend, unless we were to suppose a pond or lake of water standing above it. The presence of copper in any water is easily discovered by immerging in it a bit of polished iron, which will thus instantly be turned of a copper colour, from the precipitation of the metal upon it. A candle, or a piece of tallow, put into water of this kind, will in a short time be tinged of a green colour.

After the mine is found, the next thing to be considered is, whether it may be dug to advantage. In order to determine this, we are duly to weigh the nature of the place, and its situation, as to wood, water, carriage, healthiness, and the like; and compare the result with the richness of the ore, the charge of digging, stamping, washing, and smelting.

The form and situation of the spot should be particularly well considered. A mine must either happen, 1. in a mountain; 2. in a hill; 3. in a valley; or, 4. in a flat. But mountains and hills are dug with much greater ease and convenience, chiefly because the drains and burrows, that is, the adits or avenues, may be here readily cut, both to drain the water, and to form gangways for bringing out the lead, &c. In all the four cases, we are to look out for the veins which the rains or other accidental circumstances may have laid bare; and if such a vein is found, it may often be proper to open the mine at that place, especially if the vein proves tolerably large and rich: otherwise the most commodious place for situation is to be chosen for the purpose, viz. neither on a flat, nor on the top of mountains, but on the sides. The best situation for a mine is a mountainous, woody, wholesome spot; of a safe easy ascent, and bordering on a navigable river. The places abounding with mines are generally healthy, as standing high, and every where exposed to the air; yet some places where mines are found prove poisonous, and can upon no account be dug.

Devonshire and Cornwall, where there are a great many mines of copper and tin, are a very mountainous country, which gives an opportunity in many places to make adits or subterraneous drains to some valley at a distance, by which to carry off the water from the mine, which otherwise would drown them out from getting the ore. These adits are sometimes carried a mile or two, and dug at a vast expence, as from 2000*l*. to 4000*l*. especially where the ground is rocky; and yet they find this cheaper than to draw up the water out of the mine quite to the top, when the water runs in plenty, and the mine is deep. Sometimes, indeed, they cannot find a level near enough to which an adit may be carried from the very bottom of the mine; yet they find it worth while to make an adit at half the height to which the water is to be raised, thereby saving half the expence.

The late Mr. Costar, considering that sometimes from small streams, and sometimes from little springs or collections of rainwater, one might have a good deal of water above ground, though not a sufficient quantity to turn an overshot-wheel thought, that if a sufficient fall might be had, this collection of water might be made useful in raising the water in a mine to the adit, where it might be carried off. But now the most general method of draining mines is by the steam-engine.

A Mine (in military affairs) is also a subterraneous cavity made according to the rules of art, in which a certain quantity of powder is lodged, which by its explosion blows up the earth above it.

It has been found by experiment that the figure produced by the explosion is a paraboloid; and that the centre of the powder, or charge, occupies the focus.

The place where the powder is lodged is called the chamber of the mine, or forneau.

The passage leading to the powder is called the gallery.

The line drawn from the centre of the chamber, perpendicular to the nearest surface of the ground, is called the line of least resistance.

The pit or hole, made by springing the mine, is called the excavation.

The fire is communicated to the mine by a pipe or hose, made of coarse cloth, whose diameter is about one inch and a half, called a saucisson (for the filling of which near half a pound of powder is allowed to every foot), extending from the chamber to the entrance of the gallery; to the end of which is fixed a match, that the miner who sets fire to it may have time to retire before it reaches the chamber.

To prevent the powder from contracting any dampness, the saucisson is laid in a small trough, called an auget, made of boards, three inches and a half broad, joined together lengthwise, with straw in it, and round the saucisson, with a wooden cover nailed upon it.

Galleries and chambers of mines.—Galleries made within the fortification, before the place is attacked, and from which several branches are carried to different places, are generally four feet or four and a half wide, and five feet or five and a half high. The earth is supported from falling in by arches and walls, if they are to remain for a considerable time; but when mines are made to be used in a short time, then the galleries are but three feet or three and a half wide, and five feet high, and the earth is supported by wooden frames or props.

The gallery being carried on to the place where the powder is to be lodged, the miners make the chamber. This is generally of a cubical form, large enough to hold the wooden box, which contains the powder necessary for the charge: the box is lined with straw and sand-bags, to prevent the powder from contracting dampness.

The chamber is sunk something lower than the gallery, if the soil permits; but where water is to be apprehended, it must be made higher than the gallery; otherwise the besieged will let in the water, and spoil the mine.

Quantities of powder to charge mines.—Before any calculation can be made of the proper charge for a mine, the density and tenacity of the soil in which it is to be made must be ascertained, either by experiment, or otherwise; for in soils of the same density, that which has the greatest tenacity will require the greatest force to separate its parts. The density is determined by weighing a cubic foot (or any certain quantity) of the soil; but the tenacity can only be determined by making a mine. The following table contains experiments in six different soils, which may be of some assistance to form a judgment of the nature of the soil, when an actual experiment cannot be had:

Nature of the Soil.	Density. Weight of 1 cubic foot.	Tenacity. Quantity of powder to raise 1 cub. fath.
1. Loose earth or sand	95 pds.	8 pds.
2. Common light soil	124	10
3. Loam, or strong soil	127	$12\frac{1}{4}$
4. Potter's clay, or stiff soil	135	$13\frac{1}{2}$
5. Clay, mixed with stones	160	16
6. Masonry - -	205	$21\frac{1}{2}$

Loading and stopping of mines.—The gallery and chamber being ready to be loaded, a strong box of wood is made of the size and figure of the chamber, being about one-third or one-fourth bigger than is required for containing the necessary quantity of powder: against the sides and bottom of the box is put some straw; and this straw is covered over with empty sand-bags, to prevent the powder from contracting any dampness: a hole is made in the side next the gallery, near the bottom, for the saucisson to pass through; which is fixed to the middle of the bottom, by means of a wooden peg, to prevent its loosening from the powder: or that, if the enemy should get to the entrance, he may not be able to tear it out. This done, the powder is brought in sand-bags, and thrown loose in the box, and covered also with straw and sand-bags; upon this is put the cover of the box, pressed down very tight with strong props; and, to render them more secure, planks are also put above them, against the earth, and wedged in as fast as possible.

This done, the vacant spaces between the props are filled up with stones and dung, and rammed in the strongest manner: the least neglect in this work will considerably alter the effect of the mine.

The auget is then laid from the chamber to the entrance of the gallery, with some straw at the bottom; and the saucisson laid in it, with straw over it: lastly, it must be shut with a wooden cover nailed upon it. Great care must be taken, in stopping up the gallery, not to press too hard upon the auget, for fear of spoiling the saucisson; which may hinder the powder from taking fire, and so prevent the mine from springing. The gallery is stopped up with stones, earth, and dung, well rammed, six or seven feet further from the chamber than the length of the line of least resistance.

MINERAL WATERS. See Waters.

MINERALOGY, is that science which treats of the solid and inanimate materials of which our globe consists; and these are usually arranged under four classes: the earthy, the saline, the inflammable, and the metallic, which are thus distinguished:

1. The earthy minerals compose the greater part of the crust of the earth, and generally form a covering to the rest. They are not remarkable for being heavy, brittle, or light-coloured. They are little disposed to chrystallize, are uninflammable in a low temperature, insipid, and without much smell.

2. The saline minerals are commonly moderately heavy, soft, sapid, and possess some degree of transparency.

3. The inflammable class of minerals is light, brittle, mostly opaque, of a yellow, brown, or black colour, seldom chrystallize, and never feel cold.

4. Metallic minerals are characterized by being heavy, generally opaque, tough, malleable, cold, not easily inflamed, and by exhibiting a great variety of colours, of a peculiar lustre.

Under each of these classes are various genera, species, sub-species, and kinds, which will be noticed in order. Sometimes, as in the vegetable kingdom, we find a strict affinity between different species of minerals, and in that case they are said to belong to the same family; but in mineralogy, one class does not always blend with another in a chemical point of view, or furnish that beautiful gradation and almost imperceptible union which is to be traced in the other kingdoms of nature.

As the external characters are of the first importance in facilitating our acquaintance with minerals, we shall briefly explain this subject, before we proceed to the classification of the different substances.

Of the external characters of Minerals.

The external characters of minerals are either generic or specific. The generic characters are certain properties of minerals, without any reference to their differences, as colour, lustre, weight, &c.; and the differences between these properties form the specific characters.

Generic characters may be general or particular. In the first division are comprehended those that occur in all minerals, in the last those that are found only in particular classes of minerals.

The particular generic external characters are thus advantageously arranged:

1. Colour.

2. Cohesion of particles; distinguished into solid, friable, and fluid.

In solid minerals are to be regarded the external shape, the external surface, and the external lustre. When broken, the lustre of the fracture, the fracture itself, and the shape of the fragments, are to be noticed. In distinct concretions, regard must be paid to the shape of the concretions, their surface, their lustre, transparency, streak, and soiling. All these may be ascertained by the eye. By the touch, we may discover the hardness of minerals their tenacity, frangibility, flexibity, their unctuosity, coldness, weight, and their adhesion to the tongue. By the ear we distinguish their sound, and by the smell and taste the qualities which these two senses indicate.

In friable minerals, external shape, lustre, aspect of particles, soiling, and degree of friability, are to be attended to.

In fluid minerals the lustre, transparency, and fluidity, are principal objects to be regarded.

The specific external characters of minerals are founded on the distinctions and varieties of the two great generic divisions. And first, of colours, the names of which are derived from certain bodies in which they most generally occur, either in a natural or artificial state, or from different mixtures and compositions of both.

I. Colour.

1. White. This may be snow-white, reddish-white, yellowish-white, silver-white, greyish-white, greenish-white, milk-white, or tin-white.

2. Grey. Lead-grey, blueish-grey, pearl-grey, reddish-grey, smoke-grey, greenish-grey, yellowish-grey, steel-grey, and ash-grey.

3. Black. Greyish-black, brownish-black, dark-black, iron-black, greenish-black, and blueish-black.

4. Blue. Indigo-blue, Prussian-blue, lavender-blue, smalt-blue, sky-blue.

5. Green. Verdigris-green, celaden-green, mountain-green, emerald-green, leek-green, apple-green, grass-green, pistachio-green, asparagus-green, olive-green, blackish-green, canary-green.

6. Yellow. Sulphur-yellow, lemon-yellow, gold-yellow, bell-metal-yellow, straw-yellow, wine-yellow, Isabella-yellow, ochre-yellow, orange-yellow, honey-yellow, wax-yellow, brass-yellow.

7. Red. Morning-red, hyacinth-red, brick-red, scarlet-red, copper-red, blood-red, carmine-red, cochineal-red, crimson-red, columbine-red, flesh-red, rose-red, peach-blossom-red, cherry-red, brownish-red.

8. Brown. Reddish-brown, clove-brown, hair-brown, yellowish-brown, tombac-brown, wood-brown, liver-brown, blackish-brown.

Besides these distinctions, colours may be clear, dark, light, or pale; they may have a tarnished appearance, a play, a changeability, an iridescence, an opalescence, a permanent alteration, and a delineation of figure or pattern, such as dotted, spotted, clouded, flamed, striped, veined, dendritic, or ruiniform.

II. Cohesion of Particles.

Minerals are divided into, 1. Solid, or such as have their parts coherent, and not easily moveable; 2. Friable, or that state of aggregation in which the particles may be overcome by simple pressure of the finger; and, 3. Fluid, or such as consist of particles which alter their place in regard to each other by their own weight.

1. *Solid Minerals.*

External aspect has three things to be regarded, 1. The shape; 2. The surface; and 3. The lustre. The external shape again may be common, particular, regular, or extraneous; and hence arise the specific differences.

1. The common external shape may be massive; disseminated coarsely, minutely, or finely; in angular pieces, sharp-cornered or blunt-cornered; in grains, large, coarse, small, fine, angular, flat, round; in plates, thick or thin; in membranes or flakes, thick, thin, or very thin.

The particular external shape may be longish, as dentiform, filiform, capillary, reticulatic, dendritic, coralliform, stalactitic, cylindrical, tubiform, claviform, or fruticose; roundish, as globular, spherical, ovoidal, spheroidal, amygdaloidal, botryoidal, reniform, tuberose, or fused-like; flat, as specular, or in leaves; cavernous, as cellular in various forms, with impressions, perforated, corroded, amorphous, or vesicular; entangled, as ramose, &c.

In the regular external shape or chrystallization are to be regarded its genuineness, according to which it may be either true or suppositious; its shape, made up of planes, edges, angles, in which are to be observed the fundamental figure and its parts, the kind of fundamental figure, the varieties of each kind of fundamental figure, with their accidents and distinctions, and the alterations which the fundamental figure undergoes by truncation, by bevelment, by acumination, or by a division of the planes. There are a variety of figures under each of these subdivisions.

It must be remarked also that the external shape may be extraneous, or derived from the animal and vegetable kingdoms, as in fossils and petrifications.

2. The external surface contains several varieties of distinctions. It may be uneven, granulated, rough, smooth, or streaked in various ways and directions.

3. The external lustre is the third generic external character, and is of much importance to be attended to. In this we have to consider the intensity of the lustre, whether it is splendent, shining, glistening, glimmering, or dull; next the sort of lustre, whether metallic or common. The latter is distinguished into semimetallic, adamantine, pearly, resinous, and vitreous.

Aspect of the Fracture of solid Minerals.

After the external aspect, the fracture forms no inconsiderable character in minerals. Its lustre may be determined as in the external lustre; but the fracture itself admits of great varieties. It may be compact, splintery, coarsely splintery, finely splintery, even, conchoidal, uneven, earthy, hackly. If the fracture is fibrous, we are to consider the thickness of the fibres, if coarse or delicate; the direction of the fibres, if straight or curved; and the position of the fibres, if parallel or diverging.

In the radiated fracture we are to regard the breadth of the rays, their direction, their position, their passage or cleavage. In the foliated fracture, the size of the folia, their degree of perfection, their direction, position, aspect of their surface, passage or cleavage, and the number of cleavages, are to be noted.

The shape of the fragments may also be very various-regular, as cubic, rhomboidal, trapezoidal, &c. or irregular, as cuneiform, splintery, tabular, indeterminately angular.

Aspect of the distinct Concretions.

The shape of the distinct concretions forms very prominent external characters. They may be granular, different in shape, or in magnitude; they may be lamellar, distinct, concretious, differing in the direction of the lamellæ, in the thickness, with regard to shape, and in the position.

The surface of the distinct concretions may be smooth, rough, streaked, or uneven; as for their lustre, it may be determined in the same manner as the external lustre.

General Aspect as to Transparency.

Minerals, as is well known, have different degrees of transparency, which may be considered among their external characters. They may be transparent, semitransparent, translucent, translucent at the edges, or opaque.

The Streak.

The colour of this external character may be either similar or different. It is presented to us when a mineral is scraped with the point of a knife: and is similar, when the powder that is formed is of the same colour with the mineral, as in chalk; or dissimilar or different, as in cinnabar, orpiment, &c.

The Soiling or Colouring

Is ascertained by taking any mineral substance between the fingers, or drawing it across some other body. It may soil strongly, as in chalk, slightly, as in molybdena, or not at all, which is a quality belonging to most of the solid minerals. All the preceding external characters are recognized by the eye.

External Characters from the Touch.

These are eight in number, and are not destitute of utility to the mineralogical student. 1. Hardness; 2. Tenacity; 3. Frangibility; 4. Flexibility; 5. Adhesion to the tongue; 6. Unctuosity; 7. Coldness; 8. Weight.

Hardness may be tried by a capacity to resist the file, yielding a little to it, by being semi-hard, soft, or very soft. Tenacity has different degrees, in substances being brittle, sectile or mild, or ductile. The frangibility consists in minerals being very difficultly frangible, difficultly frangible, easily frangible, or very easily frangible. The flexibility is proved by being simply flexible, elasticly flexible, commonly flexible, or inflexible. The adhesion to the tongue may be strongly adhesive, pretty strongly, weakly, very weakly, or not at all. Unctuosity may be meagre, rather greasy, greasy, or very greasy. Coldness is subdivided into cold, pretty cold, rather cold. Weight may be distinguished into swimming or supernatant, light, rather light, heavy, very heavy. The three last divisions from the touch, are in the Wernerian system regarded as anomalous; but they seem properly to be classed under this head.

External Characters from the Sound or Hearing.

The different kinds of sound which occur in the mineral kingdom are, 1. A ringing sound, as in native arsenic and thin splinters of horn-stone; 2. A grating sound, as in fresh-burnt clay; 3. A creaking sound, as that of natural amalgam.

2. Friable Minerals.

The external characters drawn from minerals of this class are derived, first, from the external shape, which may be massive, disseminated, thinly coating, spumous, or dendritic: secondly, from the lustre, regarded under its intensity, whether glimmering or dull, and its sort, whether common glimmering or metallic glimmering: thirdly, from the aspect of the particles, as being dusty or scaly: fourthly, from soiling or colouring, as strongly or lightly: and lastly, from the friability, which may be loose or cohering.

3. Fluid Minerals.

Of external characters drawn from fluid minerals, there are only two kinds, which include three varieties: 1. The lustre, which is either metallic, as in mercury, or resinous, as in rock oil. 2. The transparency, which is transparent, as in naphtha; turbid, as in mineral oil; or opaque, as in mercury. 3. The fluidity, which may be fluid, as in mercury, or viscid, as in mountain tar.

External Characters from the Smell.

These may be spontaneously emitted and described, as bituminous, faintly sulphureous, or faintly bitter; or they may be produced by breathing on, and yield a clay-like smell; or they may be excited by friction, and smell urinous, sulphureous, garlick-like, or empyreumatic.

External Character from the Taste.

This character prevails chiefly in the saline class, and it contains the following varieties: a sweetish taste, sweetish astringent, styptic, saltly bitter, saltly cooling, alkaline, or urinous.

Having now given a synoptical view of the external characters of minerals, we shall proceed to their classification, and in this we shall chiefly follow the names and arrangement of professor Jameson.

CLASS I.

EARTHY FOSSILS.

First Genus. DIAMOND.

Diamond.

This precious stone has great variety of shades, exhibiting a beautiful play of colours. It occurs in indeterminately angular and completely spherical grains, which present planes of chrystallization, or are actually chrystallized. Its fundamental chrystal is the octaedron, which passes into various forms. It is hard in the highest degree, brittle, not very difficultly frangible, and has a specific gravity of 3.600.

The diamond has, by modern experiments, been proved to be nearly pure carbon, and begins to burn at 14° or 15° of Wedgewood. See Plate I. Mineralogy, figs. 1. and 2.

Second Genus. ZIRCON.

First Species. Zircon.

The prevailing colour is grey, but it occurs likewise green, blue, red, yellow, and brown, with various intermediate tints.

It is found most commonly in roundish angular pieces, with rounded angles and edges. When chrystallized, the figure is generally a rectangular four-sided prism, somewhat flatly acuminated by four planes, set on lateral planes; but of this figure there are several varieties. The chrystals are almost always very small, have a smooth surface, bordering on strongly splendent. Internally, the lustre is strongly splendent, passing into adamantine. Fig. 3.

Zircon is hard in a very high degree, brittle, frangible without great difficulty. Specific gravity 4.700. It forms a colourless transparent mass with borax, but is infusible by the blowpipe without addition.

Found in the island of Ceylon, where it was first discovered, and lately in Norway, imbedded in a rock composed of hornblende and felspar.

Frequently cut as a precious stone, and used as an inferior kind of diamond, of which it was once considered as a variety. Its play of colours very considerable.

Second Species. Hyacinth.

The chief colour is red, passing to reddish-brown, and to orange-yellow. The figure a rectangular four-sided prism, flatly acuminated by four planes, which are set in the lateral edges. Of this figure, however, several varieties occur.

The chrystals are generally small, and always imbedded. The lateral planes smooth, and externally shining. Internally it is splendent and glassy, inclining somewhat to resinous. Fig. 4.

The hyacinth is transparent, very hard, frangible without particular difficulty; feels a little greasy when cut, and has a specific gravity of about 4.000.

Is fusible with borax. Exposed to the blowpipe it loses its colour, but not its transparency.

Occurs in rocks of the newest floetz trap formation, and sometimes in sand. Is a native of Ceylon, the country of gems; of Spain, of Portugal, France, Italy, Saxony, and probably Scotland.

It takes a fine polish, and when the colours are good, it is highly valued. A third species, called cinnamon stone, has lately been discovered at Columbo, in Ceylon.

Third Genus. FLINT.

First Species. Chrysoberyl.

The prevailing or general colour is asparagus-green, passing into a variety of allied shades. It exhibits a milk-white light; occurs in roundish and angular grains, which sometimes approach in shape to the cube. It is seldom chrystallized; but when in this state, it commonly presents a longish six-sided table, having truncated lateral edges, and longitudinally streaked lateral planes. The chrystals are small, externally shining, and internally splendent. Fig. 5.

It is hard, brittle, not very easily frangible, with a specific gravity of 3.600. Without addition, it is infusible.

The chrysoberyl is found in Brazil, and in the sand of Ceylon. It is sometimes set in rings with a yellow foil, but is rarely in the possession of our jewellers.

Second Species. Chrysolite.

The chief colour is pistachio-green, of all degrees of intensity. It occurs in original angular sharp-edged pieces, with a rough, scaly, splintery surface, and when chrystallized, exhibits a broad rectangular four-sided prism, with its lateral edges sometimes truncated, sometimes bevilled, and acuminated by six planes. Fig. 6.

The external surface of the chrystals is splendent, internally splendent, and vitreous.

Third Species. Olivine.

The colour is generally asparagus-green, of various degrees of intensity. It is found imbedded also in roundish pieces and grains; and when chrystallized, which is rare, in rectangular four-sided prisms.

Internally, it is shining, varying between glistening and splendent. It is semitransparent, very easy frangible; in a low degree hard, and not particularly heavy. It is nearly infusible without addition. Occurs imbedded in basalt; is frequently found in Bohemia, and also in Hungary, Austria, France, England, Ireland, Scotland, Sweden, Iceland, and Norway. Pieces as large as a man's head have been found in some parts of Germany.

Fourth Species. Augite.

The general colour is blackish-green. It occurs chiefly in indeterminate angular pieces and roundish grains. Occasionally it is chrystallized, and presents broad rectangular six-sided prisms. The chrystals are mostly small. Internally the lustre is shining, approaching sometimes to splendent.

The augite is only translucent, and but faintly transparent. It is hard, not very easily frangible, and not particularly heavy.

It is found in basalt, either singly or accompanied with olivine, in Bohemia, Hungary; at Arthur's-seat, near Edinburgh; in some of the Hebrides, and in Norway. From olivine it is distinguished by its darker colours, the form of its chrystallization, and its greater hardness.

Fifth Species. Vesuviane.

Its principal colour is dark olive-green, passing into other allied shades. It occurs massive, and often chrystallized in rectangular four-sided prisms. The chrystals are mostly short, and placed on one another. Externally their surface alternates between glistening and splendent. Internally they are glistening, with a lustre between vitreous and resinous.

The vesuviane is translucent, hard in a moderate degree, and approaching to heavy. Before the blowpipe it melts without addition.

It is found among the exuviæ of Vesuvius, from whence it derives its name, in Siberia and Kamtschatka. At Naples, it is cut into ring-stones, and sold under various names.

Sixth Species. Leuzite.

The colours are yellowish and greyish-white. It occurs mostly in original round and angular grains. When chrystallized, it exhibits acute double eight-sided pyramids. Internally it is shining, and approaching to glistening, with a vitreous lustre, inclining somewhat to resinous.

The leuzite is translucent and semitransparent. It is hard in a low degree, brittle, easily frangible, and not very heavy. It is infusible without addition. With borax, it forms a brownish transparent glass.

It is found in rocks of the newest floetz trap formation, particularly in basalt, near Naples, and in the vicinity of Rome. Bergman gave it the name of white garnet; but Werner has ascertained it to be a distinct species of itself.

Seventh Species. Melanite.

The general colour is velvet-black. It occurs chrystallized in a six-sided prism. The chrystals are middle-sized or small. Externally they are smooth and shining, approaching to splendent; internally shining, inclining to glistening.

The melanite is opaque, hard, pretty easily frangible, and not very heavy. It occurs imbedded in rocks of the newest floetz trap formation, and hitherto has been found only at Frescati and St. Albano, near Rome.

Eighth Species. Garnet.

This is divided into two sub-species, the precious garnet and the common garnet. See Garnet, and fig. 7.

Ninth Species. Pyrope.

The colour is dark blood-red. It occurs in small and middle-sized roundish and angular grains; but never chrystallized. Its lustre is splendent and vitreous. It is completely transparent, hard so as to scratch quartz, and not particularly heavy.

The pyrope is found imbedded in serpentine in Saxony and Bohemia. In Fifeshire, Scotland, it is found in the sand on the sea shore. It is employed in various kinds of jewellery, and is generally set in a good foil.

Tenth Species. Grenatite.

The colour is a dark reddish-brown. It is always chrystallized in broad six-sided prisms. The chrystals are small and middle-sized, internally glistening, with a lustre between vitreous and resinous.

The grenatite varies from opaque to translucent, is hard, brittle, easily frangible, and not particularly heavy.

It is found imbedded in mica slate, in St. Gothard, Switzerland; and is also met with in Britanny and in Spain.

Eleventh Species. Spinelle.

The predominant colour is red, which passes on into blue, green, yellow, and brown. It occurs in grains, and likewise chrystallized in octaedrons with several variations. The chrystals are very rarely middle-sized. Externally and internally the lustre is splendent and vitreous.

The spinelle alternates from transparent to vitreous: it is hard in a pretty high degree, and approaches to heavy. It is fusible with borax: occurs in rocks belonging to the newest floetz trap formation; and is found in Pegu and Ceylon. It is used as a precious stone, and considerably valued, though possessing neither the hardness nor the fire of the oriental ruby.

Twelfth Species. Sapphire.

The principal colour Berlin blue; but it is found also red, with all the intermediate shades between these two colours. It occurs in small rolled pieces, and chrystallized in double three-side pyramids, of which there are several varieties in figure.

The chrystals are small and middle-sized. Internally the lustre is splendent and vitreous. It is more or less transparent in different specimens. Some varieties, when cut, exhibit a star of six rays. Fig. 8.

The sapphire is hard in the highest degree, but yields to the diamond; it is easily frangible, and rather heavy, having a specific gravity of about 4.000.

It is infusible without addition: occurs in rocks of the newest floetz trap formation, and is supposed to be an inmate of granite, syenite, and other primitive rocks.

This precious stone is found in the utmost beauty in Pegu and Ceylon. It is also a native of Portugal, of France, and of Bohemia. Next to the diamond, it is the most valuable of gems, and is used in the finest kind of jewellery.

It should be observed, that the violet-coloured sapphire is the oriental amethyst; that the yellow is the oriental chrysolite and topaz; and that the green is the oriental emerald.

Thirteenth Species. Corundum.

The principal colour is a greenish-white, of various degrees of intensity. It occurs massive, disseminated, in rolled pieces, and chrystallized. The chrystallizations resemble those of the sapphire, and the chrystals are middle-sized and imbedded.

The corundum is duplicating translucent, hard in a high degree, pretty easily frangible, and approaches to heavy. It is supposed to occur imbedded in granite, syenite, or green-stone, and is found in the Carnatic and on the coast of Malabar. See Corundum.

Fourteenth Species. Diamond Spar.

The colour is a dark hair-brown. It occurs massive, disseminated, in rolled pieces, and chrystallized in six-sided prisms, or very acute six-sided pyramids. Internally, its lustre is splendent, approaching in a slight degree to adamantine. It may be cut so as to present an opalescent star of six rays, of a peculiar pearly light.

It is translucent on the edges, hard in a high degree, easily frangible, and not particularly heavy.

The diamond spar probably occurs in granite. It has hitherto been found only in China. Both this stone and corundum are employed in cutting and polishing hard minerals, and they seem to be nearly allied to each other.

Fifteenth Species. Emery.

Emery is hard in the highest degree, not very easily frangible, and is heavy. It occurs in beds of talc and steatite, and is frequently accompanied with calcspar and blende. It is found in Saxony, in the islands of the Archipelago, in Spain, Normandy, and is said also to be a native of the isles of Guernsey and Jersey.

It is of great use in cutting and polishing hard bodies.

Sixteenth Species. Topaz.

The chief colour is a wine-yellow, of all degrees of intensity. It is found massive, disseminated, and sometimes rolled, but most commonly chrystallized in oblique eight-sided or four-sided prisms, which exhibit several varieties. The chrystals are small and middle-sized, externally splendent; internally splendent, and shining: lustre vitreous.

The topaz alternates from translucent to transparent, and is duplicating transparent. It is hard in a high degree, easily frangible, and is not particularly heavy. It is fusible with borax; and some kinds in a gentle heat turn white, and are sometimes sold for diamonds.

It is commonly found in veins that traverse primitive rocks in Brazil, Siberia, in Pegu, and Ceylon; in Bohemia, Saxony, and in Cornwall. Exhibiting various forms and tints, it has often been confounded with other precious stones. It is much used in seals and rings.

Seventeenth Species. Emerald.

The green called emerald is the characteristic colour of this species, but it has all degrees of intensity from deep to pale. It is said to occur massive and in rolled pieces, but most commonly chrystallized in low equiangular six-sided prisms. The chrystals are middle-sized and small. Internally the lustre is intermediate between shining and splendent, and is vitreous. It alternates from transparent to translucent, and is duplicating transparent.

The emerald is hard, not particularly heavy, melts easily with borax, but is scarcely fusible before the blowpipe. It occurs in veins that traverse clay-slate, and at present is only found in South America, particularly in Peru, though the Romans are said to have procured it from Egypt and Ethiopia.

From the beauty and vivacity of its colour, the charming emblem of the vegetable kingdom, this precious stone is much admired, and employed in the most expensive kinds of jewellery. See Emerald.

Eighteenth Species. Beryl.

This is divided into two sub-species, the precious and the schorlous beryl. See Beryl, and fig. 9.

Nineteenth Species. Schorl.

This is divided into two sub-species, common schorl and tourmaline. Fig. 10.

Twentieth Species. Thumerstone.

The colour is commonly clove-brown, of various degrees of intensity. It is occasionally found massive, more frequently disseminated; but generally chrystallized in very flat and oblique rhombs. Externally, its lustre is generally splendent; internally, it alternates from glistening to shining, and is vitreous.

This species alternates from perfectly transparent to weakly translucent. It is pretty hard, very easily frangible, and not particularly heavy. It appears to be peculiar to the primitive mountains, and is found imbedded in limestone in Saxony, Dauphiny, Norway, Siberia, and Cornwall. Fig. 11.

Twenty-first Species. Iron-Flint.

The colour a yellowish-brown, bordering on liver-brown. It occurs commonly massive, but also chrystallized in small equiangular six-sided prisms. Externally, its lustre is splendent; internally, shining, and is intermediate between vitreous and resinous.

Iron-flint is opaque, and slightly translucent on the edges. It is pretty hard, somewhat difficultly frangible, and approaching to heavy. It occurs in iron-stone veins, and is found in Saxony, and, according to Karsten, at Bristol. It renders the iron ore, along with which it is dug, very difficult of fusion.

Twenty-second Species. Quartz.

Werner divides this into five sub-species, amethyst, rock chrystal (fig. 12), milk-quartz, common quartz, and prase. The first sub-species is again subdivided into common amethyst and thick fibrous amethyst. See QUARTZ, AMETHYST, &c.

Twenty-third Species. Horn-Stone.

Horn-stone is divided into three sub-species, splintery horn-stone, conchoidal horn-stone, and wood-stone.

First Sub-species. Splintery Horn-Stone.

The common colour grey, but often red, with various shades of each. It is usually found massive, or in large balls. Internally its lustre is dull; but glimmering when it approaches to the nature of quartz. It is more or less translucent on the edges, hard, brittle, very difficultly frangible, and not particularly heavy.

The substance is infusible without addition; and is found in the shape of balls in limestone, and sometimes forming the basis of porphyry. It is a native of Bavaria, Sweden, and the Shetland islands; and appears to differ from quartz in containing a larger proportion of alumina.

Second Sub-species. Conchoidal Horn-Stone.

The colour runs from greyish-white to yellowish and greenish-white. It occurs massive. Internally, it is a little glistening, strongly translucent on the edges, hard, easily frangible, and not particularly heavy.

Conchoidal horn-stone is found in beds or in veins, accompanied with agate, at Goldberg, in Saxony.

Third Sub-species. Wood-Stone.

The prevailing colour is ash-grey, but with many different shades. Its shape is exactly conformable to its former woody form, whether trunk, branches, or roots. Internally, it is sometimes dull, and sometimes glimmering and glistening; slightly translucent on the edges, pretty hard, easily frangible, and not particularly heavy.

It is found insulated in sandy loam in Saxony, Bohemia, Russia, Hungary, and at Loch Neagh in Ireland. It receives a good polish, and is applied to the same purposes as agate.

Twenty-fourth Species. Flint.

The general colour is grey, but with many varieties. It occurs massive, in regular plates, in angular grains and species, in globular and elliptical rolled pieces, in the form of sand, and tuberose and perforated. Sometimes it is chrystallized, when it exhibits double six-sided prisms, or flat double three-sided pyramids. Internally, the lustre is glimmering, translucent on the edges, hard, easily frangible, and not particularly heavy.

Twenty-fifth Species. Chalcedony.

This is divided into two sub-species, chalcedony and carnelian.

First Sub-species. Common Chalcedony.

The most common colour is grey. The external shape is various, being massive, in blunt-edged grains and rolled pieces, in original round balls, &c. &c. Internally, the chalcedony is almost always dull, commonly semitransparent, hard, brittle, rather difficultly frangible, and not particularly heavy. It occurs in amygdaloid, and in porphyry; and is found in Transylvania, in Iceland, Siberia, Cornwall, Scotland, and the Hebrides. Being susceptible of a fine polish, it is employed as an article of jewellery.

Second Sub-species. Carnelian.

The principal colour is a blood-red, of all degrees of intensity. It commonly occurs in roundish pieces, and also in layers: the lustre is glistening, bordering on glimmering, and is semitransparent. See CARNELIAN.

Agate.

The fossils known under this name are all compound substances; and hence cannot have a particular place in any systematic arrangement. Werner therefore has placed them as a supplement to the species chalcedony, which forms a principal constituent part of them, and disposes them according to their colour-delineations, thus: 1. Fortification agate; 2. Landscape agate; 3. Ribbon agate; 4. Moss agate; 5. Tube agate; 6. Clouded agate; 7. Land agate; 8. Star agate; 9. Fragment agate; 10. Punctated agate; 11. Petrifaction agate; 12. Coal agate; 13. Jasper agate. They are all compounded of chalcedony, carnelian, jasper, horn-stone, quartz, heliotrope, amethyst, indurated lithomarge, and opal, in different quantities and proportions; and are found in great abundance in Germany, France, England, Scotland, Ireland, and the East Indies.

The uses of agate are various. It is cut into vases, mortars, snuff-boxes, seals, handles to knives, and for many other useful purposes. See AGATE.

Twenty-sixth Species. Heliotrope.

The principal colour is intermediate between leek and dark celadon green, or mountain green. It occurs massive, and in angular as well as rolled pieces. Internally the lustre is glistening, and is always resinous. It is commonly translucent in the edges; is easily frangible, hard, and not particularly heavy.

Heliotrope is found in rocks belonging to the floetz trap formation, in Asia, Persia, Siberia, Saxony, and Iceland.

On account of its beautiful colour and its hardness, it is employed for nearly the same purposes as agate. See HELIOTROPE.

Twenty-seventh Species. Plasma.

The usual colour is intermediate between grass and leek-green, and of different degrees of intensity. It occurs in indeterminably angular pieces, which have a rough earthy crust. Internally its lustre is glistening. It is intermediate between semitransparent and strongly translucent, hard, brittle, frangible without great difficulty, and not particularly heavy.

Hitherto it has only been found among the ruins of Rome, and constituted a part of the ornamental dress of the antient Romans.

Twenty-eighth Species. Chrysopras.

Its characteristic colour is apple-green, of all degrees of intensity. It is found massive in angular pieces, and in thick plates. Internally it is dull; the lustre intermediate between translucent and semitransparent. It is hard, not very difficultly frangible, nor particularly heavy; and is found along with quartz, opal, chalcedony, &c. at Kosemuctz, in Lower Silesia.

Chrysopras is principally used for ring-stones, and some varieties are highly esteemed; but it is difficult to cut and polish.

Twenty-ninth Species. Flinty Slate.

This has been divided into two sub-species, common flinty slate, and Lydian stone.

First Sub-species. Common Flinty Slate.

The principal colour is grey, but there are many varieties of shades. It occurs massive in whole beds, and frequently in blunt-angled pieces, with a smooth and glimmering surface. Internally, it is faintly glimmering; more or less translucent on the edges; hard, brittle, difficultly frangible, and not particularly heavy.

It occurs in beds in transitive mountains in Saxony, at the lead-hills in Scotland, and other places.

Second Sub-species. Lydian Stone.

The colour is greyish-black, passing into velvet-black. It occurs massive, and is frequently found in trapezoidal-shaped rolled pieces. Internally, it is glimmering; opaque, hard, pretty easily frangible, and not particularly heavy. It is found in similar formations with the preceding, near Prague and Carlsbad in Bohemia, in Saxony, and in the Moorfoot and Pentland hills, near Edinburgh.

When polished, it is used as a test-stone for determining the purity of gold and silver; but is less suited for this purpose than basalt, and some kind of clay slate.

Thirtieth Species. Cat's Eye.

The principal colour is grey, of which it presents many varieties. It occurs in blunt-edged pieces, in rolled pieces, and likewise massive. Internally, it is shining; usually translucent, and sometimes also semitransparent. It is hard, easily frangible, and not particularly heavy.

Its geognostic situation is unknown. It is imported from Ceylon and the coast of Malabar; and is usually cut for ring-stones. Some of the varieties are highly valued.

Thirty-first Species. Prehnite.

The colours are various shades of green, white, and yellow. It is sometimes massive, and sometimes chrystallized in oblique four-sided tables. Externally, the chrystals are smooth and shining; internally, inclining to glistening and pearly.

Prehnite is translucent, sometimes passing into semitransparent and transparent: it is hard, easily frangible, and not very heavy. It occurs in Dauphiny in veins of the oldest formation; in Scotland in rocks belonging to the newest floetz trap formation; and was first discovered in Africa by colonel Prehn, from whom it receives its appellation.

Thirty-second Species. Zeolite.

This species is divided by Werner into five sub-species, 1. Mealy zeolite; 2 Fibrous zeolite; 3. Radiated zeolite; 4. Foliated zeolite; 5. Cubec zeolite. As they are principally distinguished from each other by fracture, hardness, and lustre, we shall only observe, that the chief colours of all are yellowish, whitish, and reddish, with a variety of intermediate shades; that zeolite occurs massive, in angular pieces, in balls, and sometimes chrystallized in short and oblique four-sided prisms, and in perfect smooth planed cubes; that it is according to the sub-species opaque, translucent, or even transparent; and that it is semihard, easily frangible, and not particularly heavy.

Zeolite occurs in rocks belonging to the newest formation, but is sometimes, though rarely, found in primitive green stone, either disseminated, in cotemporaneous balls, or lining or filling up air cavities or veins. All the different sub-species are natives of Scotland. The mealy zeolite is found in the Isle of Sky; the fibrous and radiated in the isles of Canary and Sky; the foliated in Staffa, and the cubic in the same isle, and likewise in Sky. They are likewise met with in Iceland, in Sweden, in Germany, and the East Indies. Figs. 13 and 14.

Thirty-third Species. Cross-Stone.

The colour is a greyish-white. It occurs chrystallized, either in broad rectangular four-sided prisms, or in twin chrystals. The chrystals are mostly small, and aggregated on one another. Both the internal and the external lustre is shining, inclining to splendent or glistening.

The cross-stone is translucent passing to transparent, semi-hard, easily frangible, and not particularly heavy. It has hitherto been found only in mineral veins, and in agate-balls, at Strontian, in Argyleshire, and at Andreasberg, in Hartz, as well as some other places.

Thirty-fourth Species. Agate-Stone.

The colour is a perfect azure blue, of different shades. It is found massive, disseminated, and in rolled pieces. The lustre is glistening and glimmering. It is translucent on the edges, pretty hard, brittle, easily frangible, and not particularly heavy.

The geognostic situation is not correctly ascertained. It is said to have been found near the lake of Baikal, in Siberia, in a vein accompanied with garnet, felspar, and pyrites. It occurs in Persia, China, Tartary, and Siberia; in South America; but in Europe has only been found among the ruins of Rome.

Its beautiful colour renders it an object of attraction, and being capable of receiving a high polish, it is applied to various useful purposes, and enters into the composition of many diffe ent ornaments. It is the lapis lazuli of painters. Werner is constantly making additions to his species under every genus.

Of those belonging to the flint genus, which are less known, and have been described with less precision than the preceding, are coccolite, found in Sweden and Norway; pistazite, found in Norway, Bavaria, and France; ceylanite, in Ceylon; enclase, in Peru; hyalite, near Franckfort; menilite, near Paris; lomonite, in Lower Britanny; natrolite, in Suabia; azurite, in Stiria, &c.; andalusite, or hardspar, in Saxony, France, and Spain; chiastolite, or hollow spar, in France and Spain, and probably in Cumberland; scapolite, in Norway; and arctizite, or wernerite, in Sweden, Norway, Switzerland, and lazulite.

FOURTH GENUS.

Clay *Genus.*

First Species. Jasper.

This is dividedinto six sub-species; Egyptian jasper, striped jasper, porcelain jasper, common jasper, agate jasper, and opal jasper.

Second Species. Opal.

Werner divides this into four sub-species, precious opal, common opal, semi-opal, and wood opal.

Third Species. Pitch-Stone.

The colours are black, green, brown, red, and occasionally grey. It occurs always massive in great beds and rocks. Internally, its lustre is shining. It is commonly translucent in a small degree, brittle, and pretty easily frangible.

Pitch-stone is fusible without addition; occurs in beds in the newest porphyry and floetz trap formation; and is found in Saxony, Hungary, in several of the Hebrides, and in Dumfriesshire. Some of its varieties bear a striking resemblance to pitch, from whence it receives its appellation.

Fourth Species. Obsidian.

The principal colour is velvet-black. It always occurs in angularly roundish-pieces. Internally it is splendent. Some of the varieties are translucent, others semi-transparent. It is hard, easily frangible, and not very heavy.

Obsidian occurs insular in the newer porphyry formation, and is found in Hungary, Iceland, in Peru, and various other countries. When cut and polished, it is sometimes used for ornamental purposes, and mirrors for telescopes have been formed of it. It probably owes its origin to fire.

Fifth Species. Pearl Stone.

Its colour is generally grey, sometimes black and red. It occurs vesicular, and the vesicles are long and roundish, with a shining pearly lustre. It is translucent on the edges, not very brittle, very easily frangible, and rather light.

Pearl stone is found in beds of porphyry, near Tokay, in Hungary, in the north of Ireland, and the Hebrides.

Sixth Species. Pumice Stone.

Its usual colour is a light yellowish-grey, passing into different neighbouring shades. It is small, and lengthened vesicular: its internal lustre glistening, generally translucent in the edges, soft, and seldom semi-hard, very brittle, easily frangible, and swims in fluids.

It occurs in various situations, generally accompanied by rocks that belong to the floetz trap formation; and though usually classed among volcanic productions, in some situations it evidently is of aquatic origin. It is found in the Lipari islands, in Hungary, Iceland, and on the banks of the Rhine; and is used for polishing stones, metals, glass, and ivory; and also for preparing parchment.

Seventh Species. Felspar

Is divided into four sub-species; compact felspar, common felspar, adularia, and Labradore stone. Fig. 15.

Eighth species. Pure Clay

Is snow white, with occasionally a yellowish tinge, and occurs in kidney-shaped pieces, which have no lustre. It is opaque, soils very little, adheres slightly to the tongue, is light, and intermediate between soft and friable.

Pure clay is found immediately under the soil, accompanied with foliated gypsum and selenite, at Halle, in Saxony, only.

Ninth species. Porcelain Earth.

The colour is generally a reddish-white, of various degrees of intensity. It occurs massive and disseminated; its particles are fine and dusty, slightly cohering, and feeling fine and light.

It is found in beds in gneiss, accompanied with quartz and other substances, in Saxony, at Passau, Limoges, and in Cornwall. In China and Japan, where it is called kaolin, it is very abundant. It forms the basis of china ware.

Tenth species. Common Clay.

This is divided into six sub-species, as follow:

1. Loam, of a yellowish-grey colour, frequently spotted with yellow and brown, and occurring massive. It is dull and weakly glimmering, colours a little, adheres pretty strongly to the tongue, and feels slighty greasy. It is often mixed with sand, gravel, and iron ochre.

2. Potter's clay is of two kinds, earthy and slaty. The earthy is of a yellowish and greyish-white colour in general; occurs massive; is opaque, colours a little, feels somewhat greasy, and adheres strongly to the tongue. Slaty potter's clay is generally of a dark ash-grey colour, and feels more greasy than the preceding. It occurs in great rock masses, and in alluvial land. Both kinds are universally distributed, and are of great importance in the arts and in domestic economy.

3. Pipe clay is greyish-white, passing into yellowish-white, occuring massive, of a glimmering lustre, and having its particles pretty coherent. It feels rather greasy, is easily frangible, and adheres pretty strongly to the tongue.

4. Variegated clay is commonly white, red, and yellow, striped, veined, and spotted. It occurs massive, is soft, passing into triable, feels a little greasy, and adheres somewhat to the tongue. It is found in Upper Lusatia.

5. Clay-stone is commonly grey or red, with various intermediate tints. It occurs massive, is dull, opaque, soft, pretty easily frangible, feels rather meagre, and does not adhere to the tongue. It forms vast rock masses, occurs in beds and veins, and is found in Saxony, in Scotland, and in Shetland.

6. Slate clay is of a grey colour, presenting several varieties. It is massive, internally

dull, opaque, pretty soft, mild, easily frangible, adheres a little to the tongue, and feels meagre. It is generally found wherever the oval, floetz trap, and alluvial formations occur.

Eleventh species. Polier, or Polishing-Stone,

Is of a yellowish-grey colour, striped, and the colours alternate in layers. It occurs massive, is dull, very soft, adheres to the tongue, feels fine but meagre, and is nearly swimming. It is found in the vicinity of pseudo-volcanoes, though hitherto it has only been discovered in Bohemia.

Twelfth species. Tripoli

Is of a yellowish-grey colour, passing into ash-grey; occurs massive, is internally dull, very soft, feels meagre and rough, does not adhere to the tongue, and is rather light. It is found in veins and beds in floetz rocks in Saxony, in Derbyshire, and many other countries besides Tripoli, from whence it was first brought. Its use in polishing metals and minerals is well known.

Thirteenth species. Alum-Stone

Is of a greyish-white colour, occurs massive, shews a tendency to chrystallization, is soft, passing to friable, and light. It is found at Tolfa, near Rome, from whence the famous Roman alum is manufactured.

Fourteenth species. Alum Earth.

The colour is a blackish-brown, and brownish-black; it is massive, dull, feels a little meagre, and somewhat greasy; is intermediate between soft and friable, and light. It is found in beds of great magnitude in alluvial land, and in floetz trap formation in several parts of Germany, in Naples, and in France. It is lixiviated to obtain the alum it contains.

Fifteenth species. Alum-Slate

Is divided into two sub-species, as follow:

1. Common alum-slate is between a greyish and bluish-black colour, occurs massive, and in balls, is soft, not very brittle, easily frangible, and not very heavy.

2. Glossy alum-slate is of an intermediate colour, between blueish and iron-black; occurs massive, with a shining semi-metallic lustre, and in other respects resembles the former. It is found in beds and strata in Saxony, France, Scotland, and Hungary; and affords considerable quantities of alum.

Sixteenth species. Bituminous Shale

Is of a brownish-black colour, and occurs massive. Internally, its lustre is glimmering; it is very soft, rather mild, feels rather greasy, is easily frangible, and not particularly heavy.

It is found with clay-slate in the coal formation, in Bohemia, England, Scotland, and other coal countries.

Seventeenth species. Drawing Slate, or Black Chalk.

Its colour is a greyish-black, with a tinge of blue; it occurs massive, is opaque, colours and writes, is soft, mild, easily frangible, feels meagre but fine, and is rather light.

It is found in primitive mountains in France, Germany, Iceland, Scotland, and the Hebrides. When of a middling degree of hardness, it is used for drawing.

Eighteenth species. Whet-Slate.

The common colour is greenish-grey; it is massive; internally, weakly glimmering, semi-hard, feels rather greasy, and is not particularly brittle or heavy. It occurs in primitive mountains in Saxony, Bohemia, and the Levant. When cut and polished, it is used for sharpening knives and tools.

Nineteenth species. Clay-Slate.

Its principal colour is grey, of which there are many varieties. It occurs massive; internally, its colour is glistening, the substance opaque, soft, pretty easily frangible. It is found in vast strata in primitive and transition mountains in many different countries, but particularly in Scotland. When split into thin and firm tables, it is used for roofing houses, and other purposes.

Twentieth species. Lepidolite.

Its colour is a kind of peach-blossom, red, verging on lilac-blue, and occurs massive. Its internal lustre is glistening; it is translucent, soft, easily frangible, and easily melts before the blowpipe. Hitherto it has only been found in Moravia, where it lies in gneiss.

Twenty-first species. Mica, or Glimmer.

Its common colour is grey, of great variety of shades. It occurs massive, disseminated in thin tables and layers in other stones, and chrystallized either in equilateral six-sided tables, or in six-sided prisms. The surface of the chrystals is splendent; internally, shining and splendent. In thin plates, it is transparent; but in larger masses only translucent on the edges. It is semi-hard, feels smooth, but not greasy, elastically flexible, and more or less easily frangible.

It forms one of the constituent parts of granite, gneiss, and mica slate, and is almost peculiar to the primitive mountains. It was formerly used instead of glass, for windows and lanterns. Fig. 16.

Twenty-second species. Pot-Stone.

Its colour is a greenish-grey, of different degrees of intensity; is massive; lustre, internally, glistening and pearly, translucent on the edges; soft, feels greasy, and is very difficultly frangible.

It occurs in beds, or is indular; and is found in the country of the Grisons, in Saxony, and probably in Hudson's-bay, and is nearly allied to indurated talc.

Twenty-third species. Chlorite,

Which see.

Twenty-fourth species. Hornblende,

Which see. See also fig. 17.

Twenty-fifth species. Basalt.

The usual colour is greyish-black, of various degrees of intensity. It occurs massive, in blunt and rolled pieces, and sometimes vesicular. Internally, it is commonly dull. It is usually found in distinct concretions, which are generally columnar, and sometimes upwards of 100 feet in length. Commonly opaque, semi-hard, brittle, very difficultly frangible, melts without addition, and is almost exclusively confined to the floetz trap formation. It occurs in strata, beds, and veins, in almost every quarter of the globe, and is very abundant in Scotland, Ireland, and in other parts of the British European dominions. It is useful for building, as a touch-stone, as a flux, and in glass manufactures.

Twenty-sixth species. Wacce.

The colour is a greenish-grey, of various degrees of intensity. It occurs massive and vesicular, is dull, somewhat glimmering, opaque, usually soft, more or less easily frangible, and not particularly heavy.

It is said to belong exclusively to the floetz trap formation, where it occurs in beds and above clay, and also in veins. It is found in Saxony, Bohemia, and Sweden.

Twenty-seventh species. Clink-Stone

Is commonly of a dark greenish-grey colour, always massive, and occurring in irregular columns, and tabular distinct concretions. It is usually translucent on the edges, brittle, easily frangible, and when struck with a hammer, sounds like a piece of metal.

It is said to belong to the floetz trap formation, and generally rests on basalt. It is found in Lusatia, Bohemia, South America, and in the isle of Lambash, in the frith of Clyde.

Twenty-eighth species. Lava

Is divided into two sub-species.

1. Slag lava is of a greyish-black colour, passing into other shades. Externally, it is spotted, occurs vesicular and knotty, is generally opaque, semi-hard, brittle, easily frangible, and not particularly heavy.

2. Foam lava is of a dark greenish-grey colour, occurs small and fine, vesicular; externally, glimmering, slightly translucent on the edges, brittle, easily frangible, and light. It has often been confounded with pumice-stone, from which, however, it differs very much. On account of its lightness, it is used with advantage in arching vaults, and other kinds of building.

Twenty-ninth species. Green Earth.

Its colour is a celaden green, of various degrees of intensity. It occurs massive, in angular and globular pieces, and also disseminated. Internally, it is dull, streak glistening, very soft, easily frangible, and light.

It is principally found in amygdaloid, in Saxony, Bohemia, Scotland, and other places, and is used by painters.

Thirtieth species. Lithomage

Is divided into two sub-species.

1. Friable lithomage, or rockmarrow, is snow-white, or yellowish-white, occurs massive, as a crust, and disseminated; is generally coherent, feels greasy, and adheres to the tongue. Is found in tin veins, in Saxony.

2. Indurated lithomage is most commonly white, of which it presents several varieties; is massive; internally, dull; streak shining, very soft, easily frangible, feels greasy, and adheres strongly to the tongue. It occurs in veins of porphyry, &c. in Saxony, Bohemia, Bavaria, &c.

Thirty-first species. Rock Soap

Is of a brownish or pitch-black colour,

massive and disseminated, dull, opaque, does not soil, writes like drawing-slate, is easily frangible, and adheres strongly to the tongue.

It is found imbedded in rocks of the floetz trap formation, in Poland, and in the isle of Sky, but is very rare, and found only in small quantities.

Thirty-second species. Yellow Earth.

The colour is ochre-yellow, of different degrees of intensity; it is massive, streak somewhat shining, soils, writes, is very soft, adheres pretty strongly to the tongue, and feels somewhat greasy. It occurs in beds with iron-stone, in Upper Saxony, and is employed as a pigment.

To the clay genus, likewise, belong adhesive slate, float-stone, pinite, and umber, which may be considered as recent discoveries.

FIFTH GENUS.

TALC *Genus.*

First species. Bole.

Its colour is cream-yellow, passing into various other shades; is commonly massive, very soft, easily frangible, feels greasy, gives a shining streak, adheres to the tongue, and is light. It occurs in rocks belonging to the newest floetz trap formation, and is found in beds of wacce or basalt, in Silesia, Italy, &c. It was formerly employed in medicine, but is now used only as a pigment.

Second species. Native Talc Earth.

The colour is yellowish-grey, passing into cream-yellow. It occurs massive, tuberose, and of other shapes; is internally dull, almost opaque, soft, frangible without much difficulty, and adheres a little to the tongue.

It is found in beds of serpentine, but only hitherto in Moravia.

Third species. Meerschaum.

The usual colour is yellowish-white. It occurs massive, is internally dull, opaque, streak shining, is soft, adheres strongly to the tongue, feels a little greasy, and is nearly swimming. It is principally found in Natolia, in Samos, Hungary, Moravia, Spain, and America. It is much used in the manufacture of heads of tobacco-pipes. It is said that the Turks eat it as a medicine.

Fourth species. Fuller's Earth.

The colours are greenish-white, grey, olive, and oil-green. It is massive; internally dull, usually opaque, gives a shining streak, is very soft, feels greasy, and is not particularly heavy.

It is found in different situations in England, Saxony, Alsace, and Sweden; and is of essential use in cleansing woollen cloth, from which property it receives its name.

Fifth species. Neaphrite,

Which see.

Sixth species. Steatite.

The principal colour is white, of which it presents many varieties. It occurs massive, disseminated, in crusts, and chrystallized in six-sided prisms. Internally it is dull, streak shining, very soft, rather difficultly frangible, and feels greasy.

It is found in beds and veins in serpentine in Norway, Sweden, Saxony, England, Scotland, and China. It is used in the manufacture of porcelain, and for other purposes.

Seventh species. Serpentine,

Which see.

Eighth species. Schiller-Stone.

Its colour is olive-green, usually disseminated and massive; lustre shining, is soft, slightly brittle, and easily frangible. It occurs imbedded in serpentine, and is found in the Harz, in Saxony, Cornwall, and Ayrshire. It is often confounded with Labradore hornblende.

Ninth species. Talc.

This is divided into three sub-species.

1. Earthy talc is of an intermediate colour between greenish-white and light greenish-grey; friable, strongly glimmering, soils a little, feels rather greasy, and occurs in tin veins near Freyberg in Saxony.

2. Common, or Venetian talc, is principally of an apple-green colour, massive and disseminated, and in delicate and small tabular chrystals. It is almost always splendent and shining, translucent, in thin leaves transparent, flexible, but not elastic; soft, easily frangible, feels very greasy, and approaches to light.

It is almost wholly confined to the primitive mountains, where it is found imbedded in serpentine, and also in veins. It is found in the Tyrolese Alps, in Switzerland, and in Saxony.

3. Indurated talc is of a greenish-grey colour, of various degrees of intensity, occurs massive, is shining, passing to glistening, strongly translucent on the edges, soft, feels rather greasy, and is frangible without particular difficulty. It is found in primitive mountains in Tyrol, Austria, Scotland, and the Shetland isles.

Tenth species. Asbest.

See ASBESTOS.

Eleventh species. Cyanite,

Which see.

Twelfth species. Actynolite

Is divided into the following sub-species:

1. Asbestous actynolite is of a greenish-grey colour, occurs massive, disseminated, and in capillary chrystals; is internally glistening, translucent on the edges, soft, brittle, not easily frangible, nor particularly heavy. It is found in mineral beds in Saxony, and other parts of Germany.

2. Common actynolite is generally of a green leek-colour, passing into other shades of the same; it occurs massive, and likewise chrystallized in very oblique six-sided prisms, is splendent externally, semi-hard, rather brittle, and not easily frangible.

It is found in beds in primitive mountains, in Saxony, Switzerland, Norway, and Scotland.

3. Glassy actynolite is principally of a mountain-green colour, of various degrees of intensity; occurs massive, or in thin six-sided acicular chrystals, is shining and vitreous, strongly translucent, brittle, easily frangible, semi-hard, and is found in similar situations with the preceding.

Thirteenth species. Tremolite.

This is divided into the following sub-species:

1. Asbestous tremolite is of a whitish colour with a tinge of yellow, grey, red, or green: it occurs massive, and in capillary and acicular chrystals; internally glistening, very soft, easily frangible, and translucent on the edges.

2. Common tremolite is nearly of the same colour as the preceding, occurs massive, and in long and very oblique four-sided prisms: internally, is shining and glistening, translucent and semi-transparent, semi-hard, and pretty easily frangible.

3. Glassy tremolite is yellowish, reddish, greyish, and greenish-white; occurs massive, and chrystallized. Internally, is shining and pearly; is composed of very thin prismatic concretions, which are again collected into very thick prismatic concretions. It is translucent, brittle, and pretty easily frangible, and is said to emit a phosphoric light when rubbed in the dark.

Tremolite is principally found imbedded in primitive mountains, particularly the mountains of Tremola, in Switzerland. It is also found in different parts of Germany, and in Scotland.

Sahlite, lately discovered in Sweden, likewise belongs to the talc genus.

SIXTH GENUS.

CALC *Genus.*

First species. Rock Milk.

Its colour is yellowish-white; it is composed of dully, dusty particles generally weakly cohering, feels meagre yet fine, soils very much, and is very light. It is found in fissures and holes of mountains composed of floetz lime-stone, in Switzerland.

Second species. Chalk.

Its colour is principally all yellowish-white: it occurs massive, disseminated, and as crust over flint. Internally, is dull, opaque, soils, writes, soft, sometimes very soft, very easily frangible, feels meagre, and rather rough; effervesces strongly with acids, and is found principally on the sea-coast, though the Chiltern range in England is wholly composed of it. It is used for polishing and cleansing metals, glass, &c. and in some places as a manure, and cement in building.

Third species. Lime-Stone

Is divided into several sub-species:

1. Compact lime-stone is of two varieties, common compact lime-stone, and roe-stone. The former is generally of a grey colour, but is frequently veined, zoned, striped, or clouded; occurs massive, and in rolled pieces; is translucent on the edges, semi-hard, brittle, pretty easily frangible; is almost entirely confined, like lime in general, to the floetz mountains; occurs in sand, stone, and coal formations, in England, Scotland, and many other countries; and is frequently used for building or making roads, or, when burnt, for manure and cement.

The latter, or roe-stone, is of a chesnut-brown colour, is massive; internally dull, composed of small and fine-grained globular distinct concretions; semihard, brittle, not very easily frangible; occurs in beds in considerable quantities in Saxony, and is solely used for manure, for which its admixture with marl admirably fits it.

2. Foliated limestone is likewise of two kinds, granular limestone, and calc spar (figs. 18. and 19.). The former is commonly whitish, but presents many varieties of that colour; is massive, occurs almost always in

granular distinct concretions, is more or less translucent, semihard, brittle, easily frangible, is peculiar to the primitive and transitive mountains, and is chiefly found in Italy, whence it is distributed over Europe, for the purpose of statuary. The white marble of Paros, or granular limestone, has long been celebrated. Scotland furnishes some beautiful varieties of marbles, whose uses are well-known.

The latter, or calc spar, is principally white, but has many shades. It occurs massive, disseminated, and chrystallized, either in six-sided prisms, or three-sided prisms. The lustre alternates from splendent to shining and glistening, and is most commonly vitreous. The massive varieties are translucent, and sometimes even transparent. It is found veinigenous in almost every rock from granite to the newest floetz trap, occurs in a great variety of mineral veins, and is very universally disseminated, but is found particularly beautiful in Derbyshire, in Ireland, Saxony, France, and Spain.

3. Fibrous limestone, is of two varieties, common fibrous limestone, and fibrous limestone, or calc sinter. The former is commonly greyish, reddish, or yellowish-white; massive, lustre glistening, fragments splintery, more or less translucent, semihard, and occurs only in small veins.

The latter, or calc sinter, is principally white, of which it exhibits several beautiful varieties; occurs massive, and also in many particular external forms; internally is glimmering and pearly. It is commonly found in curved lamellar distinct concretions, is more or less translucent, semihard, brittle, and easily frangible; it is discovered in almost every limestone country. The grotto of Antiparos, and similar situations, afford striking instances of calc sinter. It is the alabaster of the ancients, and is still used in statuary.

4. Pea-stone is commonly yellowish-white, massive, internally dull, opaque or translucent on the edges; soft, very easily frangible; and is found in great masses in the vicinity of the hot springs at Carlsbad in Bohemia. It is composed of spherically round distinct concretions. All the varieties of limestone effervesce with acids.

Fourth species. Schaum, or foaming earth,

Is principally of a light yellowish colour; occurs massive and disseminated; is intermediate between shining and glistening; presents large, coarse, small, and fine-grained distinct concretions; is generally opaque, soft, completely friable; feels fine, but not greasy, and cracks a little. It is found in cavities of the oldest floetz limetone in Thuringia, and in the north of Ireland.

Fifth species. Slate spar.

Its colour milky, and greenish or reddish-white; occurs massive; lustre intermediate between shining and glistening, and completely pearly; fragments slaty, translucent, soft, and pretty easily frangible. It is found in limestone-beds in primitive mountains, and is produced in Norway, Saxony, and Cornwall.

Sixth species. Brown spar.

This is divided into the following sub-species:

1. Foliated brown spar, is principally white and red, with several varieties of each. It occurs massive, globular, with tabular impressions, and frequently chrystallized, externally shining, internally alternating from shining to splendent. It is found in granular distinct concretions of all magnitudes; is more or less translucent, semihard; a little difficultly frangible, and occurs in veins generally accompanied with calc spar, &c. in the mines of Norway, France, Germany, England, and other countries.

2. Fibrous brown spar is of a flesh-red, passing into rose-red; occurs massive, lustre glistening, fragments splintery, in other respects resembling the preceding. Hitherto it has been found only in Hungary and Transylvania.

Seventh species. Rhomb spar.

Its colours are yellowish and greyish-white; occurs only in regular middle-sized rhombs; lustre splendent, generally intermediate between translucent and semitransparent; is semihard, brittle, easily frangible, and is found imbedded in rocks belonging to the talc genus in Switzerland, Sweden, and on the banks of Loch-lomond in Scotland.

Eight species. Schaalstone.

The most common colour is greyish-white; it occurs massive, is shining and nearly pearly, translucent, pretty hard, brittle, easily frangible, and has been hitherto found only in the Bannat of Tameswar, accompanied by copper ore.

Ninth species. Stink-stone.

Its colour is wood-brown, passing into various other shades. It occurs massive, and sometimes disseminated through gyps, is dull or glimmering internally, translucent on the edges, rather soft, easily frangible, and when rubbed, emits an urinous smell. It is found in considerable quantities in the district of Mansfield in Thuringia.

Tenth species. Marle,

Which see.

Eleventh species. Bituminous marle slate.

Its colour is intermediate between greyish and brownish-black; it is massive, from glimmering to shining, fragments slaty, usually soft, not very brittle, easily frangible, and streak shining. It is found in beds along with the oldest floetz limestone, and contains much copper intermixed with it, on account of which it is usually smelted in Thuringia.

Twelfth species. Calc tuff.

The colour is yellowish-grey; it is generally perforated or marked with the impressions of other substances, also amorphous, ramose, and corroded. Internally dull, substance opaque, soft, easily frangible, and approaching to swimming. It occurs in alluvial land, and is found in Thuringia, at Gotha, and other places in Germany.

Thirteenth species. Arragone.

The principal colours are greenish-grey, and iron-grey. It occurs chrystallized in perfect equiangular six-sided prisms; the lustre is glistening, passing into shining, and is vitreous; it is semihard, brittle, not particularly heavy, and plurpluresces a little. It was first discovered in the province of Arragon, whence its name, imbedded in gyps, but has since been found in some other countries of the continent.

Fourteenth species. Appatite.

The usual colours are white, green, blue, and red; it generally occurs chrystallized, the radical form of which is the equiangular six-sided prism. Externally it is splendent, internally shining and resinous. It is commonly transparent, semihard, brittle, easily frangible, and occurs in tin veins in Saxony, Bohemia, and in Cornwall. It has been confounded with schorl, &c. Fig. 20.

Fifteenth species. Asparagus or spargel stone.

The principal colour is asparagus-green; it occurs only chrystallized in equiangular six-sided prisms, is internally shining, most frequently translucent, semihard, easily frangible, and brittle. Hitherto it has been found only in Murcia in Spain, though supposed to be produced in Norway. It is nearly allied to appatite. Fig. 21.

Sixteenth species. Boracite.

Its colours are yellowish, smoke and greyish white, passing to asparagus-green; it occurs in chrystallized cubes, with the edges and angles truncated, internally shining, commonly semitransparent, semihard, brittle, and easily frangible. Hitherto it has been discovered only at Luneburg in Hanover. Fig. 22.

Seventeenth species. Fluor,

Which see, also fig. 23.

Eighteenth species. Gyps.

This is divided into the following sub-species:

1. Gyps earth is of a yellowish-white colour, passing into some allied shades, is intermediate between fine scaly and dusky, dull and feebly glimmering, soils a little, feels meagre but soft and fine, and is light. It is found, though rarely, in gyps countries, and is formed in the same manner as rock milk. It is used as a manure.

2. Compact gyps, is commonly ash-grey, passing into smoke and yellowish-grey, is massive, internally dull, feebly translucent on the edges, very soft, frangible without great difficulty, and is employed in architecture and sculpture, under the name of alabaster.

3. Foliated gyps is commonly white, grey, or red, presenting spotted, striped, and veined colour delineations. It occurs massive, and in blunt-edged pieces, but seldom in chrystals. Internally it alternates from shining and glistening to glimmering, is translucent and duplicating, very soft, and not particularly difficultly frangible. It has been confounded with granular limestone.

4. Fibrous gyps is principally white, grey, and red, with various shades of each. It occurs massive and dentiform, the internal lustre is usually glistening and pearly, commonly semitransparent and translucent, very soft, and easily frangible.

Fossils belonging to the gyps formation, occupy different situations. They are found in Switzerland, Thuringia, Derbyshire, Cornwall, Moffat in Scotland, and other places.

Gyps, when burnt, forms an excellent cement, and is used for many ornamental purposes.

Nineteenth species. Selenite.

Its principal colour is snow-white, passing into other neighbouring shades: is generally massive, but not unfrequently chrystallized in pretty oblique six-sided prisms, the chrystals seldom large, but internally shining and splendent. Fig. 24.

Selenite is completely transparent, soft, somewhat flexible, not very frangible, and is found in the oldest gyps formation, in single chrystals in clay beds in the newest formation, and in other situations. It is common in Thuringia, at Montmartre near Paris, Shotover near Oxford, and in the isle of Sheppy. It is employed in taking the most delicate impressions, for crayons and other purposes.

Twentieth species. Cube spar.

The colour is milk-white with various allied shades. It is massive, occurring in large, coarse, and small ground distinct concretions. The lustre is shining, passing into splendent, translucent, softish, very easily frangible, and not particularly heavy. It is found in salt rocks in Salzbourg.

To the calc genus are also referred phosphorite, which forms a great bed in Estremadura in Spain; and the anhydrite, found in the duchy of Wirtemberg.

Seventh genus.

Baryte *Genus.*

First species. Witherite

Is commonly of a light yellowish-grey colour, generally massive, but sometimes chrystallized in six-sided prisms, or double six-sided pyramids. The lustre of the principal fracture is shining; the fragments generally wedge-shaped. It is translucent, somewhat semihard, brittle, easily frangible, and pretty heavy. Figs. 25 and 26.

It melts, without addition, before the blowpipe, into a white enamel, and occurs in veins along with heavy spar, lead-glance, &c. at Anglesark in Lancashire. Combined with muriatic acid, it may be used in medicine, though a very active poison of itself.

Second species. Heavy spar or baryte.

See Barytes.

Eighth genus.

Strontian *genus.*

First species. Strontian.

The usual colour is intermediate between asparagus and apple-green; it occurs most commonly massive, but sometimes chrystallized in a circular six-sided prism. The chrystals are scopiformly and manipularly aggregated. The lustre of the principal fracture is shining, of the cross fracture glistening. It is translucent in a greater or less degree, soft and semihard, brittle, easily frangible, dissolves in acids with effervescence, and occurs along with lead-glance, heavy spar, &c. at Strontian in Argyleshire, the only place where it has yet been found.

Second species. Celestine

Is divided into two sub-species:

1. Fibrous celestine, is of an intermediate colour, between indigo-blue and blueish-grey; it occurs massive and in plates, and also chrystallized, shewing a tendency to prismatic distinct concretions; is translucent, soft or semi-hard, easily frangible, and pretty heavy. It is found in Pennsylvania and in France.

2. Foliated celestine, is of a milky-white colour, falling into blue; it occurs massive, and also chrystallized in six-sided tables intersecting each other. It has a glistening lustre, is strongly translucent, softish, not particularly brittle, easily frangible, and hard. It occurs sometimes in sulphur beds, and is found very finely chrystallized in Sicily, and likewise near Bristol. Fig. 27.

CLASS II.

Fossil Salts.

The substances included in this class are confined to those which are found in a natural state only; and the greater part of them appear to be formed by the agency of water, air, &c.

The distinguishing characters of fossil salts are, their taste and easy solution. They resemble each other so closely, that the term *saline consistence* is used to express whatever relates to hardness, tenacity, and frangibility.

First species. Natron, or *Natural Soda.*

It may be divided into the two following sub-species:

1. Common natron, is of a yellowish or greyish-white colour, occurs in fine flakes or in dusty particles, has a sharp alkaline taste, effervesces with nitric acid, is easily soluble in water, and strikes blue vegetable tinctures green. It occurs as an efflorescence in the surface of soil, or on the sides and bottoms of lakes that occasionally become dry. It is found in very large quantities in Hungary, Bohemia, and Egypt, and in many other countries of the Old World.

2. Radiated natron, or natural soda, is of a greyish or yellowish-white colour, occurs in crusts or chrystallized in capillary or acicular chrystals, is glistening and translucent, and is found in large quantities in the province of Sukana in Barbary, and in Southern Africa.

Natron is principally employed in the manufacture of glass, soap, and for washing. It is also used as a flux after being purified.

Second species. Natural nitre.

The colour is greyish or yellowish-white, approaching to snow-white; it is flaky, sometimes verges to solid and massive, is of a saline consistence, and tastes saltly cooling. Placed on hot iron, it hisses and detonates; is usually found in thin crusts on the surface of the soil at particular seasons of the year, particularly in hot climates. It is also met with in various countries of Europe, and is much used in making gunpowder, in medicine, and the arts. The greatest part, however, employed for those purposes, is an artificial preparation from the refuse of animal and vegetable bodies undergoing putrefaction, and mixed with calcareous and other earth.

Third species. Natural Rock-salt

Is divided into two sub-species:

1. Rock or stone-salt, which is of two kinds, foliated and fibrous. The former is commonly of a white or grey colour, occurs massive and disseminated, and also chrystallized in cubes; in general is strongly translucent, rather hard, easily frangible, and feels somewhat greasy. The latter is greyish, yellowish, and snow-white; occurs massive, is strongly translucent, verging to semitransparent, decrepitates when laid on burning coals, and is found in beds lying over the first or oldest floetz trap formation. It forms whole hills at Cordova in Spain, is found also in Germany, and almost every country in the world. At Nantwich in Cheshire it has long been dug. Its use is as general as its dissemination. It is employed as a daily seasoning for our food, as a manure, in various manufactures, and for purposes too numerous to mention.

2. Lake-salt occurs either in thin plates, which are formed on the surface of salt-lakes, or in grains at their bottom. It is translucent, and of a saline consistence. It is found in Cyprus, near the Caspian Sea, and in various parts of Africa.

Fourth species. Natural sal ammoniac.

The colour is commonly greyish or yellowish-white. It is of a saline consistence, and is flaky, with an urinous taste. It is sometimes found massive, stalactitic, tuberose, botryoidal, and chrystallized. It is the product of volcanoes and pseudo-volcanoes, and is found in Italy, Sicily, in the vicinity of inflamed beds of coal both in England and Scotland, and in several countries of Asia.

Fifth species. Natural Epsom salt.

Colour a greyish-white. It occurs in capillary efflorescences, and is mealy or flaky, of a saline consistence, and taste saltly bitter. It is found as an efflorescence on clayey stones or gyps rocks, at Sena, at Solfatara, in Hungary, and Bohemia. It is also contained in many mineral springs, particularly those of Epsom, whence it derives its name. Epsom salts are much used as an easy purgative. Considerable quantities of magnesia may be obtained from them.

Sixth species. Natural Glauber salt.

The colour is usually greyish and yellowish-white. It occurs in the form of mealy efflorescences, in crusts, and sometimes chrystallized in acicular and in six-sided prismatic chrystals. Internally it is shining, with a vitreous lustre, is soft, brittle, easily frangible, and has a cooling but a saltly bitter taste.

It is found on the borders of salt-lakes, on moorish ground, on old and new-built walls in different countries of Europe, Asia, and Africa, and is used as a purgative medicine, and in some places as a substitute for soda in the manufacture of white glass.

Seventh species. Natural alum

Is of a yellowish or greyish-white colour; occurs as a mealy efflorescence, or in delicate capillary chrystals; has a sweetish astringent taste, and is produced in various situations in Scotland, Germany, Italy, Spain, Sweden, and in Egypt.

Alum is employed as a mordant in dyeing, in the manufacture of leather, as a medicine, for preventing wood from catching fire, and for preserving animal substances from putrefaction.

Eighth species. Hair salt.

The principal colours are snow, yellowish, and greyish-white. It occurs in delicate capillary chrystals, has a saline consistence, and a sweetish astringent taste.

Hair salt is found in different mine countries on the continent, at Whitehaven in England, and near Paisley in Scotland, and bears a striking resemblance to fibrous gyps.

Ninth species. Rock butter.

The colour is light-yellow or greyish-white. It occurs massive and tuberose, is translucent, has a saline consistence, or sweetish-sour astringent taste, and feels a little greasy. It oozes out of fissures of rocks of alum slate, and is found in Lusatia, Thuringia, Denmark, Siberia, and near Paisley in Scotland.

Tenth species. Natural vitriol

Is divided into the three following sub-species:

1. Iron vitriol, is commonly of an emerald and verdigris green. It occurs massive, tuberose, stalactitic, and chrystallized in different figures; is splendent and vitreous, has a saline consistence, and a sourish astringent taste. It is found usually along with iron pyrites, by the decomposition of which it is formed, in different countries of continental Europe, in many of the English mines, and in America. It is employed to dye linen yellow, and wool and silk black, in the preparation of ink, as a paint, &c.

2. Copper vitriol, is usually of a dark sky-blue colour. It occurs massive, disseminated, stalactitic, dentiform, and chrystallized; is translucent, soft, very brittle, and has a styptic taste. It is found in various mining countries, in Wicklow, and in Anglesea. It is used in cotton and linen printing, and when prepared is employed by painters.

3. Zinc vitriol, is of a greyish, yellowish, reddish, and greenish-white colour. It occurs tuberose, stalactitic, and coralloidal, is translucent, of a saline consistence, and a styptic taste. It is produced most abundantly where much blende occurs, and is found in Austria, Hungary, and Sweden.

Here it must be remarked, that borax, though so well known by name, is without a place in the Wernerian system, as it is uncertain whether or not it occurs in a solid state. It is most probable that it occurs only in solution in certain lakes. See Borax.

The new genus stallite, of which only one species, cryolite, has been found in Greenland, seems properly to come under this head.

CLASS III.

Inflammable Fossils.

Fossils belonging to this class are light, brittle, mostly opaque, yellow, brown, or black, seldom chrystallized, and never feel cold. They are more nearly allied to the metallic than to the earthy or saline classes.

First Genus.

Sulphur *Genus.*

First species. Natural sulphur.

It contains the two following sub-species:

1. Common natural sulphur, is of the colour the name expresses, but of different degrees of intensity. It occurs massive, disseminated, and chrystallized in octahedrons or double six-sided pyramids, is internally between shining and glistening, translucent, in chrystals frequently transparent, very soft, easily frangible, and light.

It is found in masses in gyps, in veins that traverse primitive rocks, in nests of limestone, and in other situations, and is produced in every quarter of the world, though in the British dominions it seems to be confined to Ireland.

2. Volcanic natural sulphur is of the colour the name imports, but with a considerable tinge of green. It occurs corroded, vesicular, perforated, amorphous, and sometimes as a sublimate in flowers, is glistening and resinous, and translucent in a slight degree. It is found only in volcanic countries, and among lava, but is produced in great abundance; and is employed in medicine, in the composition of gunpowder, and as a vapour in whitening wool and silk.

Second Genus.

Bituminous *Genus.* See Bitumens.

First species. Brown coal. See Coal.

Fourth Genus.

Graphite *Genus.*

First species. Glance coal.

This is divided into two sub-species:

1. Conchoidal glance coal, is of an iron-black colour, of different degrees of intensity, occurs massive and vesicular, internally shining, bordering sometimes on semihard, brittle, easily frangible, and light. It burns without flame or smell, and has hitherto been found only in the newest floetz mass formation, accompanied with other kinds of coal, at Meissner in Hessia. The fracture is conchoidal.

2. Slaty glance coal, is of a dark iron-black colour, occurs massive, is shining and glistening, soft, very easily frangible, light, and intermediate between sectile and brittle. It is found imbeded in masses, beds, and veins, in primitive, transitive, and floetz rocks, and is produced in Spain, Savoy, Saxony, Bohemia, and in the isle of Arran in Scotland. Its principal fracture is more or less slaty.

Second species. Graphite.

This contains two sub-species:

1. Scaly graphite, is commonly of a dark steel-grey colour. It occurs massive and disseminated, is usually glistening, fracture scaly-foliated, is very soft, perfectly sectile, writes and soils, feels very greasy, and is rather difficultly frangible.

2. Compact graphite, is rather blacker than the preceding, is internally glimmering with a metallic lustre, fracture fine-grained, in other respects agreeing with the preceding. It usually occurs in beds, and is found near Keswick in England, in Ayrshire in Scotland, and in various other parts of Europe, Asia, and Africa. The finer kinds are first boiled in oil, and then cut into pencils. The coarser parts and sawings are melted with sulphur, and then cast into coarse pencils for the use of artificers. It is likewise applied to various other purposes, under the vulgar name of black lead.

Third species. Mineral charcoal.

The colour is a greyish-black. It occurs in small angular and somewhat cubical-shaped pieces, is glimmering, with a silky lustre, soils strongly, is soft, and light. It is found in thin layers in different kinds of coal, and is widely disseminated.

Fifth Genus.

Resin *Genus.* See Resins.

First species. Amber.

This is divided into the two following sub-species:

1. White amber, is of a straw-yellowish colour. It occurs massive, and sometimes associated with the following sub-species, is glistening with a resinous lustre, fracture conchoidal, and simply translucent.

2. Yellow amber, is of a wax-yellow colour, passing into several neighbouring shades. It occurs always in indeterminately angular blunt-edged pieces, is externally dull, internally splendent, with a vitreous and resinous lustre. It is transparent, soft, rather brittle, pretty easily frangible, light, and swimming. It burns with a yellow-coloured flame, emitting an agreeable odour; when rubbed, it acquires a strong negative electrical virtue; is found in layers of bituminous wood, and in moor coal, on sandy sea-shores, and frequently floating on the sea. It is chiefly produced on the coasts of Prussia, in Sweden, Norway, &c. and according to some, has been found in the alluvial land near London. It admits of a fine polish, and is cut into necklaces, bracelets, snuff-boxes, and various other articles. The oil and acid obtained from it are used in medicine.

Second species. Honey-stone.

See Mellite.

CLASS IV.

Metallic Fossils.

First, Platina *Genus.*

First species. Native platina.

The colour is very light steel-grey, approaching to silver-white. It occurs in flat, smooth, and smallish grains, externally shining, lustre metallic, intermediate between semihard and soft, completely malleable, pretty flexible, and very heavy, its specific gravity being about 15.6.

Platina is the least fusible of metals, and does not amalgamate with mercury. It has hitherto been found only in sand accompanied with other metals, and is produced in South America, and probably also in St. Domingo and Barbadoes. From the peculiar qualities it possesses of resisting the action of many salts, of remaining unaltered in the air, and of receiving a fine polish, it has been rendered subservient to several purposes in chemistry and the arts. See Platina.

Second Genus. *Gold.*

First species. Native gold.

This is divided into three sub-species:

1. Gold-yellow native gold, is of a perfect colour, corresponding to its name. It seldom occurs massive, often disseminated in membranes, in roundish and flattish pieces, in grains, and also chrystallized in cubes, octahedrons, simple three-sided pyramids, garnet dodecahedrons, and acute double eight-sided pyramids. External lustre of the chrystals is splendent; internally it is glimmering, passing into glistening. It is soft, completely malleable, flexile, and uncommonly heavy. It is found in veins, beds, disseminated in rocks, and in grains, in almost every country of the world, but commonly in too small quantities to be collected for use. America and Africa supply the largest quantities.

2. Brass-yellow native gold, is principally of the colour of brass, occurs disseminated, capillary, moss-like, reticulated, and in leaves, also chrystallized in thin six-sided cubes, and is rather lighter than the preceding. It is found in different situations in Bohemia, Transylvania, and Norway.

3. Greyish-yellow native gold, is of a brass-yellow colour falling into steel-grey, occurs in very small flattish grains like platina, and is found with that metal.

Third Genus. *Mercury,* which see.

First species. Native mercury, or quick-silver.

The colour is tin-white; it occurs perfectly fluid in globules, is splendent, and has a metallic lustre, does not wet, feels very cold, and is uncommonly heavy. Before the blow-pipe it is volatilized, without any smell. It is usually found in cinnabar at Idria. It occurs in a compact limestone, and here it is very abundant. It is likewise produced in different parts of Germany, France, Spain, and in very large quantities in Peru.

The uses of quicksilver are multifarious, and cannot be enumerated in this place.

Second species. Natural amalgam.

Fluid or semi-fluid amalgam is of an intermediate colour between tin and silver-white. It occurs in small massive pieces and in balls, also disseminated and chrystallized in different forms. Externally it is shining and splendent, is soft and somewhat fluid; when cut or pressed, it emits a creaking sound like natural amalgam, and is uncommonly heavy.

Third species.. Mercurial horn-ore, or corneous mercury,

Is of an ash-grey colour, of various degrees of intensity; occurs very rarely massive, but commonly in small vesicles, internally chrystallized and splendent. It is soft, sectile, easily frangible, and heavy. It is usually found with the other species of mercury, and is produced in the same countries. It was first discovered in the mines of the Palatinate.

Fourth species. Mercurial liver-ore, or mercurial hepatic ore.

Compact mercurial liver-ore, is of an intermediate colour between dark-red and lead-grey, occurs massive, is glistening and glimmering internally, opaque, soft, sectile, easily frangible, and uncommonly heavy. It is the most common ore of mercury at Friaul in Idria.

Fifth species. Cinnabar.

Dark-red cinnabar, is principally of a perfect cochineal red, occurs massive, disseminated, in blunt-cornered pieces, in membranes, amorphous, dendritic, fruticose, and chrystallized. The chrystals are small, splendent externally, and shining internally. The massive cinnabar is opaque or translucent on the edges, very soft, sectile, easily frangible, and uncommonly heavy.

Bright-red cinnabar is of a lively scarlet-red colour. It occurs massive and disseminated, is internally glimmering, substance opaque, streak shining, soils, is very soft, sectile, very easily frangible, and very heavy. Both belong to the same countries with quicksilver. In Idria, Spain, and Peru, this genus is most abundant. It does not occur in Norway, Sweden, Great Britain, or Ireland. From the ore of cinnabar the greatest part of the mercury used in commerce is obtained.

FOURTH GENUS. *Silver.*

First species. Native Silver.

Common native silver is of the colour the name expresses. It occurs massive, disseminated, in pieces, plates, and membranes, as well as in other forms, besides being chrystallized in cubes, octahedrons, four-sided rectangular prisms, double six-sided pyramids, double three-sided pyramids, and hollow four-sided pyramids. It is soft, perfectly malleable, common flexible, and very heavy when pure. It appears to belong to the newer primitive rocks, where it occurs in veins, and is usually accompanied with heavy spar and quartz.

Second species. Antimonial silver.

The colour is intermediate between tin-white and silver-white. It occurs massive, disseminated, and chrystallized, is externally glistening, internally shining and splendent, with a metallic lustre. It is found in coarse, small, and fine granular distinct concretions, is sectile, not very difficultly frangible, soft, and uncommonly heavy. It contains upwards of 80 parts of silver. It occurs in veins composed of calx, spar, &c. in Spain, Germany, and other countries.

Third species. Arsenical silver.

The colour is tin-white, passing into silver-white. It occurs massive, disseminated, globular, and chrystallized; is softish, sectile, and very heavy. It contains about 12 parts of silver, much arsenic and iron, and is usually found with native arsenic and other minerals in Germany and Spain, but is a rare mineral.

Fourth species. Corneous silver-ore, or horn-ore.

The colour is most frequently a pearl-grey, of all degrees of intensity. It occurs massive, disseminated, in membranes, balls, and also chrystallized in cubes and in acicular and capillary chrystals. It is more or less translucent, soft, perfectly malleable, and heavy. It contains upwards of 60 parts of silver, and is found always in veins. It is widely distributed over the globe, but is most abundant in South America. It is sometimes found in Cornwall, and receives its name from cutting like horn.

Fifth species. Silver-black.

The colour is a blueish-black, whence its name. It occurs massive, disseminated, and in various other forms, of all degrees of consistence, from friable to solid. It gives a shining metallic streak, soils very little, is easily frangible, sectile, and heavy. It is found with silver-glance and horn-ore in Hungary, Bohemia, Norway, and Siberia.

Sixth species. Silver-glance

Is of a dark-blackish lead-grey colour, occurs usually massive, disseminated, in membranes, &c. and also chrystallized in cubes, octahedrons, garnet dodecahedrons, and double eight-sided pyramids. Externally it is shining and glistening; internally it alternates from shining to glistening, and has a metallic lustre. It is soft, completely malleable, pretty flexible, and uncommonly heavy, containing upwards of 80 parts of pure silver; and is found in veins, along with native silver and other minerals, in Hungary, Austria, and other countries of Europe, but more particularly in Mexico and Peru.

Seventh species. Brittle silver-glance.

The colour is intermediate between iron-black and dark lead-grey. It occurs massive, disseminated, in membranes, and frequently chrystallized in equiangular six-sided prisms, and rectangular four-sided tables. Externally it is highly splendent, internally shining and glistening. It is soft, brittle, easily frangible, and uncommonly heavy, containing upwards of 60 parts of silver. It is found always in veins, accompanied with other minerals, and principally in Hungary and Saxony.

Eighth species. Red silver-ore.

Dark-red silver-ore is intermediate between cochineal-red and lead-grey. It occurs massive, disseminated, dendritic, in membranes, and chrystallized in equiangular six-sided prisms. It is externally splendent; internally it alternates from shining to glimmering. The massive varieties are opaque; the chrystallized passing from semi to transparent. It is soft, sectile, easily frangible, and heavy.

This species occurs always in veins, accompanied with other minerals, and is found in Bohemia, Hungary, Norway, and other countries.

Ninth species. White silver-ore.

The colour is a very light lead-grey. It occurs massive and disseminated, has a metallic lustre, a shining streak, is soft, slightly flexible, easily frangible, and heavy. It contains large quantities of lead, sulphur, and antimony, and scarcely 10 parts of silver. It is always found in veins, and chiefly near Freyberg.

Tenth species. Black silver-ore.

The principal colour is iron-black, inclining to steel-grey. It occurs massive, disseminated, and chrystallized in three-sided pyramids. Internally it is shining with a metallic lustre. It is semihard, sectile, easily frangible, and heavy.

FIFTH GENUS. *Copper*, which see.

First species. Native copper.

The colour is copper-red, but frequently tarnished. It occurs massive, disseminated, and in various other forms, besides being chrystallized in cubes, dodecahedrons, &c. It is intermediate between semihard and soft, completely malleable, common flexible, difficultly frangible, and very heavy. It is usually found in veins and sometimes in beds, and is produced in Cornwall, Anglesea, the Shetland islands, and many other countries of Europe, Asia, and America. Copper may be applied to a vast number of useful purposes, and is next to iron the most necessary of metals.

Second species. Copper-glance.

Compact copper-glance is usually of a dark lead-colour, passing into blackish-grey. It occurs massive, disseminated, in membranes, and occasionally chrystallized; externally shining, internally between shining and glistening. It is soft, perfectly sectile, easily frangible, and heavy.

Third species. Variegated copper ore.

Its colour, when dug, is intermediate between copper-red and pinchbeck-brown, but it soon becomes tarnished. It occurs massive, disseminated in plates, membranes, and chrystallized in octahedrons. It is soft, slightly sectile, easily frangible, and heavy; and is found in beds, veins, and rocks of different formations, in Cornwall, and various parts of continental Europe. It yields about 70 parts of pure copper.

Fourth species. Copper pyrites.

When fresh, its colour is brass-yellow, of different shades according to its richness. It occurs massive, disseminated in membranes, &c. and also chrystallized in various figures. Externally it is intermediate between glistening and shining, internally soft; is between semihard and soft, brittle, easily frangible, and heavy.

Fifth species. White copper ore

Is of an intermediate colour between silver-white and bronze-yellow: occurs massive and disseminated; is internally glistening, with a metallic lustre; rather soft, brittle, easily frangible, and heavy. It is found in veins and mineral beds in primitive mountains, and is produced in Cornwall, in different parts of Germany, in Siberia, and in South America; but it is one of the rarest species of copper ore.

Sixth species. Grey copper ore, or Fahl ore.

The most common colour is steel-grey: it occurs massive, disseminated, and also crystallized in tetrahedrons, octahedrons, and garnet dodecahedrons. It is more or less semihard, brittle, easily frangible, and heavy; and is found in the newer primitive rocks, and likewise in transitive and floetz rocks, in several mines of Cornwall, in Germany, Italy, Sweden, Norway, Siberia, and Chili. It is usually smelted on account of the copper it contains.

Seventh species. Copper black.

The colour is usually intermediate between bluish and brownish-black: it occurs massive, or disseminated, and as a coating, to other ores of copper; is always more or less cohering, and heavy, containing from 40 to 50 parts of copper. It is usually found with copper pyrites, &c. and is produced in Silesia, Germany, France, Sweden, Norway, and Siberia. Sometimes it is very beautiful.

Eighth species. Red copper ore.

Compact red copper is usually of a dark cochineal-red colour: occurs massive, in membranes, crowded, amorphous, and also disseminated. Internally it is glimmering, inclining to glistening, with a semimetallic lustre: it is opaque, semihard, brittle, easily frangible, and heavy.

Ninth species. Tile ore.

Earthy tile ore is usually of a red hyacinth colour; massive, disseminated, and incrusting copper pyrites; is intermediate between friable and solid, soils slightly, is almost always coherent, and is heavy. It is found in veins; commonly accompanied with native copper ore and malachite.

Tenth species. Copper azure.

Earthy copper azure is of a smalt-blue colour; usually friable, and disseminated; is composed of dusty particles, does not soil, is chiefly cohering, and approaches to heavy. It is found in small quantities, usually accompanied with malachite and copper green, in different parts of Germany, in Norway, and Siberia.

Eleventh species. Malachite, which see.

Twelfth species. Copper green.

The principal colour is verdigris-green, of different degrees of intensity: it usually occurs massive, disseminated, and coating malachite; is internally shining; more or less transluscent, soft, not very brittle, easily frangible, and intermediate between heavy and not particularly heavy. It is found in the same geognostic situation with malachite, in Cornwall and other countries, but is rare.

Thirteenth species. Iron-shot copper green.

Earthy iron-shot copper green is usually of an olive-green colour: occurs massive, and disseminated; is dull, soils a little, soft, passing into friable, not very brittle, easily frangible, and not particularly heavy.

Fourteenth species. Copper emerald.

The colour is an emerald-green. It occurs in chrystallized six-sided prisms, which are externally and internally shining, with a vitreous lustre, and transluscent. It is semihard, brittle, and not particularly heavy; and is found in the remoter parts of the Russian dominions, and on the Chinese frontiers.

Fifteenth species. Copper mica

Is usually of an emerald-green colour: it occurs massive, disseminated, and occasionally chrystallized in very thin six-sided tables. Externally it is smooth and splendent, internally splendent with a pearly lustre. The massive varieties are transluscent; the chrystallized transparent. It is soft, sectile, not very brittle, nor particularly heavy; and has hitherto been found only in veins in Cornwall, where it passes under the unscientific name of foliatic arseniat of copper.

Sixteenth species. Lenticular ore.

The colour is sky-blue, sometimes passing into verdigris green. It occurs chrystallized in small, flat, double, four-sided pyramids; is externally shining; translucent, soft, rather brittle, and very easily frangible. Hitherto it has been found only in Cornwall.

Seventeenh species. Oliven ore.

Foliated oliven ore is of a perfect olive-green: seldom occurs massive, usually in drusy crusts, and in small chrystals, presenting acute rhomboids, and oblique four-sided prisms. Internally it is glistening, with an adamantine lustre. It is very soft, sectile, and heavy in a low degree; and has hitherto been found only in Cornwall.

SIXTH GENUS. *Iron.*

First species. Native iron

Is of a light steel-grey colour, inclining to silver white: it has hitherto been found only ramose; internally it is intermediate between glimmering and glistening, with a perfect metallic lustre, and a hackly fracture. It is between soft and semihard, perfectly malleable, common flexible, difficultly frangible, and uncommonly heavy. Hitherto it has been found only in loose masses on the surface of the earth, and is a rare production.

Second species. Iron pyrites.

Common iron pyrites is usually of a perfect bronze-yellow colour: it occurs massive, disseminated, in membranes, and also chrystallized in cubes, octahedrons, dodecahedrons, icosahedrons, and leuzite chrystals. It is hard, brittle, and heavy, and when rubbed or struck with steel, emits a strong sulphureous smell. It occurs in almost every kind of mineral repository, but most commonly in granite: its geographic distribution is equally extensive, but it is principally valued on account of the sulphur which may be extracted from it by sublimation.

Third species. Magnetic pyrites

Is of an intermediate colour between bronze-yellow and copper-red: it occurs massive and disseminated; is internally shining, with a metallic lustre, passes from hard to semihard, is brittle, easily frangible, and heavy. It is attracted by the magnet; is found only in primitive mountains, in Caernarvonshire, in several parts of Germany, in Norway, and Siberia; and is used for the same purposes as common pyrites.

Fourth species. Magnetic iron-stone.

Common magnetic iron-stone is of an iron-black colour: is massive, disseminated, and also chrystallized in cubes, octahedrons, and garnet dodecahedrons, and rectangular four-sided prisms. It is externally shining; internally between splendent and glistening, with a metallic lustre; is intermediate between hard and semihard, brittle, and heavy. It occurs most frequently in primitive mountains, and is found in the Shetlands, many parts of Germany, and other countries, particularly Sweden. When pure it affords excellent bar iron.

Fifth species. Iron glance.

Common iron glance is usually of a dark steel-grey colour, with several different shades. It commonly occurs massive and disseminated, and also chrystallized in flat, double, three-sided pyramids, and in double three-sided pyramids. Externally it alternates from splendent to glistening; internally it is most commonly glistening. It is hard, brittle, heavy, and rather difficultly frangible. It occurs in beds and veins in primitive and transitive mountains, and is found in considerable quantities in Sweden and other countries, and affords, when smelted, an excellent malleable iron.

Sixth species. Red iron-stone.

Red iron froth. The colour is intermediate between cherry-red and brownish-red. It occurs commonly friable, massive, sometimes coating and disseminated, and is composed of scaly particles, which are glimmering, and have a semi-metallic lustre. It soils strongly, feels greasy, and is pretty heavy. It is found usually in veins, and chiefly in primitive mountains in Lancashire, Cornwall, Norway, Germany, and Chili, and produces good iron.

Seventh species. Brown iron-stone.

Brown iron froth is of an intermediate colour between steel-grey and clove-brown, and is between friable and solid. It occurs massive, coating, spumous, &c. and is composed of scaly particles, shining and glistening, with a metallic lustre. It soils strongly, feels greasy, and is very light. It is commonly found lining drusy cavities, in brown hematite, in the Shetland isles, in various parts of Germany, and in Chili.

Eighth species. Sparry iron-stone.

The principal colour is a light yellowish-grey, which, on exposure to the air or heat, changes into brown or black. It occurs massive, disseminated, with pyramidal impressions, in plates, and chrystallized. It is found in granular distinct concretions, commonly translucent on the edges, semihard, not very brittle, easily frangible, and heavy. It is chiefly confined to the primitive and floetz mountains, and is produced in small quantities in England, Scotland, and Ireland; but on the continent it is in some places very abundant, and affords an iron which is excellently adapted for steel-making.

Ninth species. Black iron-stone.

Compact black iron-stone, is of an intermediate colour between bluish-black, and dark steel-grey: it occurs massive, tuberose, reniform, &c. is semihard, brittle, easily frangible, and heavy.

Tenth species. Clay iron-stone.

Reddle is of a light brownish-red, passing into cherry-red: it occurs only massive; soils strongly, and writes, is sectile, easily frangible, and rather heavy. It is chiefly found in the newer clay-slate, and is produced pretty abundantly in Germany and Siberia. The coarser varieties are used by the carpenter, the finer by the painter, under the name of red-chalk.

Eleventh species. Bog iron-ore.

Morass ore is of a yellow-brown colour, sometimes friable, sometimes coherent, and occurs massive, corroded, in grains, and tuberose. It soils pretty strongly, feels meagre but fine, and is lightish.

Twelfth species. Blue iron-earth.

When fresh it is whitish, but soon becomes of an indigo-blue colour, of different degrees of intensity; it occurs massive, disseminated, and thinly coating; the particles are dull and dusty; it soils slightly, feels fine, and is lightish. It is found in nests in clay-beds, and other situaions, in the Shetland isles, Iceland, Sweden, and Siberia.

Thirteenth species. Green iron-earth.

Friable green iron-earth is of a siskin-green colour, occurs massive and disseminated, is more or less cohering, soft, fine, easily frangible, and intermediate between particularly heavy and heavy.

Fourteenth species. Cube ore.

The colour is olive-green, of different degrees of intensity; it occurs massive, and chrystallized in small cubes, is translucent, soft, brittle, and not particularly heavy. It is found in veins, but hitherto only in Cornwall.

SEVENTH GENUS. *Lead.*

First species. Lead glance.

Common lead glance is of a fresh lead-grey colour, of different degrees of intensity; it occurs massive, disseminated, in membranes, &c. and also chrystallized in cubes, octahedrons, four-sided prisms, six-sided prisms, and three-sided tables. It is soft, sectile, externally easily frangible, and uncommonly heavy; and is found in veins and beds in primitive, transitive, and floetz mountains, at lead-hills in Lanarkshire, Derbyshire, and several other counties of England, Scotland, and Wales; besides being widely diffused over other parts of the globe. It is most frequently worked as an ore of lead, but sometimes as an ore of silver.

Second species. Blue-lead ore.

Is of an intermediate colour between dark indigo-blue and lead-grey; it occurs massive, and chrystallized in perfect six-sided prisms, is soft, sectile, easily frangible, and heavy, and is found in veins with other minerals of the same class, but is altogether a rare fossil, nor has it hitherto been discovered in Britain.

Third species. Brown-lead ore.

Is of a hair-brown colour of different degrees of intensity; it occurs massive, and chrystallized in six-sided prisms, is feebly translucent, soft, not very brittle, easily frangible, and intermediate between heavy and uncommonly heavy. It is found in veins, accompanied with other minerals, in Bohemia, Hungary, Brittany, and Saxony.

Fourth species. Black-lead ore.

The colour is greyish-black, of different degrees of intensity; it occurs massive, disseminated, and chrystallized in six-sided prisms; externally is usually splendent, internally shining with an adamantine lustre, is rather brittle, easily frangible, and heavy. It is found in veins, and almost always accompanied with other kinds of lead ore, at lead-hills in Scotland, in Bohemia, Saxony, and other mineral countries.

Fifth species. White-lead ore.

The colour is white, but has various shades; it occurs massive, disseminated, in membranes, but most commonly chrystallized in prisms and pyramids, of different figures. Externally, it is specular splendent, internally between splendent and glistening, with an adamantine lustre. It is soft, brittle, very easily frangible, and heavy, and is found in most places where the other species occur, in England, Wales, Scotland, Ireland, &c. Next to lead glance it is the most common of the lead ores, but is seldom in sufficient abundance to become an object to the metallurgist.

Sixth species. Green-lead ore.

Its colour is grass-green, of various shades; it generally occurs chrystallized, in six-sided prisms, is always translucent, soft, rather brittle, very easily frangible, and heavy. It is produced in Scotland and other countries, and is sometimes confounded with the preceding species.

Seventh species. Red-lead ore.

Its general colour is a hyacinth-red; it occurs massive but rarely, sometimes in membranes, but most commonly chrystallized in broad oblique four-sided prisms, is both externally and internally splendent, very soft, between brittle and sectile, easily frangible, and heavy. It is found in veins in gneiss and mica slate, accompanied with other fossils of the same kind, in Austria, Savoy, and Siberia, and on account of its beautiful colour is chiefly used as a pigment.

Eighth species. Yellow-red ore.

Its principal colour is wax-yellow; it is generally chrystallized in rectangular four-sided tables, cubes, octahedrons, equiangular eight-sided tables, and double eight-sided pyramids. Externally, it is shining and smooth, internally glistening, with a resinous lustre; it is translucent, soft, between brittle and sectile, easily frangible, and heavy. It is found in compact lime-stone in Carinthia, and some other countries of the continent.

Ninth species. Lead vitriol, or vitriol of lead.

The colour is yellowish-grey and greyish-white; it occurs only chrystallized in octahedrons of different figures. Externally it is shining, internally splendent, with an adamantine lustre. It is often semi-transparent, rather brittle, and heavy, and is found in Scotland, Anglesea, and Spain.

Tenth species. Lead earth.

Coherent lead earth is usually of a yellowish-grey colour; it occurs massive, is internally glimmering, usually opaque, soft, inclining to sectile, easily frangible, and heavy. It is found in primitive lime-stone in Derbyshire, Scotland, and many other countries.

EIGHTH GENUS. *Tin.*

First species. Tin pyrites.

The colour is intermediate between steel-grey and brass-yellow; it occurs massive and disseminated. Internally is glistening, and has a metallic lustre, is semihard, brittle, easily frangible, and heavy. It melts easily, and has hitherto been found only in Cornwall.

Second species. Tin stone.

The most common colour is blackish-brown; it oecurs massive, disseminated, in rolled pieces, in grains, like sand, but most frequently chrystallized in prisms and pyramids of different figures. Internally it is shining and glistening, it yields a greyish-white streak, is hard, easily frangible, brittle, and very heavy. It is found only in primitive rocks, and is confined to a few situations, like all the tin genus.

Third species. Cornish tin ore, or wood tin.

The most usual colour is hair-brown, of different degrees of intensity; it occurs usually in rolled pieces, sometimes reniform with impressions. It is found usually in large and coarse granular distinct concretions, is opaque, hard, brittle, easily frangible, and uncommonly heavy. It is infusible, and hitherto has only been found in Cornwall in alluvial land, accompanied with tin stone.

NINTH GENUS. *Bismuth.*

First species. Native bismuth.

Its colour is silver-white, with an inclination to red; it occurs massive, disseminated in leaves, reticulated, and chrystallized in small four-sided tables, and in small and indistinct cubes, and three-sided pyramids. It is soft, sectile, rather difficultly frangible, and uncommonly heavy; and is found in veins in primitive mountains in Saxony, and other parts of the continent; but it is doubtful if produced in Britain.

Second species. Bismuth glance.

The colour is a light lead-grey; it occurs massive, disseminated, and in acicular and capillary chrystals; it soils, inclines to sectile, is easily frangible, and heavy. It is found always in veins, and is usually accompanied with native bismuth, chiefly in Saxony, Bohemia, and Hungary.

Third species. Bismuth-ochre.

The colour is a straw-yellow, passing into other neighbouring shades; it is massive and disseminated, opaque, soft, not very brittle, easily frangible, and heavy. This mineral is rare, and seems to be confined to a few places in Saxony and Bohemia.

TENTH GENUS. *Zinc.*

First species. Blende.

Yellow blende is of a dark wax and sulphur yellow colour; it usually occurs massive and disseminated, but is sometimes chrystallized in rectangular four-sided prisms; it is shining and splendent both externally and internally, with an adamantine lustre; is found in large and coarse granular distinct concretions, is usually translucent, semihard, brittle, easily frangible, and heavy. It phosphoresces when rubbed in the dark; occurs most frequently in transitive mountains in Bohemia, and other parts of Germany.

Second species. Calamine.

The general colour is yellowish-grey, which passes into other neighbouring shades; it occurs massive, disseminated, cellular, corroded, &c. and chrystallized in tables, cubes, pyramids, and prisms. Externally the chrystals are splendent and shining; internally, between shining and glimmering. It is usually found in small and fine granular distinct concretions, is semihard, not very brittle, rather difficultly frangible, and heavy; and is produced in beds in a floetz limestone formation, accompanied with iron-ochre, lead-glance, &c. It is met with in all the mine counties of England and Scotland, in Germany, and other parts of the continent; and when purified and roasted, is used for the fabrication of brass, which is a compound of zinc and copper.

ELEVENTH GENUS. *Antimony.*

First species. Native antimony.

The colour is perfect tin-white: it occurs massive, disseminated, reniform, and probably chrystallized; in the fresh fracture it is splendent, and has a metallic lustre. It is found usually in coarse, small, and fine granular distinct concretions, is soft, sectile, easily frangible, and heavy in a low degree. It is produced in veins in Dauphiny and in the Harz, and disseminated in calx-spar in Westermanriland, in Sweden; but is a rare mineral.

Second species. Grey antimony ore.

Compact grey antimony-ore is usually of a light lead-grey colour, occurs massive, disseminated, and occasionally in membranes; internally is shining and glistening with a metallic lustre, is soft, not very heavy, easily frangible, soils, and becomes more shining in the streak. It is found in Sweden and some other countries, but is the rarest sub-species.

Third species. Black antimony ore.

Is of an iron-black colour, occurs only chrystallized in rectangular four-sided tables, is internally shining with a metallic lustre; is soft, rather sectile, and heavy. In Cornwall it is found of peculiar beauty.

Fourth species. Red antimony-ore.

Its colour is cherry-red; it occurs massive, often in membranes, but most frequently in delicate capillary chrystals; both externally and internally it is shining, and has an adamantine lustre. It is found in coarse, small, and longish granular distinct concretions, is opaque, not very brittle, and easily frangible; but is a very rare species.

Fifth species. White antimony ore.

It passes in colour from snow-white to several neighbouring shades; occurs massive and in membranes occasionally, but most commonly chrystallized in rectangular four-sided tables, cubes, and acicular and capillary chrystals. It is found in coarse and small granular distinct concretions, is translucent, soft, rather sectile and heavy. Before the blowpipe, it becomes wholly volatilized. It is found in veins in Bohemia, Hungary, and Saxony.

Sixth species. Antimony-ochre.

The colour is a straw-yellow, of various degrees of intensity; it seldom occurs massive and disseminated, but usually as a coating on chrystals of grey antimony ore. It is dull, soft, not very brittle, nor particularly heavy. It is found always in veins, in different parts of Germany, and is evidently found by the decomposition of grey antimony ore.

TWELFTH GENUS. *Cobalt.*

First species. White cobalt ore.

When fresh fractured the colour is usually tin-white; it occurs massive, disseminated, &c. and also chrystallized in cubes and double four-sided pyramids. It is found in coarse, small, and fine granular distinct concretions; is semihard, brittle, not very difficultly frangible, and heavy. It easily melts before the blowpipe, emits a strong arsenical smell, and yields a white metallic globule. It usually occurs in beds in primitive mountains, and is found in Sweden, Norway, and Silesia.

Second species. Grey cobalt ore.

On the fresh fracture its colour is light steel-grey inclining to white, but it becomes tarnished by exposure; it occurs only massive, disseminated, tubiform and specular; internally it is glimmering or glistening with a metallic lustre, is found in thick and curved lamellar distinct concretions, and is produced in Cornwall, Norway, and various other countries.

Third species. Cobalt glance.

The colour is a silver-white, slightly inclining to reddish: it is commonly massive and disseminated, sometimes chrystallized in different forms; is externally splendent, internally between shining and glistening, and has a metallic lustre. It is semihard, brittle, not very easily frangible; and when struck with steel, emits an arsenical smell. It is found in veins in various formations, in the different mine countries of the continent of Europe; and from it the greatest part of the cobalt in commerce is obtained, which is highly useful in the manufacture of glass, and as a paint.

Fourth species. Black cobalt ore.

Earthy black cobalt ore is of an intermediate colour between brownish and blueish-black, is composed of dull, dusky particles, which soil a little, usually cohering, streak shining, and very light.

Fifth species. Brown cobalt ochre

Is of a liver-brown colour, passing sometimes into other neighbouring shades; it occurs massive and disseminated, is internally dull, soft, sectile, easily frangible, and light; and appears to be peculiar to the floetz mountains in some parts of Germany and Spain.

Sixth species. Yellow cobalt ochre

Is usually of a dirty straw-yellow, occurs massive, frequently much bursten and corroded; it is internally dull, streak shining, soft, and rather friable, sectile, easily frangible, and light. It is the rarest species of cobalt ore, but most valued on account of its purity.

Seventh species. Red cobalt ochre.

Cobalt crust is of a peach blossom-red colour, of different degrees of intensity, occurs most frequently in velvety drusy coatings, and disseminated, is feebly glimmering, bordering on dull, scarcely soils, has a shining streak, and is very soft and light.

THIRTEENTH GENUS. *Nickel.*

First species. Copper nickel

Is of a red copper-colour of different degrees of intensity; it occurs usually massive and disseminated, is internally glistening, and has a metallic lustre. It is usually unseparated; sometimes, however, it is found in coarse and small granular distinct concretions, is semihard in a high degree, brittle, not very easily frangible, and heavy. Before the blowpipe it emits an arsenical smell and odour, and afterwards melts, though with difficulty. It is found in Cornwall, Norway, and many other countries, and is nearly allied to cobalt.

Second species. Nickel ochre

Is of an apple-green colour, occurs always as a coating or efflorescence, is composed of dull dusty particles, loose, or little cohering, feels meagre, and is light. It is found in the same situations with the preceding species. It is not certain that native nickel has yet been discovered, though it is mentioned by some mineralogists.

FOURTEENTH GENUS. *Manganese.*

First species. Grey manganese ore.

Radiated grey manganese ore is of a dark steel-grey colour, occurs massive, disseminated, and chrystallized in prisms of different varieties. It is found in coarse, large, and small granular distinct concretions; soils strongly when rubbed, is soft, brittle, rather difficultly frangible, and not particularly heavy. It is produced in several counties of England and Scotland, and in different parts of Germany.

Second species. Black manganese ore

Is of an intermediate colour between brownish-black and dark-greyish black, occurs massive, disseminated, and in octahedral chrystals. It is found in small and fine granular concretions; is opaque, semihard, brittle, and heavy; but is a rare mineral, and hitherto found only in a few places of Germany and Spain.

Third species. Red manganese ore

Is of a light rose-red colour, occurs massive and disseminated, is internally dull, translucent in a slight degree, hard, brittle, easily frangible, and heavy. It is found in veins in Norway, France, and some other countries.

FIFTEENTH GENUS. *Molybdena.*

First species. Molybdena.

Its colour is a fresh burning lead-grey; it occurs usually massive and disseminated, but also chrystallized in six-sided tables, and short six-sided prisms; internally it is splendent, the fracture perfectly foliated, and is found in large and coarse granular distinct concretions. It soils a little, is very soft, easily frangible, its thin leaves common flexible, sectile, feels greasy, and is heavy. It is one of the oldest of metals, and occurs only in primitive mountains, disseminated, or in veins; and is produced in Norway, Sweden, Bohemia, and other countries.

Sixteenth Genus. *Arsenic.*

First species. Native arsenic.

When fresh broken it is of a light whitish lead-grey colour, but it speedily tarnishes; it occurs massive, disseminated, reniform, and in plates, with various impressions. It is found in thin, curved, lamellar, distinct concretions; in the streak it becomes shining and metallic, semihard in a high degree, very easily frangible, and between sectile and malleable. It occurs only in primitive mountains, and in veins of a newer formation, and is found in various parts of Germany, in France, and in Chili.

Second species. Arsenic pyrites.

Common arsenic pyrites is, when fresh, of a silver-white colour, but soon acquires a yellowish tarnish; it occurs massive, disseminated, and also in chrystals of various figures. Internally, it is shining, with a metallic lustre; and is found usually unseparated, is hard, brittle, not easily frangible, and heavy. It occurs only in primitive mountains and in beds, and is produced in Norway, Germany, and Siberia. From this ore the white oxide of arsenic is principally obtained.

Third species. Orpiment.

Red orpiment is of an aurora-colour, of different degrees of intensity: it occurs massive, disseminated in membranes, and also chrystallized in oblique four-sided and six-sided prisms. It is translucent, but the chrystals are transparent, is very soft, yields a lemon or orange-coloured streak, and is easily frangible. It is found both in primitive and floetz mountains, and is produced in Germany, France, Italy, and the West Indies. It is used as a pigment.

Yellow orpiment is of a perfect lemon-yellow colour, occurs massive, and in very minute chrystals, is found in large, coarse, and small angular granulated distinct concretions, is translucent, very soft, sectile, and common flexible. It occurs principally in floetz mountains, in several parts of Germany and the East.

Fourth species. Arsenic bloom.

The colour is a reddish-white and snow-white; it occurs as a coating, in small balls, &c. and in very delicate capillary shining chrystals, is translucent on the edges, very soft, easily frangible, and soils. It is produced in rents of a granite rock, and hitherto has only been discovered in Swabia.

Seventeenth Genus. *Scheele.**

First species. Tungsten.

The colour is usually yellowish and greyish-white, which pass into several other neighbouring shades; it occurs massive, disseminated, and frequently chrystallized. Internally it is shining, with a vitreous lustre; is more or less translucent, soft, not very brittle, and uncommonly heavy. It is found in primitive mountains, and belongs to the oldest metalliferous formations, and is produced in Cornwall, Sweden, Saxony, and Bohemia.

Second species. Wolfram

Is of an intermediate colour between dark greyish-black, and brownish-black; it occurs massive, and also chrystallized in broad six-sided prisms, and rectangular four-sided tables; and is found in fortification-wise curved lamellar distinct concretions. It is opaque, yields a reddish-brown streak, is soft, brittle, and uncommonly heavy. It is produced in the primitive mountains, almost always accompanied with tin, in Cornwall, and some other countries.

* So called in honour of the illustrious Scheele.

Eighteenth Genus. *Menachine.*

First species. Menachanite

Is of a greyish-black colour, inclining to iron-black, occurs only in small flattish angular grains. Internally is glistening, with an adamantine lustre, is perfectly opaque, soft, brittle, retains its colour in the streak, is easily frangible, and moderately heavy. It is attractable by the magnet, and is found in Cornwall, accompanied by fine quartz-sand, in the isle of Providence in America, and at Botany Bay.

Second species. Octrahedrite.

Its colour passes from indigo-blue to many other shades; it occurs only chrystallized, and that in very acute octahedrons. It is chiefly translucent, and semitransparent, semihard, brittle, and borders on heavy. It is found in Dauphiny, and appears from accurate experiments to be an oxide of menachine mixed with silica.

Third species. Rutile

Is of a dark blood-red colour, of various degrees of intensity; it occurs always chrystallized in four-sided and six-sided prisms, and also in compressed acicular and capillary chrystals. Externally it is shining, internally splendent, translucent in a slight degree, hardish, easily frangible, and not very heavy. It is found imbedded in drusy cavities of granite, &c. in different parts of Germany, France, Spain, Siberia, and South Carolina.

Fourth species. Nigrine

Is of a dark brownish-black colour, passing to velvet-black; it occurs in larger and smaller angular grains, and in rolled pieces. Externally moderately glittering, internally the same, with an adamantine lustre, is opaque, semihard, brittle, and yields a yellowish-brown streak. It is found in alluvial hills in several parts of Germany, and also in Ceylon.

Fifth species. Iserine

Is of an iron-black colour, somewhat inclining to brownish-black; it occurs usually in small obtuse angular grains, and in rolled pieces, internally glistening, with a semi-metallic lustre, is completely opaque, hard, brittle, and retains its colour in the streak. Hitherto it has been found only in the stream called Iser in Germany, from which it receives its appellation. It bears a great resemblance to iron-sand.

Nineteenth Genus. *Uran.*

First species. Pitch ore

Is usually of a velvet-black colour; it occurs almost always massive and disseminated. Internally is shining, soft, brittle, uncommonly heavy, and completely infusible without addition. It is found in veins of primitive mountains along with lead and silver ores, and is produced in Saxony and Norway.

Second species. Uran mica.

The principal colour is a grass-green, passing into various allied shades; it occurs sometimes in membranes, but commonly chrystallized in rectangular four-sided tables. The fracture is foliated, the fragments and distinct concretions are too minute to be determined. It is more or less translucent, soft, sectile, easily frangible, and is found in iron-stone veins in Cornwall, Saxony, and France.

Third species. Uran Ochre.

Friable uran ochre is usually of a straw-yellow colour: it generally occurs as a coating or efflorescence on pitch ore; is friable, and composed of dull dusty particles, which feel meagre, and are not particularly heavy.

Indurated uran ore is of the same colour as the preceding: occurs massive and disseminated, is generally dull, internally opaque, soft, brittle, and soils a little, and is found along with the other ores of uran.

Twentieth Genus. *Sylvan.*

First species. Native Sylvan.

Is of an intermediate colour between white and silver-white: occurs massive and disseminated, and also chrystallized in four and six-sided prisms, in small three-sided pyramids, in cubes, and in short acicular chrystals. It is soft, not very brittle, easily frangible, and heavy; and before the blowpipe melts as easily as lead, burning with a light green colour, and emitting a sharp, disagreeable odour. Hitherto it has only been found at Face-bay, in Transylvania.

Second species. Graphic Ore.

Its colour is a light steel-grey: it occurs massive and chrystallized; externally is splendent, internally glistening. When massive, it shews a tendency to fine granular distinct concretions: it is soft, brittle, sectile, and heavy, and is worked as an ore of gold in Transylvania, where alone it has yet been found.

Third species. Yellow Sylvan Ore

Is of a silver-white colour, inclining to brass-yellow: it occurs disseminated and chrystallized in very small and rather broad four-sided prisms; is soft, rather sectile, and uncommonly heavy. It is found along with the other species of the genus, and contains a considerable portion both of gold and silver.

Fourth species. Black Sylvan Ore

Is of an intermediate colour between iron-black and blackish lead-grey: it occurs massive, and in small, thin, and longish six-sided tables, which are usually imbedded. Externally it is splendent; internally shining, soils a little, is very soft, sectile, splits easily, and in thin leaves is common flexible. It melts easily before the blowpipe; occurs in veins along with other minerals, but is only found in Transylvania, where it is worked for the gold and silver it contains.

Twenty-first Genus. *Chrome.*

First species. Acicular, or Needle Ore.

Its colour is dark steel-grey: occurs in imbedded acicular chrystals: internally shines with a metallic lustre, is soft, not very brittle, heavy, and is always accompanied with chrome ochre, and sometimes with native gold. It is found in Siberia.

Second species. Chrome Ochre

Is of a verdigris-green, passing through several neighbouring shades: it occurs massive, disseminated, and in membranes; is dull, soft, not very heavy, and is found with the preceding species.

Having already extended this article to a greater length than was intended, in order that we might be able to give a satisfactory view of the beautiful system of Werner, we shall only subjoin the names of some other minerals, which either have not been regularly classed, or are but recently discovered, and therefore have not been accurately investigated: these are

Earthy fossils, foliated prehnite, schmelzstein, spodumene, meionite, sommite, glassy felspar, spinthere, metallic fossils, pitchy iron ore, gadolinite, copper sand or muriate of copper, phosphat of copper, corneous lead ore, reniform lead ore, bournonite, columbite, tantalite, yttertantalite.

To which may be added loisite, needle or acicular-stone, fish eye-stone, iron-clay, figure-stone, granular actynolite, dolomite, foliated celestine and its varieties, silver black with its sub-species.

EXPLANATION OF PLATE II.

FIG. 1. The Icosahedron.
2. The Dodecahedron.
The Hexahedron, as
3. Cube.
4. Rhomb.
5. Rectangular tetrahedral prism.
6. Oblique-angular tetrahedral prism.
7. Oblique-angular tetrahedral prism, in which the terminal planes are set obliquely on the lateral planes.
8. Equiangular hexahedral prism.
9. Tetrahedron, or simple three-sided pyramid.
10. Double three-sided pyramid, in which the lateral planes of the one pyramid are set on the lateral edges of the other.
11. Octahedron.
12. Simple six-sided pyramid.
13. Double six-sided pyramid, in which the lateral planes of the one pyramid are set on the lateral planes of the other.
14. Double six-sided pyramid, in which the planes of the one pyramid are set obliquely on those of the other, so that the common base forms a zig-zag line.
15. Rectangular four-sided table.
16. Oblique-angular four-sided table.
17. Equiangular six-sided table.
18. Lengthened six-sided table.
19. and 20. Common lens.

Alteration of the Fundamental Figures by Truncation.

21. Cube truncated on all its angles.
22. Cube truncated on all its edges.

By Bevelment.

23. The cube bevelled on all its edges.
24. Three-sided prism having its lateral edges bevelled.
25. Oblique-angular four-sided prism bevelled on its extremities.
26. Six-sided table, with bevelled terminal planes.
27. Octahedron, with bevelled angles.

By Acumination.

28. Cube, with the angles acuminated by three planes which are set on the lateral planes.
29. Cube, with the angles acuminated by three planes which are set on the lateral edges.
30. Rectangular four-sided prism acuminated by four planes, which are set on the lateral planes.
31. Equiangular six-sided prism, acuminated on both extremities by six planes, which are set on the lateral planes.
32. Four-sided prism, acuminated on both extremities by four planes, which are set on the lateral edges.
33. Six-sided prism, acuminated on both extremities by three planes, which are set on the alternate lateral planes.
34. Six-sided prism, acuminated on both extremities by three planes, which are set on the alternate lateral edges.
35. Double eight-sided pyramid, acuminated on both extremities by four planes, which are set on the alternate lateral edges.

MINIMUM, in the higher geometry, the least quantity attainable in a given case.

MINOR, in law, is an heir, either male or female, before they arrive at the age of twenty-one; during the minority of such, they are usually incapable of acting for themselves.

MINOR, in logic, the second proposition of a regular syllogism.

MINOR, in music, signifies less, and is applied to certain concords or intervals which differ from others of the same denomination by half a tone: thus we say a third minor, meaning a less third; a sixth major and minor.

MINT, the place in which the public money is coined. See COINING.

The officers of the mint are, 1. The warden of the mint, who is chief; he oversees the other officers, and receives the bullion. 2. The master worker; who receives the bullion from the warden, causes it to be melted, delivers it to the moneyers, and when it is coined receives it again. 3. The comptroller, who is the overseer of all the inferior officers, and sees that all the money is made to the just assize. 4. The assay-master; who weighs the gold and silver, and sees that it is according to the standard. 5. The auditor; who takes the accounts. 6. The surveyor of the melting; who, after the assay-master has made trial of the bullion, sees that it is cast out, and not altered after it is delivered to the melter. 7. The engraver; who engraves the stamps and dyes for the coinage of the money. 8. The clerk of the irons; who sees that the irons are clean and fit to work with. 9. The melter; who melts the bullion before it is coined. 10. The provost of the mint; who provides for, and oversees all the moneyers. 11. The blanchers; who anneal and clease the money. 12. The moneyers; some of whom forge the money, some shear it, some round and mill it, and some stamp or coin it. 13. The porters; who keep the gate of the mint.

MINT. See MENTHA.

MINUASTIA, a genus of the triandria trigynia class and order. The cal. is 5-leaved; cor. none; caps. 1-celled, 3-valved. There are three species, herbs of Spain.

MINUTE, in geometry, the sixtieth part of a degree of a circle.

Minutes are denoted by one acute accent, thus ($'$); as the second, or sixtieth part of a minute, is by two such accents, thus ($''$); and the third by three ($'''$), &c.

MINUTE of time, the sixtieth part of an hour.

MIRABILIS, *marvel of Peru*; a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is funnel-shaped above; the calyx inferior; the nectarium globular, containing the germen. The most remarkable species are, 1. The jalapa, or common marvel of Peru. Of this there are varieties, with white flowers, with yellow flowers, with purple flowers, with red flowers, with white and yellow flowers, white and purple flowers, purple and yellow flowers, red and yellow flowers. 2. The longiflora, or long-flowered mirabilis, with all the branches and shoots terminated by white flowers in clusters, having very long tubes, nodding downward. 3. The dichotoma, dichotomous, or forked mirabilis, with smallish red flowers at the axillas, singly and close-sitting.

The roots of all these plants are purgative; but require to be given in a great quantity to operate equal to the true jalap, which is a species of convolvulus. See CONVOLVULUS.

MIRROR, a speculum, looking-glass, or any polished body, whose use is to form the images of distinct objects by reflection of the rays of light.

Mirrors are either plane, convex, or concave. The first sort reflects the rays of light in a direction exactly similar to that in which they fall upon it, and therefore represents bodies of their natural magnitude. But the convex ones make the rays diverge much more than before reflexion, and therefore greatly diminish the images of those objects which they exhibit; while the concave ones, by collecting the rays into a focus, not only magnify the objects they shew, but will also burn very fiercely when exposed to the rays of the sun; and hence they are commonly known by the name of burning mirrors.

In antient times the mirrors were made of some kind of metal; and from a passage in the mosaic writings we learn, that the mirrors used by the Jewish women, were made of brass; a practice doubtless learned from the Egyptians.

Any kind of metal, when well polished, will reflect very powerfully; but of all others, silver reflects the most, though it has always been too expensive a material for common use. Gold is also very powerful; and all metals, or even wood, gilt and polished, will act very powerfully as burning mirrors. Even polished ivory, or straw nicely plaited together, will form mirrors capable of burning, if on a large scale.

Some of the more remarkable laws and phenomena of plane mirrors are as follow:

1. A spectator will see his image of the same size, and erect, but reversed as to right and left, and as far beyond the speculum as he is before it. As he moves to or from the

speculum, his image will, at the same time, move towards or from the speculum also on the other side. In like manner if, while the spectator is at rest, an object be in motion, its image behind the speculum will be seen to move at the same rate. Also when the spectator moves, the images of objects that are at rest will appear to approach or recede from him, after the same manner as when he moves towards real objects.

2. If several mirrors, or several fragments or pieces of mirrors, be all disposed in the same plane, they will only exhibit an object once.

3. If two plane mirrors, or speculums, meet in any angle, the eye, placed within that angle, will see the image of an object placed within the same, as often repeated as there may be perpendiculars drawn determining the places of the images, and terminated without the angle. See OPTICS.

MISCHNA, or MISNA, the code or collection of the civil law of the Jews. The Jews pretend, that when God gave the written law to Moses, he gave him also another not written, which was preserved by tradition among the doctors of the synagogue, till rabbi Juda, surnamed the Holy, seeing the danger they were in, through their dispersion, or departing from the traditions of their fathers, judged it proper to reduce them to writing.

The misna is divided into six parts: the first relates to the distinction of seeds in a field, to trees, fruits, tythes, &c. The second regulates the manner of observing festivals: the third treats of women, and matrimonial cases: the fourth of losses in trade, &c. the fifth is on obligations, sacrifices, &c. and the sixth treats of the several sorts of purification. See TALMUD.

MISDEMEANOUR. A crime or misdemeanour is an act committed or omitted, in violation of a public law, either forbidding or commanding it.

MISLETOE. See VISCUM.

MISNOMER, the using of one name for another.

Where a person is described so that he may not be certainly distinguished and known from other persons, the omission, or in some cases the mistake of the name shall not avoid the grant. 11 Rep. 20.

If the christian name is wholly mistaken, this is regularly fatal to all legal instruments, as well declarations and pleadings as grants and obligations.

The mistake of the surname does not vitiate, because there is no repugnancy that a person shall have different surnames; and therefore, if a man enter into an obligation by a particular name, he may be impleaded by that name in the deed, and his real name brought in by an alias; and then the name in the deed he cannot deny, because he is estopped to say any thing contrary to his own deed. 2 Rol. Abr. 146.

MISPRISION, is generally understood to be of all such high offences as are under the degree of capital, but bordering thereon, and it is said that a misprision is contained in every treason and felony whatsoever; and, that if the king please, the offender may be proceeded against for the misprision only. 4 Black. 119.

MIS-RECITAL, in deeds, is sometimes injurious, and sometimes not; if a thing be referred to time, place, and number, and that is mistaken, all is void.

MITCHELLA, a genus of the tetrandria monogynia class and order. The cor. is 1-petalled; stigmas 4; berry trifid, 2-seeded. There is 1 species, an herb of N. America.

MITE, a small coin formerly current, equal to about one third part of a farthing.

It also denotes a small weight used by the moneyers. It is equal to the twentieth part of a grain, and is divided into twenty-four doits.

MITE. See ACARUS.

MITELLA, *bastard American sanicle;* a genus of the digynia order, in the decandria class of plants; and in the natural method ranking under the 13th order, succulentæ. The calyx is quinquefid; the corolla pentapetalous, and inserted into the calyx; the petals pinnatifid; the capsule unilocular and bivalved, with the valves equal. There are two species, both natives of North America, rising with annual herbaceous stalks from five or six to eight or nine inches in height, and producing spikes of small whitish flowers, whose petals are fringed on their edges.

MITHRIDATEA, a genus of the monandria monogynia class and order. The cal. is four-cleft; cor. none; fruit globular, depressed. There is one species, a tree of Madagascar.

MITTIMUS, a writ by which records are transferred from one court to another. This word is also used for the precept directed to a gaoler, under the hand and seal of a justice of the peace, for the receiving and safe keeping a felon, or other offender, by him committed to goal.

MIZEN, in the sea-language, is a particular mast or sail. The mizen-mast stands in the sternmost part of the ship. Its length is by some accounted the same with the height of the main-top-mast, from the quarter-deck; or half the length of the main-mast, and half as thick. The sail which belongs to the mizen-mast, is called the mizen-sail: and when the word mizen is used at sea, it always means the sail.

MNASIUM, a genus of the hexandria monogynia class and order. The cal. is 1-leaved, 3-parted; cor. 1-petalled, 3-parted; antheræ 4-cornered; germ 3-lobed; stigmas 3. There is 1 species, an aquatic of Guiana.

MNIARUM, a genus of the monandria digynia class and order. The cal. is 4-parted, superior; cor. none; seed 1. There is one species, an herb of New Zealand.

MNIUM, *marsh-moss*; a genus of the natural order of musci, belonging to the cryptogamia class of plants. The anthera is operculated; the calyptra smooth; the female capitulum naked and powdery, remote. There are 24 British species, but none have any remarkable property except the two following: 1. The fontanum is an elegant moss, frequent in bogs, and on the borders of cold springs. It is from two to four inches high: the stalks are simple at the base, and covered with a rusty down; but higher up are red, and divided into several round, single, taper branches, which proceed nearly from the same point. The leaves are not more than $\frac{1}{12}$th of an inch long, lanceolate and acute, of a whitish-green colour, and so thinly set, that the red stalk appears between them. This moss, as it may be seen at a considerable distance, is a good mark to lead to the discovery of clear and cold springs. Dr. Withering informs us, that wherever this moss grows, a spring of fresh-water may be found without much digging. 2. The hygrometricum grows in woods, heaths, garden-walks, walls, old trees, decayed wood, and where coals or cinders have been laid. It is stemless, has tips inversely egg-shaped, nodding, and bright yellow. If the fruit-stalk is moistened at the base with a little water or steam, the head makes three or four revolutions; if the head is moistened, it turns back again.

MOAT, or DITCH, in fortification, a deep trench dug round the rampart of a fortified place, to prevent surprizes.

The brink of the moat, next the rampart, is called the scarpe; and the opposite one, the counterscarpe.

A dry moat round a large place, with a strong garrison, is preferable to one full of water, because the passage may be disputed inch by inch; and the besiegers, when lodged in it, are continually exposed to the bombs, grenades, and other fire-works, which are thrown incessantly from the rampart into their works. In the middle of dry moats there is sometimes another small one, called cunette; which is generally dug so deep, till they find water to fill it.

The deepest and broadest moats are accounted the best, but a deep one is preferable to a broad one: the ordinary breadth is about twenty fathoms, and the depth about sixteen.

To drain a moat that is full of water, they dig a trench deeper than the level of the water, to let it run off; and then throw hurdles upon the mud and slime, covering them with earth or bundles of rushes, to make a sure and firm passage.

MODE, in logic, called also syllogistic mood, a proper disposition of the several propositions of a syllogism, in respect of quantity and quality.

As in all the several dispositions of the middle term, the propositions of which a syllogism consists may be either universal or particular, affirmative or negative; the due determination of these, and putting them together as the laws of argumentation require, constitute what logicians call the moods of syllogisms. Of these moods there are a determinate number to every figure, including all the possible ways in which propositions, differing in quantity or quality, can be combined, according to any disposition of the middle term, in order to arrive at a just conclusion. There are two kinds of moods, the one direct, the other indirect.

The direct mood is that wherein the conclusion is drawn from the premises directly and immediately, as, "Every animal is a living thing, every man is a living animal; therefore every man is a living thing." There are fourteen of these direct moods, four whereof belong to the first figure, four to the second and six to the third. They are denoted by so many artificial words framed for that purpose, viz. 1. Barbara, celarent, darii, ferioque. 4. Baralip, celantes, dabitis, fapesmo, frisesom. 2. Cesare, camestres, festino, baroco. 3. Darapti, felapton, disamis, datisi, bocardo, ferison. The use and effect of which words lie wholly in the syllables, and the letters of which the syllables consist; each word, for instance, consists of three syllables, denoting the three propositions of a syllogism, viz. major, minor, and conclusion: add, that the letters of each syllable are either vowels or consonants; the vowels are A, which denotes an universal affirmative; E, an universal negative; I, a particular affirmative; and O, a particular negative: thus, Barbara is a syllogism or mood of the first figure, consisting of three universal affirmative propositions: Baralip, one of the fourth figure, consisting of two universal affirmative premises, and a particular affirmative conclusion. The consonants are chiefly of use in the reduction of syllogisms. The indirect mood, is that wherein the conclusion is not inferred immediately from the premises, but follows from them by means of a conversion; as, "Every animal is a living thing, every man is an animal; therefore some living thing is a man."

Mode, in music, a particular system, or constitution of sounds, by which the octave is divided into certain intervals, according to the genus. The doctrine of the antients respecting modes is rendered somewhat obscure, by the difference among their authors as to the definitions, divisions, and names of their modes. Some place the specific variations of tones, or modes, in the manner of division, or order of the concinnous parts; and others merely in the different tension of the whole: *i. e.* as the whole series of notes are more acute or grave, or as they stand higher or lower in the great scale of sounds.

MODEL, in a general sense, an original pattern, proposed for any one to copy or imitate. This word is particularly used in building, for an artificial pattern made in wood, stone, plaster, or other matter, with all its parts and proportions, in order for the better conducting and executing some great work, and to give an idea of the effect it will have in large. In all great buildings, it is much the surest way to make a model in relievo, and not to trust to a bare design or draught. There are also models for the building of ships, &c. and for extraordinary staircases, &c.

They also use models in painting and sculpture; whence, in the academies, they give the term model to a naked man or woman, disposed in several postures, to afford an opportunity to the scholars to design him in various views and attitudes.

Models in imitation of any natural or artificial substance, are most usually made by means of moulds composed of plaster of Paris. For the purpose of making these moulds, this kind of plaster is much more fit than any other substance, on account of the power it has of absorbing water, and soon condensing into an hard substance, even after it has been rendered so thin as to be of the consistence of cream. This happens in a shorter or longer time, as the plaster is of a better or worse quality; and its good or bad properti s depend very much upon its age, to which, therefore, particular regard ought to be had. It is sold in the shops at very different prices; the finest being made use of for casts, and the middling sort for moulds. It may be very easily coloured by means of almost any kind of powder excepting what contains an alkaline salt; for this would chemically decompose the substance of it, and render it unfit for use, the gypsum or plaster being a sulphat of lime, which would be decomposed by the alkali precipitating the lime. A very considerable quantity of chalk would also render it soft and useless, but lime hardens it to a great degree. The addition of common size will likewise render it much harder than if mere water is made use of. In making either moulds or models, however, we must be careful not to make the mixture too thick at first; for if this is done, and more water added to thin it, the composition must always prove brittle, and of a bad quality.

The particular manner of making models (or casts, as they are also called) depends on the form of the subject to be taken. The process is easy where the parts are elevated only in a slight degree, or where they form only a right or obtuse angle with the principal surface from which they project; but where the parts project in smaller angles, or form curves inclined towards the principal surface, the work is more difficult. This observation, however, holds good only with regard to hard and inflexible bodies; for such as are soft may often be freed from the mould, even though they have the shape last mentioned. But though this is the case with the soft original substance, it is not so with the inflexible model when once it is cast.

The moulds are to be made of various degrees of thickness, according to the size of the model to be cast; and may be from half an inch to an inch, or, if very large, an inch and an half. Where a number of models are to be taken from one mould, it will likewise be necessary to have it of a stronger contexture than where only a few are required, for very obvious reasons.

It is much more easy to make a mould for any soft substance than a rigid one, as in any of the viscera of the animal body: for the fluidity of the mixture makes it easily accommodate itself to the projecting parts of the substance; and as it is necessary to inflate these substances, they may be very readily extracted again, by letting out the air which distended them.

When a model is to be taken, the surface of the original is first to be greased, in order to prevent the plaster from sticking to it; but if the substance itself is slippery, as is the case with the internal parts of the human body, this need not be done: when necessary, it may be laid over with linseed oil by means of a painter's brush. The original is then to be laid on a smooth table, previously greased, or covered with a cloth, to prevent the plaster sticking to it; then surround the original with a frame or ridge of glazier's putty, at such a distance from it as will admit the plaster to rest upon the table on all sides of the subject for about an inch, or as much as is sufficient to give the proper degree of strength to the mould. A sufficient quantity of plaster is then to be poured as uniformly as possible over the whole substance, until it is every where covered to such a thickness as to give a proper substance to the mould, which may vary in proportion to the size. The whole must then be suffered to remain in this condition till the plaster has attained its hardness: when the frame is taken away, the mould may be inverted, and the subject removed from it; and when the plaster is thoroughly dry, let it be well seasoned.

Having formed and seasoned the moulds, they must next be prepared for the casts by greasing the inside of them with a mixtu e of olive oil and lard in equal parts, and then filled with fine fluid plaster, and the plane of the mould formed by its resting on the surface of the table, covered to a sufficient thickness with coarse plaster, to form a strong basis or support for the cast where this support is requisite, as is particularly the case where the thin and membranous parts of the body are to be represented. After the plaster is poured into the mould, it must be suffered to stand until it has acquired the greatest degree of hardness it will receive; after which the mould must be removed: but this is attended with some difficulty when the shape of the subject is unfavourable; and in some cases the mould must be separated by means of a small mallet and chisel. If by these instruments any parts of the model should be broken off, they may be cemented by making the two surfaces to be applied to each other quite wet; then interposing betwixt them a little liquid plaster; and lastly, the joint smoothed, after being thoroughly dry. Any small holes that may be made in the mould can be filled up with liquid plaster, after the sides of them have been thoroughly wetted, and smoothed over with the edge of a knife.

In many cases it is altogether impracticable to prepare a mould of one piece for a whole subject; and therefore it must be considered how this can be done in such a manner as to divide the mould into the fewest pieces. This may be effected by making every piece cover as much of the pattern as possible, without surrounding such projecting parts, or running into such hollows as would not admit a separation of the mould. Where any internal pieces are required, they are first to be made; and then the outer pieces, after the former have become hard.

Besides the models which are taken from inanimate bodies, it has been frequently attempted to take the exact resemblance of people while living, by using their face as the original of a model, whence to take a mould; and the operation, however disagreeable, has been submitted to by persons of the highest ranks in life. A considerable difficulty occurs in this, however, from the person's being apt to shrink and distort his features when the liquid is poured upon him; neither is he altogether without danger of suffocation, unless the operator well understands his business.

To avoid the former inconvenience, it will be proper to mix the plaster with warm instead of cold water, by which means the person will be under no temptation to shrink; and to prevent any danger of a fatal accident, the following method is to be practised: Having laid the person horizontally on his back, the head must first be raised by means of a pillow to the exact position in which it is naturally carried when the body is erect; then the parts to be represented must be very thinly covered over with fine oil of almonds, by means of a painter's brush: the face is then to be first covered with fine fluid plaster, beginning at the upper part of the forehead, and spreading it over the eyes, which are to be kept close, that the plaster may not come in contact with the globe; yet not closed so strongly as to cause any unnatural wrinkles. Cover then the nose and ears, plugging first up the meatus auditorii with cotton, and the nostrils with a small quantity of tow rolled up, of a proper size to exclude the plaster. During the time that the nose is thus stopped, the person is to breathe through the mouth: in this state the fluid plaster is to be brought down low enough to cover the upper lip, observing to leave the rolls of tow projecting out of the plaster. When the operation is thus far carried on, the plaster must be suffered to harden; after which the tow may be withdrawn, and the nostrils left free and open for breathing. The mouth is then to be closed in its natural position, and the plaster brought down to the extremity of the chin. Begin then to cover that part of the breast which is to be represented, and spread the plaster to the outsides of the arms and upwards, in such a manner as to meet and join that which is previously laid on the face: when the whole of the mass has acquired its due hardness, it is to be cautiously lifted, without breaking or giving pain to the person. After the mould is constructed, it must be seasoned in the manner already directed; and when the mould is cast, it is to be separated from the model by means of a small mallet and chisel. The eyes, which are necessarily shown closed, are to be carved, so that the eye-lids may be represented in an elevated posture; the nostrils hollowed out, and the back part of the head, from which, on account of the hair, no mould can be taken, must be finished according to the skill of the artist. The edges of the model are then to be neatly smoothed off, and the bust fixed on its pedestal.

MODULATION, in music, the art of conducting harmony, in composition, or extemporary performance, through those keys and modes which have a due relation to the fundamental, or original key. Though every piece, as is well known, has its principal or governing key, yet, for the sake of contrast and relief, it is not only allowable but necessary to pass from key to key, and from mode to mode; to assume different sharps or flats, and lead the ear through those transitions of tone and harmony which interest the feelings and delight the ear. But though in grand compositions there is no quality of a greater importance than that of a masterly modulation, it is not easy to lay down rules for its accomplishment. Sometimes a gradual and almost insensible evolution of harmony is requisite to the composer's object; at other times, a bold and sudden change can alone produce the necessary effect.

MODULE. See ARCHITECTURE.

MODUS DECIMANDI, in law, is where money, land, or other valuable consideration, has been given, time out of mind, to the minister or parson of any certain place, in the room of tithes. A clergyman may sue in a spiritual court for a modus decimandi; yet if the modus is denied there, or a custom is to be tried, the trial thereof belongs to the courts of common law. When lands are converted to other uses, as in the case of hay-ground turned into tillage, the modus may be discharged, and the tithes paid again in kind.

MOERHINGIA, mossy chickweed, in botany, a genus of the octandria digynia class of plants, the flower of which is composed of four short, undivided petals; and its fruit is a subglobose capsule, with one cell, in which are contained numerous roundish seeds. There is one species.

MOLE. See ZALPA.

MOLLUGO, African chickweed; a genus of the tryginia order, in the triandria class of plants; and in the natural method ranking under the 22d order, caryophyllei. The calyx is pentaphyllous; there is no corolla; the capsule is trilocular, and trivalved. There are six species, annuals of the Cape, and of the E. and W. Indies.

MOLUCCELLA, in botany, a genus of the didynamia-gymnospermia class of plants, the flower of which is monopetalous and labiated; the upper lip being entire, and the lower one trifid: the seeds are turbinated, and contained in the bottom of the cup. One annual species.

MOLYBDATS. These salts, composed of molybdic acid combined with the alkalies and earths, were formed by Scheele; but their properties are still almost completely unknown. The supermolybdat of potass alone has been described with some detail. It is formed by detonating one part of sulphuret of molybdenum and three parts of nitre in a crucible. By dissolving the reddish mass which remains after this operation, and filtering, a solution of sulphat of potass and molybdat of potass is obtained. By evaporating the solution, the sulphat of potass is separated; when sulphuric acid is dropt into the remaining liquid, supermolybdat of potass is precipitated. This salt is soluble in water. Its solution chrystallizes by evaporation in small rhomboidal plates inserted into each other. They are bright, and have a metallic taste. When exposed to the blowpipe upon charcoal, they melt without swelling, and are converted into small globules, which are quickly absorbed by the charcoal. When melted with a mixture of phosphat of soda and of ammonia (or microcosmic salt), they communicate a green tinge. Hot water dissolves them completely, and prussiat of potass occasions in this solution a reddish brown precipitate. When a solution of muriat of tin is poured upon them, they acquire a blue colour.

MOLYBDENUM. The Greek word μολυβδαινα, and its Latin translation plumbago, seem to have been employed by the antients to denote various oxides of lead; but by the moderns they were applied indiscriminately to all substances possessed of the following properties: light, friable, and soft, of a dark colour and greasy feel, and which leave a stain upon the fingers. Scheele first examined these minerals with attention. He found that two very different substances had been confounded together. To one of these, which is composed of carbon and iron, he appropriated the word plumbago; the other he called molybdena.

Molybdena is composed of scaly particles adhering slightly to each other. Its colour is blueish, very much resembling that of lead. Scheele analysed it in 1778, and obtained sulphur and a whitish powder, which possessed the properties of an acid, and which, therefore, he called acid of molybdena. Bergman suspected this acid, from its properties, to be a metallic oxide; and at his request, Hielm, in 1782, undertook the laborious course of experiments by which he succeeded in obtaining a metal from this acid. His method was to form it into a paste with linseed oil, and then to apply a very strong heat. This process he repeated several times successively. To the metal which he obtained he gave the name of molybdenum. The experiments of Scheele were afterwards repeated by Pelletier, Ilseman, and Heyer; and not only fully confirmed, but discovered many new facts, and the metallic nature of molybdic acid was put beyond a doubt: though, in consequence of the very violent heat necessary to fuse molybdenum, only very minute grains of it have been hitherto obtained in the state of a metal. Still more lately, Mr. Hatchett has published a very valuable set of experiments, which throw much new light upon the nature of this metal.

Molybdenum is externally of a whitish-yellow colour, but its fracture is a whitish-grey. Hitherto it has only been procured in small grains, agglutinated together in brittle masses. Its specific gravity is 7.500. It is almost infusible in our fires.

When exposed to heat in an open vessel, it gradually combines with oxygen, and is converted into a white oxide, which is volatilized in small brilliant needle-form crystals. This oxide, having the properties of an acid, is known by the name of molybdic acid.

From the experiments of Mr. Hatchet, it follows that molybdenum is capable of combining with four different proportions of oxygen, and of forming four oxides; namely, 1. The black; 2. The blue; 3. The green, to which Mr. Hatchet has given the name of molybdous acid; and, 4. The yellow or white, or the molybdic acid.

1. The protoxide, or black oxide, may be obtained by mixing molybdic acid with charcoal powder in a crucible, and applying heat. A black mass remains, which is the black oxide. It seems to contain only a very minute quantity of oxygen.

2. The blue oxide may be obtained by the same process not carried so far: it is formed also whenever a plate of tin is plunged into a solution of molybdic acid.

3. The peroxide, or molybdic acid, is obtained by distilling six parts of diluted nitric acid repeatedly off native molymbdena in powder. A white mass is left behind, composed of sulphuric and molybdic acids. A little pure water washes away the sulphuric acid, and molybdic acid remains behind. This acid has at first a white colour; but when melted and sublimed, it becomes yellow.

Molybdenum combines readily with sulphur; and the compound has exactly the properties of molybdena, the substance which Scheele decompounded. Molymbdena is therefore sulphuret of molybdenum. The reason that Scheele obtained from it molybdic acid was, that the metal combined with oxygen during his process. Sulphuret of molybdenum may be formed also by distilling together one part of molybdic acid and five parts of sulphur. Molybdenum is also capable of combining with phosphorus.

Few of the alloys of this metal have been hitherto examined.

It seems capable of uniting with gold. The alloy is probably of a white colour. It combines readily with platinum in the state of an oxide. The compound is fusible. Its specific gravity is 20.000.

The alloys of molybdenum with silver, iron, and copper, are metallic and friable; those with lead and tin are powders which cannot be fused. Several other combinations have been made both by Hielm and Richter; but as the metals which they tried were alloyed not with molybdenum, but with molymbdic acid, they cannot be considered as by any means the same with the alloys formed by molybdenum itself.

Molybdenum, *Ores of.* These are very scarce, having been found only in Sweden, Germany, Carniola, among the Alps, near Inverness, and in the island of Lewis, in Scotland. The only species known is molybedna, which is found commonly massive: sometimes, however, it is chrystallized in hexædral tables. Colour light lead-grey; sometimes with a shade of red. Streak blueish-grey, metallic. Powder blueish texture, foliated lamellæ, slightly flexible. Specific gravity 4.5 to 4.73. Marks blueish-black. A piece of resin rubbed with this mineral becomes positively electric. Insoluble in sulphuric and muriatic acids. Composed of about

60 molybdenum
40 sulphur
———
100

MOMENT, in the doctrine of infinites, denotes the same with infinitesimal.

Moment, momentum, in mechanics, signifies the same with impetus, or the quantity of motion in a moving body; which is always equal to the quantity of matter, multiplied into the velocity; or, which is the same thing, it may be considered as a rectangle under the quantity of matter and velocity.

MOMORDICA, male balsam apple; a genus of the syngenesia order, in the monœcia class of plants; and in the natural method ranking under the 34th order, cucurbitaceæ. The male calyx is quinquefid; the corolla sexpartite; the filaments are three in number. The female calyx is trifid; the corolla quinquepartite; the style trifid; the fruit is an apple parting asunder with a spring. There are eight species, the most remarkable of which are, 1. The balsamina, or male balsam apple. This is a native of Asia; and has a trailing stalk like those of the cucumber or melon, with smooth leaves, cut into several segments, and spread open like a hand. The fruit is oval, ending in acute points, having several deep angles, with sharp tubercles placed on their edges. It changes to a red or purplish colour when ripe, opening with elasticity, and throwing out its seeds. 2. The elaterium, wild or spurting cucumber, has a large fleshy root, somewhat like briony, whence come forth, every spring, several thick, rough, trailing stalks. The flowers come out from the wings of the stalks: these are male and female, growing at different places on the same plant like those of the common cucumber: but they are much less, of a pale yellow colour, with a greenish bottom; the male flowers stand upon thick, short, foot stalks, but the female flowers sit upon the young fruit; which, after the flower is faded, grows of an oval form, an inch and a half long, swelling like a cucumber, of a grey colour, like the leaves, and covered over with short prickles. This species has one of its names from the property of casting out its seeds, together with the viscid juice in which the seeds are lodged, with a violent force, if touched while ripe.

The first species is famous in Syria for curing wounds. The natives cut open the unripe fruit, and infuse it in sweet oil, which they expose to the sun for some days, until it becomes red; and then present it for use. Dropped on cotton, and applied to a fresh wound, the Syrians reckon this oil the best vulnerary next to balsam of Mecca, having found by experience that it often cures large wounds in three days. The leaves and stems of this plant are used for arbours or bowers. The elaterium of the shops is the fruit, or rather the inspissated fæcula, of the juice of the unripe fruit of the wild cucumber. It is usually sent us from Spain and the southern parts of France, where the plant is common. We receive it in small, flat, whitish lumps, or cakes, that are dry, and break easily between the fingers. It is of an acrid, nauseous, bitter taste, and has a strong offensive smell when newly made; but these, as well as its other properties, it loses, after being kept for some time. It is a very violent purge and vomit, and is now but seldom used.

MOMOTUS, a genus of birds of the order picæ. The generic character is, bill strong, slightly curved, serrate at the edges; nostrils feathered; tongue feathered; tail wedged; feet formed for walking. There is but one species, the Brasiliensis, that inhabits Brasil; size of a blackbird; eighteen inches long; lives solitarily in unfrequented forests; building a nest of dry grass on the ground, or in holes abandoned by the armadillo, and lays two eggs; feeds on insects and raw flesh, the fragments of which it macerates in water; when taken, it strikes violently with its bill. Its voice is harsh, weak, tremulous.

MONADELPHIA, (from μονος *alone*, and αδελφια a *brotherhood;*) a "single brotherhood." The name of the 16th class in Linnæus's sexual system, consisting of plants with hermaphrodite flowers; in which all the stamina, or male organs of generation, are united below into one body or cylinder, through which passes the pointal or female organ. See Botany.

MONANDRIA, (from μονος *alone*, and ανηρ a *man* or *husband:*) The name of the first class in Linnæus's sexual system; consisting of plants with hermaphrodite flowers, which have only one stamen or male organ.

MONARDA, Indian horehound; a genus of the monogynia order, in the diandria class of plants; and in the natural method ranking under the 42d order, verticillatæ. The corolla is unequal, with the upper lip linear, involving the filaments; there are four seeds. There are seven species; the most remarkable is the didyma, a native of North America. It is herbaceous. The flowers, which are of a bright red, surround the stalk in whorls, each whorl containing about 14 flowers; and are succeeded by four small kidney-shaped shining seeds, lodged in the bottom of the permanent flower-cup. The Indians superstitiously believe that a fumigation of this plant is effectual for driving away the devil.

MONAS, a genus of vermes, order infusoria. The generic character is worm invisible to the naked eye, most simple, pellucid, resembling a point. There are five species: the termo is a most minute, simple gelatenous point: to be found in most animal and vegetable infusions: of all animals the most minute, being so extremely delicate and transparent, as often to elude the most highly magnifying powers, blending in a manner with the water in which it swims.

MONETIA, a genus of the class and order tetrandria monogynia. The cal. is four-cleft; petals four; berry two-celled; seeds solitary. There is one species, a shrub of the E. Indies.

MONEY. The æra of the invention of money is not easy to be settled. There is no room to doubt, but that in the earliest ages the ordinary way of traffic among men was by trucking or exchanging one commodity for another; but in course of time it was found necessary, in the way of commutative justice, to have some common measure or standard, according to which all things should be estimated.

Money is usually divided into real and imaginary. Real money includes all coins, whether of gold, silver, copper, or the like; such as guineas, crowns, pistoles, pieces of eight, ducats, &c. for an account of which we refer the reader to the article Coin.

Imaginary money, or money of account, is that which never existed, or, at least, which does not exist in real specie; but is a denomination invented or retained to facilitate the stating of accounts, by keeping them still on a fixed footing, not to be changed like current coins, which the authority of the sovereign sometimes raises or lowers, according to the exigencies of the state, of which kinds are pounds, livres, marks, maravedies, &c. See Pound, &c.

No person is obliged to take in payment any money which is not lawful metal, that is, of silver and gold, except for sums under sixpence. 2 Inst. 577.

But it was decided in Hilary term, 1790, that bank notes were considered as money, and therefore a proper tender in payment.

English Money *of account*, is the pound, shillings, and pence; the pound contains twenty shillings, and the shilling twelve pence.

The old Scotch Money *of account* was the pound, shilling, and penny; the pound containing twenty shillings, being equivalent to one shilling and eightpence English; and the shilling containing twelve pennies, equal to a penny English. There is also among them an account of marks, the mark being equivalent to one shilling $1\frac{1}{3}$ penny English: of this last kind they had formerly a silver coin.

French Money *of account*, in France, sous, cents, &c.

Dutch MONEY *of account*, is kept at Amsterdam and Rotterdam, the two chief trading places, in guilders, stivers, and penins; so that though goods are sold for other species, such as livre de gros, &c. yet all are reduced to the above denominations for the entries into their books. The exchanges are made with us in so many shillings to a pound sterling, though in most other places in deniers-de-gros.

Spanish MONEY *of account*, is at Cadiz kept in rials of plate and its fractions; at Castile, in maravedies; at Valencia, in livres or dollars, sueldos and dineros; of which last twelve make a sueldo, and twenty sueldos a livre or dollar. Seventeen quartos, at Cadiz and Castile, make two rials vellon, which is now an imaginary coin, though formerly it was the principal one of the kingdom. A maravedie is another imaginary specie, of which seventeen is reckoned to a rial vellon. The ducat is also a fictitious coin of eleven rials of plate in purchases, sales, and other mercantile transactions, except in exchanges, when it is valued at eleven rials of plate and one maravedie, or 575 maravedies.

Portuguese MONEY *of account*, is kept in reas, or res, making a separation at every hundred, thousandth, &c. 800 reas go to a moidore.

German and Swiss MONEY *of account*. At Coningsberg, Elbing, and Dantzic, accounts are kept in rixdollars and gros, or in Polish guilders, gros, and deniers, or penins. They exchange on Amsterdam in Polish gros for a livre de gros of six guilders current money of Amsterdam, and on Hamburg for the rixdollar. At Lubec, accounts are kept in marks, schellings, and deniers or penins-lubs, in which their exchanges are made. At Breslaw, accounts are kept in rixdollars and silver gros and penins; in the first of which species exchanges are made on Amsterdam for a certain number of stivers, bank money, and on Hamburg for rixdollars of Breslaw against rixdollars of Hamburg bank. At Hamburg, accounts are kept in marks, schellings, and deniers-lubs bank money, by those who have cash in the bank; but by those who have not, their books are generally kept in rixdollars, schellings, and denier current money. At Bremen, accounts are kept in rixdollars and gros, and it exchanges on Amsterdam rixdollars of seventy-gros for rixdollars of fifty stivers banco. At Leipsic and Naumbourg, accounts are kept in rixdollars, crowns, gros, and penins. At Berlin, and in all this kingdom, accounts are kept in guilders, gros, and penins. At Zurich, accounts are kept in rixdollars, creutzers, and hellers; reckoning their rix dollars (worth about 4*s*. 6*d*. sterling) at 108 of their creutzers. At Frankfort on the Maine, and Hanaw, accounts are kept in rixdollars and creutzers. At Vienna, accounts are kept in guilders, creutzers, and penins, reckoning eight penins to a creutzer, and sixty creutzers to a guilder. At Nuremberg and Augsbourg, accounts are kept in guilders, creutzers, and hellers; at Liege, in livres, sols, and deniers.

In the canton of St. Gall, in Switzerland, accounts are kept in guilders, creutzers, and penins; or under the same denomination with the coins of the empire. In the canton of Basil, accounts are variously kept, some in rixdollars, schellings, and deniers; some in livres, schellings, and deniers; some in rixdollars, creutzers, and penins; and some in guilders, creutzers, and penins.

Italian MONEY *of account*. In the cities of Genoa and Novi, accounts are kept in livres, soldi, and denari; or in dollars of 100 soldis. At Milan, accounts are kept in livres, soldis, and denari, to be counted like pounds, shillings, and pence, viz. twelve denaris to a soldi, &c. At Rome, accounts are kept in crowns, julios, and bajoches, or grains and quartrins; the crown is divided into ten julios, and the julio into ten bajoches. At Leghorn, accounts are generally kept in dollars, soldi, and denari. At Florence, they keep their books and accounts in crowns, soldi, and denari, picoli or current money. At Naples, accounts are kept in ducats, florins, and grains. The accounts in Sicily are kept the same as at Naples. At Lucca they keep their accounts in crowns, livres, soldi, and denari; the crown is worth 7 livres 10 soldi; the livre, 20 soldi; and the soldi, 12 denari. At Venice, accounts are kept in livres, soldi, and denari, picoli or current; but the bank-entries are in livres, soldi, and grosses: both the current and bank-ducats of Venice make 24 soldi, or six livres and 4 soldi. At Bologna, accounts are kept in livres, soldi, and denari; the livre being 20 soldi, and the soldi 12 denari. At Bergam, the money of account is the same as at Bologna, and its proportions the same. At Parma accounts are kept in crowns, soldi, and denari; the crown is 20 soldi, and the soldi 20 denari. At Modena and Mantua, accounts are kept in livres, soldi, and denari. In Savoy and Piedmont, accounts are kept in livres or lires, soldi, and quartrins. At Placentia, accounts are kept in crowns, soldi, and denari of mark; of which 12 denari make a soldi, and 20 soldi the crown. In the island of Sardinia, accounts are kept as in most parts of Italy, in livres, soldi, and denari. In the island of Malta, the money of account is the same with that of Sicily. In the island of Candia, the account is the same as at Venice.

Russian, Swedish, Danish, and Polish MONEY *of account*. In the trading places of the Russian empire, accounts are kept in roubles, grives, and moscosques, or in roubles and coppecks; 10 coppecks (each of which is equal to 2 moscosques) make a grive, and 100 coppecks, or 10 grives, is a rouble. In the kingdom of Sweden, accounts are kept in dollars, marks, and oorts; the dollar being worth 4 marks, and the mark 8 oorts. In Denmark, accounts are kept in marks and schellings: the rixdollar is worth 6 marks; the mark, 16 schellings; and the schelling, 3 penins. Accounts are kept at Bergen, and in other places in Norway, in Danish rixdollars, marks, and schellings. In Poland, accounts are kept in guilders, gros, and deniers, of which 18 deniers make a gros, and 30 gros a guilder: they here keep accounts also in rixdollars and gros, reckoning 90 of the latter to one of the former. At Riga, accounts are kept in rixdollars and gros, the former of which species consists of 90 of the latter.

Turkish MONEY *of account*. The Turks, both in Europe, Asia, and Africa, account by purses, either of silver or gold (the last being only used in the seraglio), with half purses of gold, called also rizes: the purse of silver is equal to 1500 French livres, or about 65*l*. sterling; and the half purse in proportion: the purse of gold is 15,000 sequins, equal to 30,000 French crowns, or about 3,750*l*. sterling: this is seldom used but for presents to favourites, so that a purse simply signifies a purse of silver, or 1,500 livres. The merchants also use Dutch dollars, called astani or abouquels, with medins and aspers: the dollar is equal to 35 medins, and the medin to 3 aspers; the asper to a halfpenny sterling money.

Asiatic MONIES *of account* are as follow. In Persia, they account by the taman (called also man and tumein) and dinar-bisti; the taman is composed of 50 abassis, or 100 mamodies, or 200 chapes, or 10,000 dinars; which, accounting the abassi on the foot of 18 French sols, or the dinar or that of a denier, amounts to 3*l*. 12*s*. 6*d*. sterling the taman. They also account by larins, especially at Ormus, and on the coast of the Persian gulph: the larin is equivalent to 11*d*. sterling; and on that footing is used also in Arabia, and through a great part of the East-Indies. Chinese moneys of account are the pic, picol, and tael; which, though in effect weights, do likewise serve as money of account, obtaining in Tonquin as well as China: the pic is divided into 100 catis, some say 125; the cati into 16 taels, each tael equal to one ounce two drachms: the picol contains 66¾ caties; the tael is equivalent to 6*s*. 8*d*. sterling.

Japanese moneys of account are the schuites, cockiens, oebans or oubans, and taels: 200 schuites are equal to 500 Dutch pounds, the cockien equal to 10 low-country pounds, 1000 oebans make 45,000 taels.

Mogul money of account: at Surat, Agra, and the rest of the estates of the great mogul, they use lacres, acrees, or leeths, implying one hundred thousand; thus a lacre of rupees is 100,000 rupees; the lacre being nearly on the footing of the tun of gold in Holland, and the million of France.

Monies of account of other islands and coasts of India. Throughout Malabar, and at Goa, they use tangas, vintins, and pardos-xeraphim: the tanga is of two kinds, viz. of good and bad alloy; hence their custom is to count by good or bad money; the tanga of good alloy is better by one-fifth than the bad, so that 4 tangas good being allowed the pardos-xeraphim, there will be required 5 of the bad; 4 vintins good make a tanga likewise good; 15 barucos, a vintin; a good baruco is equal to a Portuguese ree, a French denier, or one-thirteenth of a penny sterling. In the island of Java they use the santasapacou, fardos, and catis; which last money, together with the leeth or lacre, is much used throughout all the East Indies: the santa is 200 caxas, or little pieces of that country, hung on a string, and is equal to eleven-twelfths of a penny sterling: five sentas make the sapacou. The fardos equal to 2*s*. 8*d*. sterling; the cati contains 20 taels; the tael 6*s*. 8*d*. sterling. There are islands, cities, and states, of the East Indies, whose monies of account are not here expressed, partly because reducible to some of the above-mentioned, and partly because we find no certain consistent account of them.

African Money *of account*. From Cape Verd to the Cape of Good Hope, all exchanges and valuations of merchandize are made on the foot of the macoute and piece; which, though no monies of account (for those barbarians have no real monies, and therefore need no imaginary ones to estimate them by) yet serve in lieu thereof. At Loango de Boirie, and other places on the coast of Angola, the estimations are made by macoutes; and at Malimbo and Cabindo, on the same coast, the negroes reckon by pieces: among the first the macoute is equal to 10 pieces; ten macoutes make 100, which likewise gives us a kind of imaginary money, to estimate any purchase, exchange, &c. they fix on the one side the number of macoutes required; *e. gr.* for a negro; so that there are several bargains made for one; suppose, for instance, the slave to be fixed at 3,500 pieces, this amounts to 350 macoutes; to make up this number of macoutes in merchandize, they fix the price of each in macoutes. Two Flemish knives, *ex. gr.* are accounted one macoute; a copper bason, 2 pound weight, three; a barrel of gunpowder, three, &c. For the piece, it serves in like manner to estimate the value of goods, duties, &c. on either side: thus the natives require 10 pieces for a slave; and the Europeans put, for instance, a fusee at 1 piece, a piece of salampours at 4 pieces, &c. The cities of Barbary and Egypt, whither the Europeans traffic, reckon much after the same manner as in the Levant and the dominions of the grand seignor; for the rest, through that vast extent of coast where we trade for negroes, gold-dust, elephant's teeth, wax, leather, &c. either the miserable inhabitants do not know what money of account is, or, if they have any, it is only what strangers, settled among them, have introduced.

Monies *of account in America*. Here they have no money of their own; the respective monies of account of the Europeans, who have made settlements there, being established among them.

MONKEY. See Simia.

MONOCHORD, a musical instrument, composed of one string, used to try the variety and proportion of sounds.

It is formed of a rule, divided and subdivided into several parts, on which there is a moveable string stretched upon two bridges at each extreme. In the middle between these is a moveable bridge, by means of which, in applying it to the different divisions of the line, the sounds are found to bear the same proportion to each other as the division of the line, cut by the bridge. There are also monochords with forty-eight fixed bridges. The following is the account of a monochord invented by earl Stanhope:

1. The wire is not made either of brass or of iron, but of steel, which is very far superior. For, steel wire does not keep continually lengthening, as brass and iron wires do when they are stretched considerably. 2. The wire in this monochord does not, as usual, pull downwards on the bridges, but the whole wire forms one straight and horizontal line, by which means the moveable bridge, which determines the exact length of the wire, can be moved without altering the tension of the wire. This is not the case when the wire pulls downwards on the bridges. 3. The ends of the wire are not twisted round the two stout steel pins which keep it stretched; but each end of the wire is soft-soldered in a long groove formed in a piece of steel which goes over its corresponding pin. This is a great improvement. 4. One of those two steel pins is strongly fastened on a brass slider, which is moved by means of a screw with very fine threads, which screw has a large micrometer head minutely divided on its edge, and a corresponding nonius; so that the tension of the wire may be adjusted with the greatest precision, in order to obtain its exact pitch. 5. A slider is fixed across the top of the moveable bridge, and is moved by means of another screw with very fine threads; so that the length of the wire may be regulated with the greatest nicety in all cases. 6. The above-mentioned slider, which is on the top of the moveable bridge, is adjusted to the steel rod or scale, not by sight, or by the coincidence of lines, but by means of mechanical contact against projecting pieces of steel firmly fixed on that steel scale, which method is incomparably more correct. 7. Each bridge carries a metallic finger, which keeps the wire close to the top of the bridge, whilst the wire is made to vibrate. 8. The vibrations of the wire are produced by touching it with a piece of cork, with the same elastic force, and on the very same spot each time, namely, at the distance of one inch from the immoveable bridge.

MONNIESIA, a genus of the class and order, diadelphia pentandria. The calyx is five-parted; corolla stringent; stamina 3, capsules 5, 1-seeded. There is one species, an American annual.

MONOCULOS. Monoculus, a genus of the order aptera: the generic character is, feet formed for swimming; body covered by a crustaceous tegument; eyes, in most species, approximated, and imbedded in the shell.

Of the monoculi, by far the major part are very small water-insects, requiring the assistance of a microscope for the investigation of their particular organs: some however are so large as to require no very minute inspection; and one species in particular, (if, indeed, it can be allowed to stand with propriety in the genus) is of a size so gigantic, that it is generally considered as the largest of the crustaceous tribe. This animal is the monoculus polyphemus of Linnæus, commonly distinguished by the title molucca or king-crab. Specimens are sometimes seen of two feet in length, exclusive of the tail. It is a native of the Indian ocean, and is said to be generally found in pairs, or male and female swimming together. The colour of the whole animal is a yellowish-brown: the shell is very convex, rounded in front, and lunated behind, where it joins the lower part of the body: this, which is of the same crustaceous nature, is marked on each side into several spiny incisions; the legs, which are seven on each side, are situated beneath the concavity of the large or rounded part of the shell, and are each terminated by a double claw, those of the lowest pair having some additional processes: the branchiæ, or respiratory, organs are disposed in the form of several flat, rounded, imbricated lamellæ on each side the lower part of the body; the tail, which is strait, triangular, and of the same crustaceous nature with the rest of the shell, is equal in length to the whole body, and gradually tapers to a sharp point. The eyes in this species, instead of being approximated, as required in the Linnæan generic character, are extremely distant from each other, being situated towards the sides of the shell: they are of a semilunar form, and the surface is divided into a great number of minute conical convexities: this part however should be considered as only constituting the cornea or exterior covering of each eye; the organs themselves being, according to the observations of Mr. Petiver, in the Philosophical Transactions, placed on a pedicle beneath each of the above-mentioned semilunar corneæ. Petiver's words are these. "The whole structure of this animal is very remarkable, and particularly his eyes, viz. between the fourth and last pair of claws on each side, reckoning from his mouth, and excluding the small pair there placed, are inserted the rudiments of another pair, or a claw broken off on each side at the second joint or elbow; on these extremities are the eyes, like those of the horns of snails, but under the covert of a thick and opaque shell, Nature in that place has wonderfully contrived a transparent lantern, through which the light is conveyed, whose superficies very exactly resembles the great eyes of our large libellæ or adderbolts, which to the naked eye are plainly perceived to be composed of of innumerable globuli: these, like them, are oblong, and guarded by a testaceous supercilium."

Of the European monoculi, by far the largest is the monoculus apus, which, when full-grown, measures nearly an inch and three quarters from the front to the end of the body, exclusive of the forked divisions of the tail. It is found in muddy stagnant waters, but is a rare species in this country, having been only observed in a few particular situations. In its general shape, it is considerably allied to the large exotic species before described, but the body is of a more lengthened form in proportion, with the hinder part naked, and divided into numerous joints: the branchiæ, or respiratory organs, are large, and are distributed into numerous imbricated rows on the under part of the body: beneath the front is a pair of jointed, trifid arms, extending on each side to a considerable distance; the eyes are placed near each other in front of the shell: the tail is terminated by a pair of long forks or cetaceous processes. The colour of the whole insect is a pale greenish-brown above, and reddish beneath. We are informed in vol. 40 of the Philosophical Transactions that this insect has been found in great plenty in a pond on Bexley's common, in Kent. It is also added that the same pond, having been perfectly dried, and being suddenly filled during a heavy thunder-storm, swarms of the same animal were again observed in it within the space of two days after.

Monoculus pulex, called, from its peculiar starting or springing motion, the water-flea, is an almost universal inhabitant of stagnant waters, appearing sometimes in such vast swarms as to cause an apparent discoloration of the water itself. It is an insect of a highly singular and elegant appearance, exhibiting, when magnified, a beautiful distribution of internal organs. Its general length is about the tenth of an inch, but it is sometimes seen considerably larger: its shape is oval, somewhat truncated in front, and sharply pointed behind: the body is inclosed in a bivalve, transparent shell, which, when examined by the microscope, appears finely reticulated: on each side the head is a strong transparent jointed arm, forking into two divisions, and terminating in several cetaceous branches: the tail, which is generally inclosed within the shell, is occasionally protruded in the form of a strong curved and pointed process: the eyes of this animal are of a singular construction; they are large in proportion to the insect, placed very near each other, appear to consist of many separate globules, of a black colour united under a common skin.

MONODON MONOCEROS, UNICORN NARWHAL, is a native of the northern seas, where it is sometimes seen of the length of more than twenty feet from the mouth to the tail; and is at once distinguishable from every other kind of whale by its very long, ivory-like tooth, which is perfectly straight, of a white or yellowish-white colour, spirally wreathed throughout its whole length, and gradually tapering to a sharp point. It measures from six to nine or ten feet in length, and proceeds from a socket on the one side of the upper jaw, having a large cavity at its base or root, running through the greater part of the whole length. In the young animals and occasionally even in the full grown ones, more especially in the males, there are two of these teeth, sometimes nearly of equal length, and sometimes very unequal in this respect: they are seated very close to each other at the base, and as their direction is nearly in a straight line, they diverge but little in their progress towards the extremites. The head of the narwhal is short, and convex above; the mouth small; the spiracle or breathing-hole duplicated within; the tongue long; the pectoral fins small; the back, finless, widish, convex, becoming gradually accuminated towards the tail, which, as in other whales, is horizontal. The general form of the animal is rather long than thick in proportion to its size. The colour, when young, is said to be nearly black, but lighter on the belly: but as the animal advances in age, it becomes marbled or variegated with black and white on the back and sides, while the belly is nearly white. The skin is smooth, and there is a considerable depth of oil or blubber beneath it.

The narwhal chiefly inhabits the northern parts of Davis's Streights. Its food is said to consist of the smaller kind of flat-fish, as well as of actiniæ, medusæ, and many other marine animals. It is principally seen in the small open or unfrozen spots towards the coasts of the northern seas. To such places it resorts in multitudes, for the conveniency of breathing, while at the same time it is sure of finding near the shores a due supply of food, and is very rarely seen in the open sea. It is taken by means of harpoons, and its flesh is eaten by the Greenlanders, both raw, boiled, and dried: the intestines and oil are also used as a food; the tendons make a good thread, and the teeth serve the purpose of hunting-horns as well as the more important ones of building tents and houses: but before this animal became distinctly known to the naturalists of Europe, they were held in high estimation, as the supposed horns of unicorns. Various medical virtues were also attributed to them, and they were even numbered among the articles of magnificence. A throne made for the Danish monarchs is said to be still preserved in the castle of Rosenberg, composed entirely of narwhals' teeth; the material being antiently considered as more valuable than gold.

A specimen of this whale, measuring about eighteen feet, exclusive of the horn or tooth, was some time ago stranded on the coast of Lincolnshire, at no great distance from Boston, and was said to have been taken alive.

2. Monodon spurius, spurious narwhal. A species most allied to the narwhal, but not perhaps, strictly speaking, of the same genus: no teeth in the mouth, but from the extremity of the upper mandible project two minute, conic, obtuse teeth, alike curved at the tips, weak, and not above an inch long: body elongated, cylindric, black. Besides the pectoral fins, and horizontal tail, is also a minute dorsal fin. It must be numbered among the rarest of the whales. Its flesh and oil are considered as very purgative: inhabits the main ocean, seldom coming towards shore: feeds on the loligo: has a spiracle like other whales. Both flesh and oil are eaten, but not without apprehension, for the reason already mentioned.

MONODON narwhal, a genus of mammalia of the order cete; the generic character is, teeth two in the upper jaw, extending straight forward, long, spiral: spiracle on the fore and upper part of the head. It inhabits the Atlantic, swims rapidly, and is from 18 to 40 feet long and 12 broad. Skin white, spotted on the back with black: dorsal fins: pectoral, two small: head small: eyes very minute: what are commonly exhibited as the unicorns horns. See Plate Nat Hist. fig. 269.

MONOECIA, from μονος alone, and οικια, a house; the name of the 21st class of Linnæus's sexual method. See BOTANY.

MONOGYNIA from μονος alone, and γυνη a woman; the name of the first order or subdivision in the first 13 classes of Linnæus's sexual method; consisting of plants, which, besides their agreement in their classic character, generally derived from the number of their stamina, have only one style, or female organ. See BOTANY.

MONOGRAM, a character or cypher, composed of one, two, or more letters interwoven; being a kind of abbreviation of a name, antiently used as a seal, badge, arms, &c.

MONOPOLY, is an allowance by the king, by his grant, commission, or otherwise, to any person or persons, bodies politic or corporate; or of, or for, the sole buying, selling, making, working, or using of any thing, whereby any person or persons, bodies politic or corporate, are sought to be restrained of any freedom or liberty they had before, or hindered in their lawful trade. 3 Inst. 181.

But it seems that the king's charter, impowering particular persons to trade to and from such place is void, so far as it gives such persons an exclusive right of trading, and debarring all others; and it seems now agreed, that nothing can exclude a subject from trade but an act of parliament. Raym. 489.

MONOPTERUS. Monoptere, a genus of the fishes of the order apodal; the generic character is, body anguilliform; nostrils placed between the eyes; fin caudal.

1. The monopterus Javanicus, the only animal of this genus hitherto discovered, is thus described by the count de la Cepede, from the manuscripts of Commerson, by whom it was considered as a species of Muræna. The body is serpentiform, viscous, and destitute of conspicuous scales: the head thick, compressed, enlarging towards the back part, and terminated in front by a rounded muzzle: the gape is rather wide; the upper jaw scarcely projecting beyond the lower; both being furnished with close teeth: the gill membrane has only three rays, and the branchiæ are only three in number on each side; the lateral line, which is nearer the back than the belly, extends from the gills to the extremity of the tail, and is almost of a gold-colour: the back is of a livid brown or blackish colour. This fish is a native of the Indian seas and is very common about the coasts of Java, where it is considered as an excellent food.

MONSONIA, a genus of the dodecandria order, in the polyadelphia class of plants. The calyx is pentrophyllous; the corolla pentapetalous and irregular; the stamina are 15 in number, and coalited into five filaments; the style bifid; the capsule pentacoccous. There are three species.

MONSOON. See WIND.

MONTH, the twelfth part of a year. See CHRONOLOGY.

MONTIA, water chickweed, a genus of the trigynia order, in the triandria class of plants; and in the natural method ranking with those two of which the order is doubtful. The calyx is dyphyllous; the corolla monopetalous and irregular; the capsule unilocular and trivalved. There is one species.

MOOD, or *Mode*, in grammar, the different manner of conjugating verbs, serving to denote the different affections of the mind.

MOON. See ASTRONOMY.

MOONSTONE. This is the purest felspar hitherto found. It occurs in Ceylon and Switzerland; and was first mentioned by Mr. Pini. Specific gravity, 2.559. Colour white; sometimes with a shade of yellow, green, or red. Its surface is sometimes iriddescent. A specimen of it analysed by Vauquelin, yielded.

MOORING, in the sea-language, is the laying out the anchors of a ship in a place where she can ride secure. Mooring across, is laying out on each side; and mooring along, is to have an anchor in a river and a hawser on shore. When ships are laid up in ordinary, or are under orders of fitting for sea, the moorings are laid out in harbours; and consist of claws, pendant chains, cables, bridles, anchors, swivels, jews-harps, buoys, and chains.

MORDELLA, a genus of insects of the order coleoptera. The antennæ are thread-shaped and serrated; the head is deflected under the neck: the pappi are elevated, compresed, and obliquely blunted; and the elytra are bent backwards near the apex. There are six species.

MORÆA, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the 6th order, ensatæ. The corolla is hexapetalous; the three interior petals, patent; the rest like those of the iris. There are 17 species, beautiful exotics, resembling the iris.

MORINA, a genus of the monogynia order, in the triandria class of plants; and in the natural method ranking under the 48th order, aggregatæ. The corolla is unequal; the calyx of the fruit is monophyllous and dented; the calyx of the flower bifid; there is one seed under the calyx of the flower. There is one species.

MORINDA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under the 48th order, aggregatæ. The flowers are aggregate and monopetalous; the stigmata bifid; the fruit plums aggregate or in clusters. There are 3 species, trees of the East Indies.

MORISONIA, a genus of the polyandria order, in the monadelphia class of plants; and in the natural method ranking under the 25th order, putamineæ. The calyx is single and bifid; the corolla tetrapetalous; there is one pistil: the berry has a hard bark, is unilocular, polyspermous, and pedecellated. There is one species, a tree of South America.

MORMYRUS, a genus of fishes of the branchiostegeous order, the generic character is, head smooth; teeth numerous, notched; aperture of the gills linear, without a cover; gill membrane with one ray; body scaly. There are three species. The kannume has the tail bifid, obtuse; dorsal fin with 63 rays. It inhabits the Nile; body whitish and much compressed.

MOROCCO, *maroquin*, in commerce, a fine kind of leather prepared of the skin of an animal of the goat-kind, and imported from the Levant, Barbary, &c.
